RAGWORT is the vulgar name of a plant called Senecio *Jacobæa*, which is so called from the ragged appearance of the leaves. It is a mere weed of no beauty; but the name is often applied to *Senecio elegans*, a Cape annual with purple flowers, which was formerly a common ornament of gardens.

RAIKES, ROBERT. [SUNDAY SCHOOLS.]

RAIL. (Ornithology.) [RALLIDÆ.]

RAILWAY, a road in which smooth tracks of wood, iron, or other suitable material are laid to facilitate the motion of wheel-carriages. Railways are of various kinds, and have been used for a very considerable time as a means of transport for minerals and heavy goods; and recently, in conjunction with locomotive steam-engines, have been introduced to a very important extent for the purposes of general conveyance.

As the construction of railway carriages and the power made use of for drawing or propelling them are subjects intimately connected with that of the formation of the road itself, it appears desirable to treat of the whole in one article. It is here intended therefore to present a sketch of the progress of inventions relating to railways; an account of the designing, executing, and mode of working a line intended for general traffic; and a condensed description of the principal railways completed or in progress in this and other countries.

History.—Though some writers, in attempting to trace the origin of railways, have gone back to an earlier period, it does not appear that any satisfactory notice of what may fairly be considered as such is to be found before the seventeenth century, in the early half of which wooden rail, trams, or waggon ways were introduced in the collieries of the north of England. They were adopted in order to reduce the labour of drawing coals from the pits to the places of shipment in the neighbourhood of Newcastle-upon-Tyne, and they consisted, in the first instance, simply of pieces of wood imbedded in the ordinary road, in such a manner as to form wheel-tracks for the carts or waggons employed. The wooden tracks presented a much smoother surface for the wheels to roll upon than the very imperfect roads previously used, and therefore greatly increased the available power of the horses. The advantages even of this rude kind of railway were so great as to cause its extensive introduction in various mining districts, and in course of time several improvements were made upon it. About 1765, from a hundred to a hundred and fifty years after their first introduction, the wooden railways appear to have been made in the following manner:—The road was prepared by being levelled, or reduced to as uniform an inclination as circumstances would allow; pieces of wood, roughly squared, about six feet long and four to eight inches square, were then laid across it at a distance of about two or three feet from each other, and upon these other pieces, carefully sawn, about six or seven inches wide and five deep, were fastened by means of pegs, in such a manner as to form two wheel-tracks about four feet apart. The road was then completed by filling the spaces between the cross-pieces (which are called *sleepers*), and under the rails, with ashes, gravel, or other road materials. *Fig.* 1 is an elevation and ground-plan of this primitive railway, *a a* being the sleepers, and *b b* the rails.

Fig. 1.

An important improvement on this construction consisted in the addition of a second set of rails, similar to the first, and spiked or pegged down to them, as shown in the elevation, *fig.* 2, in which *c* represents the upper rail. In the

Fig. 2.

former plan the removal of a rail that was broken or worn out frequently occasioned the derangement of the sleepers, and rendered them useless, from the peg-holes becoming too large. By this improvement these inconveniences were removed, as the upper rails might be repeatedly renewed without disturbing the substructure, and there was no necessity for pegging twice into the same hole. Another advantage of the change was that, by the rail being raised, a greater depth of ballast or road material might be spread over the sleepers, to protect them from the horses' feet.

The vehicles used upon these wooden railways were generally waggons, containing from two to three tons of coal, mounted upon small wheels. The wheels were provided with a flange, or projecting rim, which, by coming in contact with the side of the rail, kept the waggon in the proper direction. Each waggon was drawn by one horse.

As it was desirable that, as far as possible, the power of the horses should be equally applied in every part of the road, it became usual at an early period, at least as early as 1716, to nail thin plates of malleable iron upon the surface of the wooden rails, wherever a steep ascent or a sharp curve rendered the draught harder than usual, so that the horse might travel with a full load upon the ordinary portions of the line, and yet, by the help of the greater smoothness of an iron surface, be able to pass the difficult points without inconvenience. The circumstances in which these lines were used were such that there was almost invariably a descent towards the river or sea-shore, which, being in favour of the load conveyed, was an advantage. Where the descent would otherwise be too abrupt, it was not unusual to make an elevated staith at the river end of the railway, and shoot the coal from the waggons, by an inclined plane, at once into the hold of the ships. Sometimes also, where the inclination would prove inconvenient if distributed equally along the line, it was so arranged that the greater part of the railway was made of a convenient descent, and the remaining fall accomplished by one or more inclined planes, or *runs*, which the waggons were allowed to descend by their own gravity, the velocity being checked by a piece of wood, called a *brake* or *convoy*, being pressed forcibly upon one or both of the wheels on one side of the waggon.

It may be supposed that the saving of labour effected by means of the wooden railway was considered sufficient for the purposes to which it was applied, as it continued in use for a century and a half without any important step being taken for the introduction of a more durable material. Some *stone-ways* were constructed for similar purposes, but, though possessing many advantages, they are not so smooth as those of wood. The next material improvement was the use of cast-iron plates upon the wooden rails. It is somewhat remarkable that, notwithstanding the well known effect of iron plates in diminishing the resistance, and their frequent use as already stated, this experiment is said to have been made more in consequence of accidental circumstances than as a premeditated measure of improvement. A wooden railway was in use at the Colebrook Dale iron-works, about the year 1767, when the price of iron became very low, and it was determined, in order to keep the furnaces at work, to cast bars which might be laid down upon the wooden rails, and save expense in their repairs, and which it was proposed to take up and sell as pigs in case of a sudden rise. This plan was suggested by Mr. Reynolds, whose name is also worthy of remembrance from the circumstance of his having erected the first iron bridge set up in England, also at Colebrook Dale. These bars, or 'scantlings of iron,' as they were called, were five feet long, four inches broad, and an inch and a quarter thick, and were cast with three holes for convenience of nailing to the wooden rails. Mr. Hornblower, an ingenious mechanician, known as a rival of Watt, in describing this road, remarks on the facility with which vehicles might be turned off the track when required, owing to the absence of a guiding flange; but this is a convenience incompatible with some of the most important qualities of a railway. Various plans have been proposed for combining the smoothness of a railway with the character of a common road, and of these perhaps none is more feasible than that patented by Mr. Woodhouse, in 1803, in which, by ingenious arrangements which it is not necessary here to detail, rails of the sectional form represented by *fig.* 3, are imbedded in an ordinary pavement or road.

Fig. 3.

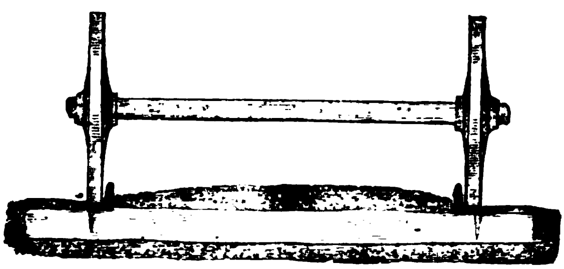
The concave form of the upper surface of the rail would tend to keep carriages in the right direction, and yet admit of their being turned out without difficulty. The ease of draught which would be attained by the adoption of such a plan may be conceived by observing the effect of the iron gutters in some of the streets of London, which closely resemble Woodhouse's rail in form, and are frequently made use of as wheel-tracks by drivers, notwithstanding the inconvenience, and even danger, arising from their being confined to one side of the vehicle.

Shortly after the experiment at Colebrook Dale, cast-iron rails with an upright flange, as shown in section in *fig.* 4, were brought into use. They were first used, it is believed, at the colliery of the Duke of Norfolk, near Sheffield, in 1776. Originally they were fixed upon cross sleepers of wood, like those used to support wooden rails.

Fig. 4.

They were cast with holes for nails, and so laid down that the flanges should either both of them be towards the middle of the track, or *vice versâ*, so that, as explained by *fig.* 5, which represents an end section of the two rails fixed to

Fig. 5.

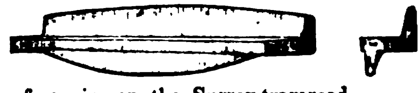


a sleeper, with a pair of wheels on them, one flange on each rail is sufficient to prevent carriages running off.

About the year 1793 blocks of stone were introduced as supports, instead of the wooden sleepers. They were, in the early railways, about a foot square, and eight or nine inches deep. One of these blocks is imbedded in the road under each joint in the rails, which are spiked down to wooden plugs inserted in the stone. As the foundation afforded by stone blocks is firmer than that of wooden sleepers, they were quickly introduced in most cases where a durable road was required.

Many ingenious improvements have been made upon the kind of railway just described, which is still extensively used in mining districts for the conveyance of coal, ironstone, &c. It is, for distinction, called the *plate*-railway or *tramroad*, and is very convenient from the facility of its construction, and the circumstance that vehicles adapted for use upon it may also, if necessary, be used off the rails. The form of the rail is however a weak one, considering the quantity of iron used, and it is such as to permit the lodgement of stones and dirt, which not only impede the motion of the carriages, but are also liable to throw them out of the track. The former of these inconveniences has been in some degree remedied by the use of a rail with an under rib, as shown in *fig.* 6, a form which was adopted to reduce

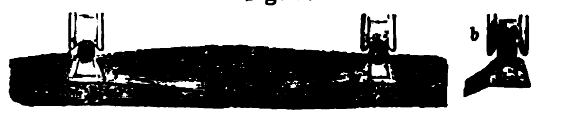
Fig. 6.



the cost of repairs on the Surrey tramroad.

The serious disadvantages of the plate-railway led to the use of *edge*-rails, which have now almost entirely superseded the previous form. The first edge-railway of any considerable extent was that completed in 1801 for the conveyance of slate from the quarries of Lord Penrhyn. Its construction is illustrated by *fig.* 7, which represents the two rails, and the form given to the tire of the wheels in order to keep them in the right course. These rails were

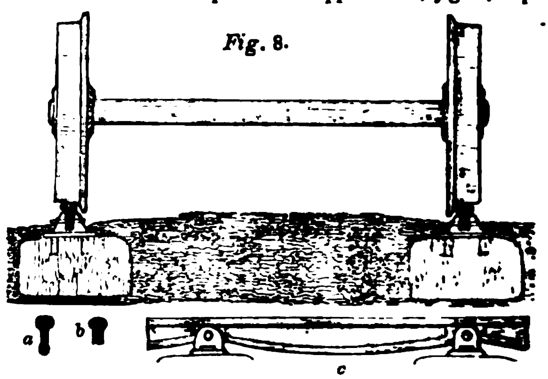
Fig. 7.



of an oval section, the longest diameter being vertical. They were four feet six inches long, and had a dovetailed block cast beneath each end, which fitted into an iron sill imbedded in the road. The wheels were formed with a grooved tire, fitting loosely on the rail. It was found however that in course of time the groove became so deepened by wear as to fit the rail tightly, and thereby produce much friction. To remedy this, Mr. Wyatt, the inventor, introduced a rail and wheel formed as shown at *b*, *fig.* 7, in which the bearing surface of the rail and the corresponding part of the wheel were flat. The rails being laid only two feet apart, the carriages were necessarily small, and the friction considerable, yet the saving of power effected was such that two horses regularly drew a train of twenty-four waggons, each containing about a ton; and *ten* horses were found sufficient to conduct a traffic which had, on a common road, required *four hundred*.

The decided advantages of edge-rails were so well appreciated by the coal-owners of Northumberland and Durham, that they were adopted extensively by them within a few years after the successful experiment at Penrhyn. The form of rail most generally adopted was even better calculated to economise the strength of the iron than that of Mr Wyatt. The following figures represent a mode of construction introduced early in the present century, and which is still used for colliery railways to a considerable extent. The rails are cast in lengths of three or four feet, and their greatest sectional dimension is in the depth. They are made of what is called a fish-bellied form, the lower edge being curved so as to give the rail greater depth in the centre than at the ends or points of support. *a*, *fig.* 8, repre-

Fig. 8.



sents the cross section of the rail in the middle, and *b* at the end. The ends are so made as to form a half-lap joint (*fig.* 9), and they fit into a suitable cavity in a cast-iron pedestal or chair, which is spiked down to the ordinary stone blocks or

Fig. 9.

wooden *sleepers*. A side view of the rail with two chairs is given at *c*, *fig.* 5, and the upper part of the figure is a section of the railway as completed, showing also the form of wheel employed. It will be readily perceived that the rounded surface of the rail renders the lodgement of extraneous matter almost impossible. The means adopted to keep the carriages upon the rails are much the same in this as in the plate-railway, but the position of the parts is reversed, the protecting flange being upon the wheel instead of the rail. By this arrangement the flange may be made much smaller than that of a tram-plate, and the friction is usually still further diminished by giving a slightly conical form to the wheel-tires, so that the flanges are but rarely brought into actual contact with the rails.

Although the principle of construction here given is that most commonly followed, the details vary so much that hardly any two railways are alike. More will be said on this subject in treating of the improved railways constructed during the last ten years, it being the object here to present an outline of the progress made in the construction of railways prior to their recent extraordinary extension. The sectional forms of edge-rails, though very various, generally bear a considerable resemblance to that here represented; and the fish-bellied profile has been selected as the most usual, although *parallel* rails, or those with an equal depth throughout from end to end, have also been extensively used. The form of the chairs or pedestals, and the method of securing the rails to them, is also very variable. In *figs.* 8 and 9 the rails are represented as having half-lap joints, the two ends being placed together between the cheeks of the chair, and fastened by a pin driven through the whole. Sometimes the ends of the rails are made square, abutting against one another in the chair, and secured by a separate pin through each rail. Since the general introduction of locomotive engines, the use of pins has been abandoned, as they have a tendency to work loose, and wedges or keys, which may be tightened when necessary, have been applied in different ways in their stead. In some cases edge-rails have been cast with a pedestal attached to one end, fitted to receive the opposite end of the adjoining rail.

One other improvement in the construction of railways must be mentioned in this hasty sketch of their early history: it is the introduction of malleable iron as a material for rails, an improvement which may perhaps be considered to have done more than any other in preparing railroads for becoming the principal highways of a commercial country. From the commencement of the use of iron railways, much inconvenience was caused by the frequent breakage of the rails, especially those of the tram-plate form. The brittleness of cast-iron, owing to its crystalline structure, rendered it necessary that the rails should be made much stronger than sufficient to bear ordinary loads, that they might be able to resist accidental strains and shocks; but although many of the earlier railways were relaid with heavier rails than were originally supposed needful, breakages were of such common occurrence as to occasion much trouble and expense. So long as the travelling was restricted to a low rate of speed, the accidents and delays thus occasioned were of minor importance, but the difficulty of guarding against them would no doubt have greatly retarded the use of railways for the conveyance of passengers, had not an adequate remedy been provided before the experiment was made. Bars of malleable iron were laid down as rails to a limited extent as early as 1808, and there were some engineers who advocated their use, notwithstanding the inconvenience arising from their unsuitable form, no machinery being then used by which they could be made economically in any other than a square or flat form. The desire to introduce a more durable rail led also to experiments on the combination of wrought and cast iron; but these and all similar contrivances were superseded in 1820 by Mr. Birkenshaw's invention of an efficient and cheap method of rolling iron bars suitable for rails and other purposes. [Iron, vol. xiii., p. 24.] The fibrous texture of wrought-iron makes it far less likely to break when subjected to concussion than cast-iron, and the sectional form used is such as to render bending improbable. It is a remarkable fact that malleable rails, when in use, do not rust to any material extent, while the same rails, if lying on the ground beside the track, rapidly oxidate and waste away. One very important advantage of malleable rails is the reduction that they effect in the number of joints, they being usually made fifteen feet long, while the brittleness of cast rails rendered it unsafe to have them more than three or four feet, the space between two points of support. Originally the long wrought rails were confined to the parallel form, but they are now, by a very ingenious adaptation of rolling machinery, made fish-bellied when that form is preferred.

The application of railways having been, down to a recent period, limited to the conveyance of minerals and merchandise, and that at a very moderate velocity, there was little that requires remark in the construction of the carriages employed upon them. They were usually four-wheeled waggons, of small dimensions compared with those used on ordinary roads, in order that the weight might be distributed over a considerable length of road. Being guided in the required direction by the flanges, it is unnecessary to attach the axles of railway carriages in such a manner as to enable them to turn, and the wheels to lock under the body, as in common vehicles; and for the same reason, combined with the greater straightness of a railway, it is unnecessary, and usually deemed unadvisable, to allow the wheels to revolve independently of the axles. The most approved plan, especially for edge-railways, is to fix the wheels firmly to the axle, and allow the axle to revolve in bearings attached to the body of the carriage. The wheels are almost invariably made of iron, those for slow traffic being cast, and others either wholly or partially made of malleable iron, in order to diminish the risk of fracture. Cast-iron wheels were found to wear very rapidly when used upon wrought edge-rails, but the application of the case-hardening process has rendered them more durable. From a very early period, railway vehicles have been fitted with an apparatus called a *brake*, consisting of a piece of wood adapted to the form of the wheel-tires, and capable of being pressed against them by levers or screws with sufficient force to impede or arrest their revolution, and consequently the progress of the carriage. Previous to the recent adaptation of railroads to rapid travelling, the use of springs was not common, either in carriages or locomotive engines.

In the infancy of railways animal power was the only means of locomotion employed to any considerable extent, but the purpose to which they were applied, that of conveying mineral produce to a place of shipment, naturally led to the application of gravity as an auxiliary, and, in some cases, as the sole source of motion. Where, in such a case, the inclination of the ground is very moderate, the slope of the road is frequently so adjusted that no greater power is required to take a loaded carriage down, than to take it up again when empty. When a declivity occurs steeper than is convenient for the ordinary power, an ingenious arrangement called a *self-acting inclined plane* is occasionally resorted to, on which a loaded carriage, or train of carriages, is allowed to run down by the force of gravity, drawing a rope, which, after passing round a wheel at the top of the incline, is conducted down the slope and attached to an empty train—the force of the descent of the loaded vehicles being sufficient to cause the empty train to run up to the top of the plane. This admirable contrivance was introduced in the latter part of the last century, and is still extensively used. Stationary steam-engines, drawing the carriages by means of ropes guided by pulleys or sheaves in the centre of the track, have been used from an early period, generally in situations where the ascent is too great to be conveniently mounted by horse-power. Locomotive or moveable steam-engines, in many different forms, have also been tried at various times since about the year 1804, although for more than twenty years after that time their powers were very imperfectly developed.

In the following notice of the steps by which the locomotive engine has been brought to its present state of comparative perfection, those points only will be dwelt upon which are peculiar to that machine as applied to railroads, referring to STEAM-ENGINE for more general information, and to STEAM-CARRIAGE for a notice of its adaptation to ordinary roads.

The possibility of applying the steam-engine to the purposes of locomotion was conceived by several of its earliest improvers, and in 1784 a plan was suggested in one of the patents of Watt; but it does not appear that either he or any other inventor carried their ideas into practice until about 1802, when Messrs. Trevithick and Vivian patented a high-pressure engine which, by its simplicity and compactness, was admirably adapted for locomotive purposes. Within a few years they built several carriages, one of which at least, was for use on a common road. In 1805 they made some interesting experiments with a machine similar to that represented by the annexed cuts, on a tramway near Merthyr Tydvil, and thereby proved the practicability of their plan. It is remarkable that notwithstanding the extreme simplicity of this machine, it possessed almost all the essential arrangements of the modern engines; and the ideas of its inventors were so complete, that subsequent engineers have had little to do beyond improving and carrying into effect the suggestions of their specification.

Fig. 10.

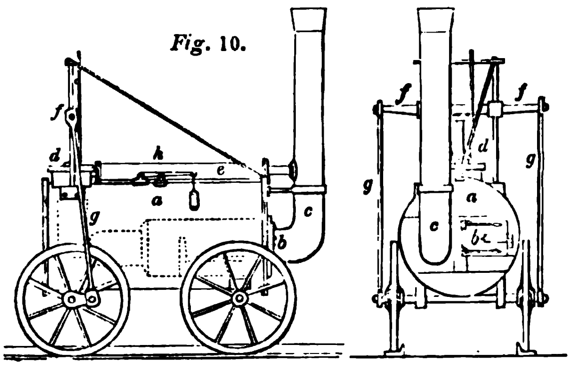


Fig. 10 is a side and end elevation of this machine, the same letters in each referring to the same parts: *a* is the boiler, which is of a cylindrical form with flat ends. The fire is contained in a large tube within, and on one side of, the boiler. One end of this is seen at *b*, and the form is indicated by dotted lines in the side view. This tube extends nearly to the opposite end of the boiler, and then, being diminished in size, it is turned round and brought out to the chimney at *c*. The fire-tube is completely surrounded by the water, by which arrangement steam is generated with great rapidity and of a high degree of elasticity. The steam-cylinder is placed vertically at *d*, being immersed nearly to the bottom of the boiler, as shown by the dotted lines. The steam is admitted alternately above and below the piston by means of a fourway-cock in a valve-box at the top of the cylinder, and the waste steam, after propelling the piston, passes by the eduction-pipe *e* into the chimney, where its emission causes a strong draft. The upper end of the piston-rod is attached to a crosshead *f*, which slides up and down on vertical guides, and from the ends of which connecting rods *g g* descend to cranks fixed on the axles of the fore-wheels, which are thus caused to revolve like the fly-wheel of a stationary engine: *h* is a safety-valve on the upper part of the boiler. The immersion of the working cylinder in the boiler is happily contrived for compactness and economy of heat, and has been frequently imitated in subsequent engines; and the admirable arrangement of throwing the waste steam into the chimney has been almost invariably followed, as it affords a blast always proportionate to the speed of the engine, and the consequent demand for the evolution of steam. This machine, when tried on the Merthyr tramway in 1805, drew a train of waggons containing ten tons of iron and a considerable number of persons at the rate of five miles per hour. Some inconvenience arose from the use of a single cylinder, because, although the impetus caused the wheels to revolve past the dead points of the crank, the motion was not regular throughout the whole revolution. A supplementary carriage followed the engine to carry a supply of fuel and water, and a small force-pump, worked by the machine itself, maintained the requisite quantity of water in the boiler.

Trevithick was aware that, although the adhesion between the engine-wheels and the rails was sufficient to ensure the progressive motion of his machine on a level or nearly level road, the wheels would slip round without advancing if the inclination were considerable or the load attached too great. He therefore in his patent proposed to remedy this by making the propelling wheels uneven by the projecting heads of bolts, cross-grooves, or fittings to railroads, where the adhesion of the plain wheels should prove insufficient. Being otherwise occupied himself, he did not proceed with his locomotive experiments, but many others entered the field, though they produced few useful contrivances that were not either used or suggested by him. An erroneous idea was for many years generally entertained, that the adhesion of plain wheels was insufficient for any practical purpose, and consequently much ingenuity was expended in contrivances for securing progressive motion by other means. One of the most successful of these experimentalists was Mr. Blenkinsop, who, in 1811, patented a locomotive engine in which the power was applied to a large cogged wheel, the teeth of which entered a rack laid down beside the ordinary rails. Blenkinsop's engine was in other respects very similar to that of Trevithick, but two cylinders and pistons were employed, working separate cranks at an angle of 90°, so that one was exerting its full force while the other passed its dead points. Engines on Mr. Blenkinsop's plan were worked for some years on a colliery line near Leeds, and drew very heavy loads at a slow rate; but the friction of the machinery was excessive, and they are consequently now disused. In 1812 Messrs. Chapman constructed engines on eight wheels, all of which were turned by the machinery in order to increase the adhesion. They also proposed to stretch a chain or rope along the railway, which should pass round a grooved wheel turned by the engine, and thereby aid the progressive motion. Shortly afterwards Mr. Brunton invented a locomotive machine, which was caused to advance by the alternate motion of two legs, thrust out from the hinder end of the engine. This singular contrivance was carried into effect, and the machine was found to have considerable power, but an accident caused the inventor to abandon it. Similar propellers have since been tried by Gordon and Gurney upon common roads.

In 1814 and 1815 engines were again tried with plain wheels, and, being found efficient, were used upon railways in the north of England. Several attempts have however been made since that time to introduce contrivances for increasing adhesion, to enable locomotive engines to ascend planes of greater inclination than they will do with smooth wheels alone.

Patents were taken out in 1816 and 1817, by George Stephenson, in connection with Messrs. Dodd and Losh, under which several locomotives were constructed and brought into operation upon colliery railways near Newcastle-upon-Tyne. The boiler in these machines resembled that of Trevithick, but the fire-tube passed completely through, instead of being turned and brought out at the back. Two vertical cylinders were used, each working a distinct axle and pair of wheels, the cranks of which were kept at the requisite angle of 90° by means of an endless chain stretched over grooved or toothed pulleys fixed on the axles; or, in the more recent engines, by connecting rods outside the wheels. A curious contrivance was introduced in them to protect the machinery from the effect of jolts caused by irregularities in the road. Four cylinders, open at the bottom to the atmosphere, and communicating at the top with the boiler, were attached to its under side, and pistons, working steam-tight in these cylinders, were fastened to the axle-bearings. By this means the pressure of the steam and water on the pistons caused the boiler and machinery to rise above the axles, and relieved them from concussions affecting the wheels. This plan ensured an equal weight bearing on each wheel, although the rails might not be level, but it has been abandoned, and steel springs employed instead. Engines of this kind seldom exceeded a speed of about five miles per hour, unless unloaded, when they occasionally ran at the rate of ten or twelve.

When the projectors of the Liverpool and Manchester railway were engaged in the design and execution of that great work in 1825 and the following years, the advantages of locomotive steam-engines were so imperfectly developed, that it was uncertain whether or not they should be adopted. The experiment of forming a railway for passengers as well as general merchandise traffic, had scarcely been tried, although the Stockton and Darlington railway, which was opened in 1825, had done more than any of its predecessors in showing the capabilities of a railway for such a use. As the Liverpool line approached completion, the directors took great pains to ascertain the best method of working it. They were soon convinced that horse-power was ineligible, as it was intended to aim at considerable velocity, and the expense of animal power when applied at a speed of eight or ten miles per hour, is very great. It was not so easy to decide on the comparative merits of stationary and locomotive engines. Various suggestions were made for the application of fixed engines at intervals of a mile or two along the line to draw trains by ropes from station to station; but it was eventually detrimental to the locomotive, and to offer a premium of 500*l.* for the best to be produced which would fulfil certain conditions, of which some were that it should not emit smoke, should draw three times its own weight at the rate of ten miles per hour, should be supported on springs, not exceed six tons weight, or four tons and a half if on only four wheels, and should not cost more than 550*l.* The trial was fixed for October, 1829, when four steam locomotives were produced, one of which was withdrawn at the commencement of the experiment. Of the other three, the *Novelty*, by Messrs. Braithwaite and Ericsson, was materially different from any previously used, being very light, and having the requisite draft produced by a blowing machine. Its performance was very promising, until an accident with the boiler put an end to the experiment. More recent attempts have been made to introduce engines of similar construction, but they have not proved successful. The *Sans Pareil*, by Mr. Hackworth, was very similar to Trevithick's engine, but had two cylinders, both working the same axle. The two pair of wheels were coupled together by connecting rods, so as to make use of the adhesion of them all. The engine attained a velocity of fifteen miles per hour with a gross load of nineteen tons, but at length gave way owing to a trifling accident. The remaining engine, the Rocket, was constructed by Robert Stephenson and Mr. Booth, of the Liverpool and Manchester railway, and succeeded in performing more than was stipulated for.

The following engraving represents a side view of the

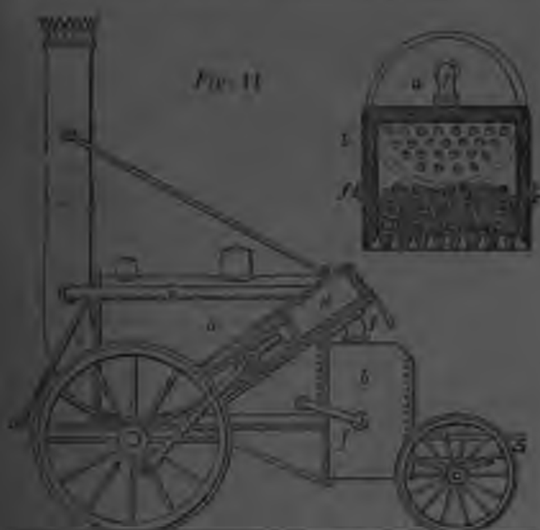

Fig. 11.

machine, with a cross section of a portion of the furnace: *a* is a cylindrical boiler with flat ends; *b* the fire-box, which is double, as indicated by the cross section, the fire being contained in the inner part, and the space of about three inches between the inner and outer casing being filled with water. Twenty-five copper tubes of three inches diameter extend longitudinally through the boiler, opening at one end into the fire-box, and at the other into the bottom of the chimney at *c*; *d* is one of the steam-cylinders, of which there were two, placed diagonally on the sides of the boiler. The piston-rods worked in guides, and by means of connecting rods transferred the motion of the pistons in a very simple and effective manner to the large wheels. It was arranged as usual that one piston was in the middle of its stroke while the other was at the end of the cylinder and consequently powerless. The waste steam passed from the cylinders along the pipe *e* to the chimney, in order to produce draft. *f f* are pipes connecting the water in the casing of the fire-box with that in the boiler.

The use of several tubes of small diameter instead of one large flue through the boiler, is the most important peculiarity of this machine, as, owing to the great extent of surface of heated metal thus placed in contact with the water, steam was produced with extraordinary rapidity. This plan, which was suggested by Mr. Booth, has since been carried to a great extent, by reducing the diameter and increasing the number of the tubes. The inclined position of the steam-cylinders caused the motion of the machinery to interfere less with the play of the springs than if they were placed vertically, but their situation had the disadvantage of exposing them to the cold air, by which the power of the steam is diminished, an inconvenience avoided in most subsequent engines by placing them horizontally in a casing under the chimney. The nuisance of smoke was prevented by the employment of coke as fuel.

The Rocket, with a gross load of seventeen tons, averaged a speed of fourteen miles per hour; but under some circumstances it attained double that velocity. Subsequent engines built by Mr. Stephenson were of much greater power, but, imperfect as the early attempts were, they proved, notwithstanding the incredulity of many, and even of some scientific men, the possibility of obtaining, by locomotive engines upon improved railways, a speed of travelling far beyond anything that can be effected by horses. Of the importance of this improvement in the means of intercourse, it is impossible, after the lapse of only ten years, to form an adequate idea; but the fact that since it was brought into operation a sum exceeding 60,000,000*l.* has been devoted to the construction of railways in this kingdom alone, may indicate in some degree the extent of the changes which it has been the means of introducing.

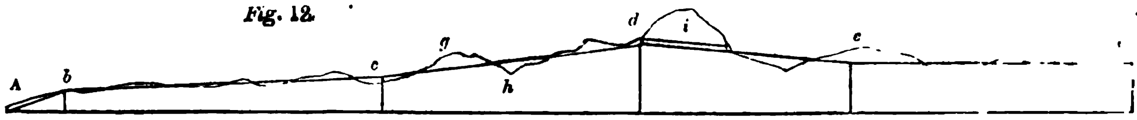
Having noticed the most important inventions and experiments connected with railways and locomotive machinery down to the time of their application on an extended scale upon the Liverpool and Manchester railway, it may be well to treat of subsequent improvements as they will come under notice in a sketch of the various operations of designing, constructing, and working a railway for general traffic.

Designing a Line of Railway.—It is not intended here to enter into a disquisition on the important economical questions which should be considered in marking out the main lines of communication in a country, and which, with some variations, are applicable alike to railways, ordinary roads, and canals. It is the opinion of many persons that a system of railroads should be laid out by the government of a country, whether they are actually formed by the state or by private individuals. Arguments in support of such a view have been drawn from the want of unity of plan which is evident in the railways of England, they having in most cases been designed in short lines from one important town to another, without due regard to combination of plan. The commissioners appointed to report on a system of railways for Ireland have considered this subject very ably, and endeavoured, in their proposed lines, to avoid the errors consequent on the limited views of private speculators. Most of the continental railways have been laid out more under government control than those of England, but there are not at present sufficient data from experience to allow of a fair comparison between the working of the two systems. In considering this point it should not be forgotten that, however desirable a comprehensive plan may be in a country yet to be supplied with railways, experience in cases most analogous leaves but little reason for supposing that the railway system would have made the sudden advances that it has, unless under the stimulating though by no means unexceptionable agency of private speculation and commercial enterprise.

When the termini and general course of a line of railway are determined on, there remain many points to be considered in selecting the precise direction which it shall take. It is necessary carefully to examine the country to be passed over,—its elevations and depressions—its rivers, canals, roads, and all other streams of water or means of communication that have to be crossed, or in any way interfered with—and its geological structure; any of which may occasionally render a deviation from the direct course advisable.

It is evident that, as a general rule, a perfectly straight and level line is to be preferred, when the termini are of equal elevation; or a uniform slope when one is higher than the other. An attempt has indeed been made to prove that a railway formed in a series of undulations would be preferable to one perfectly level, because the power of gravity might be used to aid in the descents, and that of acquired momentum in the ascents, thereby reducing the amount of artificial power required for moving carriages upon the road. This theory excited much discussion a few years since, but the general opinion of engineers was not favourable to it. There are however some circumstances under which advantage may be taken of the powers of gravity and momentum, without the serious inconveniences which would attend the use of an undulating railway like that suggested by the author of this theory. But, desirable as a perfect level or uniform slope may be, it rarely happens that either can be attained for any great distance without involving such a deviation from the natural surface of the ground as would be very inconvenient. The engineer therefore so adjusts his inclinations or gradients as to make the nearest practicable approach to a level, avoiding if possible any loss of power from undulations of surface, by making all the inclinations on one side of the summit, or highest point to be passed over, rise towards it, and all on the opposite side descend from it. In order to the due adjustment of the gradients, a section or profile of the line of country is prepared, in which the elevations and depressions are drawn to a much larger scale than the horizontal distances, in order that, by being made disproportionately steep, they may be more readily recognised by the eye. *Fig.* 12 is a section of an imaginary line, resembling, except in its small size, those prepared for parliamentary inspection. The horizontal line at the bottom is given as a datum for measuring the elevations from, and is made to have reference to some fixed point near one of the termini. This section may be supposed to represent the line of a railway between a seaport town at A, and an inland town at F: the undulating line representing the natural surface of the ground; the straight lines from point to point, the intended surface of the railroad; and the vertical lines marking the changes of inclination. Owing to the intervening high ground, a uniform slope from A to

Fig. 12.



F is impracticable, but a line with very moderate inclinations is obtained by tunnelling through the ridge at *i*, excavating the minor elevations, and filling up the hollows. If a road were made on the natural surface of the ground, a carriage passing along it would, after mounting to the elevation *g*, have to descend to *h*, and immediately remount to the top of *i*, thereby having twice to ascend an elevation equal to the difference between *g* and *h*, involving a considerable waste of power, which would be caused more or less by every undulation passed. But in a road constructed on the level of the proposed railway, not only would part of the elevation of *i* be avoided by the tunnel, but that which remains would have to be ascended but once, as every part between A and *d*, the summit of the road, rises towards it, though in different degrees; and in like manner the whole distance between *d* and *e* inclines downward, while the remaining part, from *e* to F, is perfectly level.

Owing to the short interval which has elapsed since the commencement of railway operations on a large scale, many theoretical points respecting them yet remain unsettled. Even the amount of retarding effect caused by passing over a given elevation is calculated variously by different engineers. On an ordinary road the resistance arising from friction and irregularity of surface is so great that the effect of gravity is scarcely perceptible on a moderate inclination; but on a railway the friction and road-resistance are reduced to so small an amount, that gravity, which remains the same, becomes a material part of the total resistance, even where the inclination of the road is so slight as to be almost imperceptible to the eye. A theory held by many engineers is, that an elevation of twenty feet requires an exertion of power equal to that on a mile of level railway; so that the same power which would move a given load over one mile of railway rising 1 in 264, or twenty feet in the whole, would move the same load over two miles of level road. The practical importance of this question is very great, because a correct understanding of it is essential to show how far it may be advisable to deviate from a direct course in order to avoid a given elevation. Supposing, for instance, that a railway is required between two points twenty miles apart, and that a straight course may be obtained by passing over an elevation of 100 feet, it may be preferable to increase the length to twenty-four miles, if by so doing a level can be obtained; because the elevation of 100 feet will require as great an expenditure of power as five miles of horizontal railway.

Another question on which there exists much difference of opinion, is the degree of steepness that may be allowed in any of the inclined planes without injuriously affecting the working expenses. It is often necessary to conduct a railway over a considerable elevation, but engineers differ as to the best arrangement of the unavoidable inclinations. Some prefer distributing the rise and fall as equally as possible throughout the whole line, while others consider it best to concentrate them in a few steep planes, in ascending which additional power is used, and making the rest of the line comparatively level. The Liverpool and Manchester railway may be cited as an instance of the latter mode, the main line having no gradient exceeding 1 in 849, with the exception of two inclined planes of about a mile and a half each, inclining 1 in 89 and 1 in 96, near Rainhill; at which it is usual to assist the trains by an additional locomotive engine. The Great Western railway also, in a length of 117¼ miles, has no steeper gradient than six feet six inches per mile, or about 1 in 812; but has two inclined planes of 1 in 100 for a length of one and a half and two and a half miles respectively. The London and Birmingham railway is an example of the former system, its ordinary gradient being 1 in 330, or sixteen feet per mile, which is nowhere exceeded except on the extension from Camden Town to Euston Square, which was intended for working by stationary engines. The characteristic or ordinary gradient on the Southampton, Brighton, South-Eastern, and many other lines, is 1 in 264, or twenty feet per mile.

A certain degree of similarity in the gradients is essential to the economical working of a railway by inanimate power which cannot be so conveniently urged as that of horses to a temporary exertion to overcome a short but steep ascent. If therefore any inclination occur so steep that the ordinary power cannot ascend it by a reduction of speed, it must either be surmounted by the aid of auxiliary power, or the engine must run over other parts of the road with less than a maximum load, and consequently at unnecessary expense. So long as this inconvenience is avoided, it is the opinion of some scientific men that the degree of inclination is of little consequence on a railway with an equal traffic in both directions, because the assistance of gravity in the descent being set against the additional resistance in ascending, brings the total amount of power required in traversing the line *in both directions* to nearly the same as would be needed were the road a perfect level.

Some highly interesting experiments have been recently made on this and other points of railway economy, under the superintendence of Dr. Lardner, of which the following seems to indicate that this compensating effect takes place on inclinations of much greater steepness than has been generally supposed. Great caution is necessary in forming calculations on such a subject from single experiments, however carefully conducted, but the results are certainly such as to justify serious inquiry. In July, 1839, the Hecla engine, with twelve carriages, making a gross weight, including the engine, of eighty tons, was run from Liverpool to Birmingham and back in the same day; by which means the same train, under as nearly as possible the same circumstances, had to ascend and descend every plane on the line, a length of about ninety-five miles. The time of passing each quarter-mile was carefully observed, so as to obtain the speed on every portion of the road. The following table, extracted from the seventh edition of Lardner on the Steam-Engine, gives the result of observations on gradients varying from level to 1 in 177, or nearly thirty feet per mile:—

Gradient. One in	Speed in ascending. Miles per hour.	Speed in descending. Miles per hour.	Mean speed. Miles per hour.
177	22·25	41·32	31·78
265	24·87	39·13	32·00
330	25·26	37·07	31·16
400	26·87	36·75	31·81
532	27·35	34·30	30·82
590	27·37	33·16	30·21
650	29·03	32·58	30·80
Level	——	——	30·93

From this table it appears that although the plane of 1 to 211 diminished the speed from near thirty-one miles per hour, the velocity on a level, to little more than twenty-two miles, in the ascent, the deficiency was fully compensated by the increased rapidity in the descent. The trifling differences in the mean speed on the different gradients may probably be attributed to accidental circumstances; but, small as it is, it is rather in favour of the steepest inclinations than otherwise. The result fairly indicates a most remarkable and valuable fact, namely, that a line of railway with gradients of from twenty to thirty feet per mile may be worked in both directions by the same expenditure of power as a dead level; and this fact, if substantiated by more extended experiment, proves that many millions may be saved in the formation of future railways by being content with steeper inclinations than have hitherto been admitted by most engineers to be advisable. The whole of the compensating effect here produced is not to be attributed to the agency of gravity and momentum; a part, and perhaps a very considerable part of it, being due to the diminished resistance of the air to the passing of the train on ascents, owing to its reduced velocity. The nature and extent of atmospheric resistance to railway trains is a point on which so little is known, and opinions are so conflicting, that the extent of its influence in the experiment alluded to cannot be stated with certainty, but it is probably considerable, as the result is very different from that which might by calculation have been expected from the mere effect of gravity and friction. The resistance of the air being almost imperceptible in the case of common roads, owing to the great friction and moderate velocity, has frequently been considered too trifling to become an element in calculations on railway transit, and hence arises much of the error that has hitherto prevailed respecting inclined planes. For further information on this subject see RESISTANCE.

Dr. Lardner thinks that his experiments indicate the gradient by which the gross resistance is doubled to be nearer 1 in 94 than 1 in 260, which he, in common with many others, had formerly considered the limit, though 1 in 264 has been mentioned above as being a more moderate and perhaps more usual calculation.

Curves on a main line of railway being, in consequence of the peculiar construction of the carriages and the speed at which they travel, very objectionable, a judicious engineer so adjusts his line as to avoid them when possible, and to make those which are inevitable of as large a radius as circumstances will admit. Curves of less than a mile radius are considered unadvisable for places where great velocity is required, although many of only half a mile radius are in use, the rails being so laid as to counteract the danger that might arise from the centrifugal force of trains passing over them, as explained hereafter. At stations and depôts, where the trains always move slowly, the radii may be much shorter without inconvenience.

It is essential to the public safety that a railway should not be allowed to cross any much frequented road on the same level. When the Liverpool and Manchester line was projected, as the rate of travelling was not expected to exceed ten miles per hour, no danger was anticipated from such intersections, which are called *surface-crossings*; and accordingly several were allowed; but their inconvenience and danger have caused some of them to be altered, the road being continued under or over the railway by means of a bridge. In recent railway Acts it is enacted that no turnpike-road or highway shall be crossed on the same level; a rule to which exceptions are very rarely allowed; and if they are, gates must be erected to enclose the railway, and attendants stationed to open them when necessary for the passage of vehicles across it. These gates should be so hung as to completely close the railway when the road is open, and *vice versâ*. In a few instances two railways have been allowed to intersect each other on the same level, but this highly dangerous arrangement is now very rarely permitted. Where a single road is crossed, it may not be necessary to regard it much in selecting the level for the railway, as such road may be made to slope gradually to the requisite level for passing under or over it; but in approaching towns, where many communications are interfered with, it is essential that the railway level be made higher or lower than the ordinary surface, in order to avoid them. At Liverpool this is effected by tunnels under the town; at the London end of the Birmingham railway by an open cutting; and at Manchester, Birmingham, and many other places, by an embankment or viaduct. The Greenwich railway, extending over a metropolitan district the whole of its length, is entirely on a viaduct, and that from London to Blackwall, a similar line, principally so.

Railways, being usually constructed on as low a level as possible, frequently intersect the course of rivers and canals, rendering numerous and expensive bridges necessary. Where the course of the streams thus crossed is sinuous, expense may sometimes be reduced by making a new channel for the river, such a cut often being the means of avoiding the erection of two bridges, as in the instance of the Manchester and Leeds railway in the valley of the Calder.

Obtaining an Act of Parliament.—Railways being in this country constructed by associations of private individuals, with a view to their own pecuniary advantage, as well as to public convenience, it is necessary that, on the one hand, legislative restrictions should be imposed, to protect the interests of those who may directly or indirectly be affected by the formation of the railway; and, on the other, that the promoters of the scheme should be invested with considerable powers, to enable them to carry it into effect. Lands, buildings, rivers, canals, roads, &c. have to be intersected and otherwise interfered with; and while justice requires that no unnecessary injury should be inflicted on their owners or the parties using them, and that every unavoidable interference should be amply paid for, it is also necessary to prevent a plan likely to be of great public benefit from being defeated by objections arising from prejudice or private interest.

Owing to the number of crude and ill-judged speculations of 1835, 6, and 7, which proved the necessity of imposing various restrictions on the facility of obtaining parliamentary powers, new standing orders were introduced with a hope of more effectually insuring the public against being misled by over sanguine projectors. An opinion is entertained by many, that these regulations are now too stringent; and the very limited number of new undertakings sanctioned by parliament since they came into operation, though partly to be accounted for by other circumstances, leaves some reason to question whether, in the attempt to restrain improper speculation, legitimate enterprise has not been injuriously shackled.

Under the existing standing orders of parliament respecting railway bills, it is required that plans and sections of a proposed line, on a scale of four inches to a mile, shall be deposited with the clerks of the peace for the several counties through which it is proposed to carry the railway, on or before the first day of March, and in the Private Bill Office, &c., on or before the first day of April in the year preceding that in which an application is made to parliament for an Act. The plans are accompanied by a book of reference, showing the owner, lessee, and occupier of every house or piece of land liable to be passed through or otherwise interfered with. The sections indicate not only the length and inclination of each gradient, but also the actual elevation of numerous points above the base line used as a datum, and the elevation and proposed mode of crossing every stream or road intersected by the railway. Portions of these plans and books are also deposited for reference with the clerks of parishes through which the line runs, if in England, or if in Scotland or Ireland, with other specified officers; and notice is given of the intention to apply for an act of parliament, both publicly by London and county newspapers, and privately by notices to owners and occupiers of property affected. The former of these notices being given in February and March, a whole year is allowed for interested parties to consider the scheme and make preparations for advocating or opposing it in parliament. Before 1837, notices given and plans deposited in the month of November before the meeting of parliament, were considered sufficient. The shorter period was far more favourable to railway companies than the present, because the surveys are frequently made in the autumn, immediately after the removal of the crops, and the plans might then be prepared in time for obtaining an Act in the ensuing year; or, if a company were defeated in parliament one session, they might amend their line to obviate the objections brought against it, and be prepared for the next session. Now, a line surveyed in the autumn of 1840, must have the plans deposited in 1841, and the application must be made to parliament in 1842, so that it could scarcely be commenced till 1843; and a company failing in one session, must wait till the next but one, or proceed with plans deposited before a parliamentary opposition had shown what objections would be brought forward, or how they might be obviated. Owing to the long time between the plans being deposited and the Act being applied for, it frequently happens that they are deposited before a company is formed, with the intention of using them, if circumstances are favourable as the time approaches. The number thus provisionally deposited may be supposed from the fact that plans of thirty-six new lines were deposited for the session of 1840, none of which were brought forward. If the company intend to proceed with their project, the shareholders are required by the standing orders to subscribe to a contract, binding themselves, their heirs, executors, &c. to pay up the whole amount of the shares they take, when called upon to do so. This subscription contract must be signed between the time of making an application for an Act and the close of the session next preceding. They must also, according to the orders of the Commons, deposit a sum of ten per cent. on the proposed capital, in government securities. If the preliminaries have been duly attended to, a bill is brought in for incorporating the company and investing it with the necessary powers. After being read a second time, it is examined in a committee, which, if the bill be opposed, is composed of those members who represent the districts affected by the measure, and of a quorum, generally not less than three, of selected members having no interest in the question either personally or for their constituents. The committee report on the length, gradients, curves, and other peculiarities of the line; on the estimated outlay, and its apparent sufficiency; the traffic expected; the sufficiency or insufficiency of the existing means of communication for agricultural, commercial, manufacturing, or other purposes; and the probability of remuneration to the shareholders. They also receive lists of the owners, lessees, and occupiers of the land, &c. that may be required, showing whether they are assenting, dissenting, or neutral parties to the bill; and examine the list of shareholders, to guard against the introduction of irresponsible persons. Petitions presented respecting the bill are referred to the committee, who frequently insert clauses for the special protection of the petitioners. If there be any competing line of railway existing, in progress, or in contemplation; or if any parties oppose the bill on the ground of the line being unnecessary or injurious; a very expensive and tedious examination of witnesses is the result. Counsel are engaged on both sides, and evidence is heard sometimes on almost every point to be embraced in the report. The expense attending these contests is a strong argument against the existing system, which is considered defective also in many other points. After leaving the committee, the progress of a railway bill seldom excites much interest or attention. Unopposed bills are for the future to be re-referred only to the chairman of ways and means, and the two members in charge of the bill.

The preamble of a railway Act recites that it is expedient to construct the railway therein described, and that certain persons, whose names are given, are willing and desirous to make it at their own costs and charges. The Act forms them into a corporate body, invested with powers to take and make compensation for the necessary property, and to construct the railway. As the surveys are often made hastily and under great disadvantages, a deviation from the line laid down in the plan to the extent of a hundred yards is allowed for the sake of improving the line, such deviation being limited to ten yards in towns, and not being allowed to extend into any lands not included in the plan and book of reference. Powers are also given for altering, to a very limited extent, the levels and gradients defined on the parliamentary section. The company is allowed to raise a certain sum, sufficient to cover the estimated expense, in shares among themselves; and also, if necessary, to borrow a further sum, not exceeding one-third of their capital, as soon as one-half of it is paid up. Such additional sums may be raised in new shares, at the option of the company. Clauses are inserted to protect the rights of individuals, to specify the dimensions of road, canal, and river bridges, and the slope to be given to roads where they are altered. A board of directors, selected from the principal shareholders, and generally from twelve to twenty-four in number, is appointed to conduct the affairs of the company, to make calls for the capital as required, &c.; and provisions are inserted for a change in this body by a certain number being balloted out periodically, and the vacancies filled up by the proprietors at their annual or half-yearly meetings. Powers are given to the company to take certain specified tolls, to carry passengers and goods, and for many other purposes. To provide for the possible abandonment of the scheme, it is stipulated that the compulsory powers for taking land shall cease after the lapse of two or three years, and that, if the works are not completed within a period of, in most instances, seven years, or, having been completed, are not used for three years, the land shall revert to the owners of adjoining property.

Owing to the numerous subjects embraced, a railway Act frequently fills from one to two hundred folio pages. It has been suggested that much expense and trouble might be saved by the passing of a General Railway Act, embracing those points common to all, so that an ordinary Act need contain only what is peculiar to the individual line. In many cases Amendment Acts are required by a railway company to enable them to raise additional money, or to execute extensions or alterations of the original line; but these do not require any detailed notice. As instances of the expense attendant on the present mode of obtaining railway Acts, when opposed, it may be stated that the London and Birmingham Railway Company spent more than 72,000*l*. in procuring theirs, and the Great Western upwards of 88,000*l*. The London and Brighton is perhaps the most expensive contest of the kind that has taken place, four or five companies having engaged in it for two successive sessions. When in committee, the expense of counsel and witnesses in the latter case is stated to have amounted to 1000*l*. daily, for about fifty days.

The act of parliament being obtained, the land required for the railway is definitely set out and purchased. Power is usually given to take a width of twenty-two yards, exclusive of what is necessary for the sloping sides of cuttings and embankments, but this width is seldom required. When moderate compensation is demanded for the land taken and the injury caused by the severance of estates, the removal of buildings, and other circumstances, the company have no need to put their compulsory powers in force. But where, as too often has been the case, exorbitant claims are made, recourse is had to a jury. In most cases where this alternative has been resorted to, the sum awarded has been much under that claimed,—frequently less than a quarter, and in one recent case only about a fiftieth part of it. The item of land is one of the causes of that excess of cost over estimates which has been so severely animadverted on, and another is the expense of extra bridges claimed by landowners as communications between severed lands, the trifling utility of which is indicated by the circumstance that, after extorting an agreement to build them, persons have often accepted one-half of their cost, in lieu of having them erected.

Formation of the Road.—Under this head is included the execution of those works necessary for the construction of a road (independent of the rails and finishing works), of the required level and width. These works consist of tunneling, excavation, embankment, and masonry for bridges, viaducts, and other erections. They are commonly divided into convenient portions, and let to contractors under agreement to complete them at a stipulated price and within a specified time. It is usual to commence those works which take the longest time first, that the capital expended on others may not lie idle till they are completed.

Tunnels are, in general, the most formidable works, and the time and expense of forming them can be least accurately calculated, because unforeseen circumstances often arise to retard their progress. Trials of the nature of the ground are made by boring, but these may indicate favourable strata, while, as in the well-known instance of the Kilsby tunnel, difficulties may exist requiring great energy and skill, and an enormous outlay to overcome. Being objectionable also on other accounts, tunnels are avoided as much as possible in the more recently designed railways. For the mode of constructing them, see TUNNEL.

Cuttings or excavations of great depth and extent are of frequent occurrence where the railway passes through high ground, but not at such a depth from the surface as to require a tunnel. The depth of cuttings is frequently from fifty to seventy feet and occasionally even greater. One very extensive excavation through the Cowran Hills, on the Newcastle and Carlisle railway, is as much as a hundred feet deep. The degree of slope necessary in the sides of cuttings varies greatly in different soils. Rock will stand when nearly vertical; chalk varies from nearly vertical to a slope of one horizontal to one vertical, or an angle of 45°;

gravel stands usually at one and a half to one; London clay from one to one to three to one, having in some instances stood at the former and slipped at the latter slope. Some materials are insecure at even a greater slope; blue shale having, according to Lecount, slipped at an inclination of four horizontal to one perpendicular. The unexpected slipping of the slopes sometimes occasions much trouble and expense. A case lately occurred in the north of England in which a cutting to be formed in the side of a hill was estimated to require the removal of about 50,000 cubic yards of earth. It turned out, however, that the soft earth was held up by a seam of shale, which was no sooner cut through than a mass of earth slipped down into the line of the railway, of such magnitude as to require the removal of about 300,000 cubic yards. The great cutting at Blisworth, on the London and Birmingham railway, affords an example of a convenient and economical method of passing through earth in which strata of rock occur. The railway is at a depth of fifty or sixty feet, the upper portion of which is rock, and the lower consists of a less solid material. Instead of making an excavation of the slope required by the lower strata, which would have rendered the removal of the superincumbent rock indispensable, the sides were made nearly vertical, and the rock was supported by an under-setting of masonry. The great breadth of ground occupied by the slopes of cuttings is a serious objection when they are in the vicinity of towns or pass through valuable property, in which cases the sides may be made nearly vertical, and supported by retaining walls, so curved as to enable them to sustain the pressure of the earth. The extension of the Birmingham railway to the Euston station affords a very bold and handsome example of this kind of work. In designing the works of a railway, the amount of excavation and embankment should be balanced as nearly as possible, so as to avoid the necessity of depositing earth from cuttings in spoil-banks, or having to purchase additional land to supply material for the embankments. Attention to this point will sometimes decide which is most expedient, a short tunnel or an open cutting.

Embankments are the artificial ridges of earth formed to support the railway on a higher level than the natural surface of the ground. Their dimensions are often fully commensurate with those of cuttings, from which their materials are mostly procured. In the ordinary mode of proceeding, an embankment is formed simultaneously with a cutting, the earth-waggons proceeding filled from the excavation along a temporary railway to the embankment, where they are tipped up to discharge their contents. A heavy embankment often forms the key, as it were, to the time of completing a railway. Tunnelling and excavation may be proceeded with at many different points, but an embankment, under ordinary circumstances, can be carried on only at the ends, and the number of men employed there is restricted by the limited space. Time is occasionally saved by the erection of a temporary wooden stage at the end of the embankment, affording the means of tipping a greater number of waggons at one time than can be done without it. Where the excavations do not afford sufficient material, embankments are partially formed of earth dug from trenches along their sides, and thrown up into the centre. This is called side-cutting, and, being an expensive proceeding, should be resorted to as little as possible. An important element in the cost of embankments is the length of the lead, or distance to be traversed by the earth-waggons between the points of filling and emptying. The sides of embankments, like those of cuttings, require a considerable slope, especially when the material is of an unfavourable nature. The earth should be deposited in layers of two or three feet thick, slightly concave on the upper surface, and, if time permit, it is well to allow one layer to settle before another is spread over it. The subsidence of newly-made embankments is a source of great expense, and sometimes of danger. It is usual to lay the rails in such a manner as to diminish the risk of accident from this cause, and to travel slowly over parts where a tendency to slip is observable, especially in wet weather, yet casualties will sometimes occur until these great earthworks are thoroughly consolidated by time. Allowance should be made for subsidence by making the embankments rather higher than they are intended to be finally. Great difficulties are experienced in embanking across marshy or boggy soils, which frequently sink under the weight of the earth deposited, the ground bulging up at the sides in consequence. Judicious drainage may do much in such cases, and the insertion of a frame-work of timber to bind the earth together and thereby check the unequal settlement of the embankment, has been tried with apparent success by Mr. Braithwaite on the Eastern Counties railway. To prevent carriages which escape from the rails falling over the sides of an embankment, mounds of earth are sometimes raised along them. The embankments raised across Chat Moss on the line of the Liverpool and Manchester railway, and similar places have excited much interest. The difficulties arising from the yielding nature of the material are greatly obviated by drainage, as, when dry, the moss itself becomes a fit substance for embanking, and stands well at a slope of less than 45°. The railway is sustained on part of Chat Moss by a platform of timber and hurdles, covered with earth and broken stone, and floating, as it were, on the spongy substratum. A peculiar kind of embankment required in hilly districts and along coasts consists of a road on the side of a steep elevation, one side being supported by a sustaining or revêtement wall. An important work of this kind is being executed along the face of part of the Dover Cliffs, for the South-Eastern railway, in which the revêtement wall is exposed to the sea. Similar constructions have been introduced on the Dublin and Kingstown railway, where there is also a remarkable embankment across the strand at Blackrock, that, at high-water, has the appearance of a mole stretching into the sea, which is allowed to pass through it by culverts. On the Preston and Wyre railway is an extensive embankment in a similar situation, but, when completed, it is intended to exclude the sea. Though yet unfinished, carriages are enabled to pass along by the rails being temporarily supported on piling. On the Stockton and Hartlepool line a sea-embankment of clay has been recently completed, the side being puddled and formed into such a curve as to bear the dashing of the waves without injury. Retaining walls are occasionally used to diminish the space occupied by embankments, as before mentioned in the case of cuttings. The Dublin and Kingstown railway commences in this manner, arches being introduced at the intersection of streets and roads.

The earth-works on most of the great lines of railway in England are very extensive, in many cases averaging from 100,000 to 150,000 cubic yards per mile. On the London and Birmingham line alone the quantity of earth and stone removed was about 16,000,000 cubic yards, which, if formed into a belt three feet wide and one high, would more than encompass the earth at the equator! When completed, it is advisable to sow the slopes of cuttings and embankments with grass-seed, as their appearance is thereby improved, while the roots give cohesion to the surface, and render it less likely to be affected by weather.

The amount of masonry and brickwork required in the various erections of a railway is very great. The lining of tunnels, where the ground penetrated is of such a nature as to require support, forms a peculiar kind of work. Arching of almost every kind is more or less required in viaducts, bridges, culverts, and drains; and simpler work in the retaining walls, station buildings, and other necessary erections. Viaducts of great magnitude are often executed for the purpose of crossing valleys at an elevation greater than could be conveniently obtained by embankment, and also for entering or passing through towns. They are usually of stone or brick, but sometimes of wood or iron. [VIADUCT.]

Bridges are required occasionally for crossing rivers, and very frequently at the intersection of roads, and as communications between severed property. From a statement by Lecount, in the 'Encyclopædia Britannica,' it appears that, taking the mean of nearly a hundred railways, the number of bridges averages about two and a quarter per mile. Besides ordinary arches of brick and stone, bridges consisting of cast-iron girders laid from one abutment to the other, and supporting a platform of flag-stones, iron plates, or planks of wood, are very common. When the railway itself passes over such a bridge, six ribs are used, the distances of which are so adjusted that four of them sustain the rails and the other two the parapets, leaving nothing necessary between the ribs or girders, except a flooring of iron plates. By this arrangement great strength is ensured, and the depth or thickness of the bridge is reduced to a minimum, no ballast or road material being necessary. Wooden bridges of similar character are occasionally used.

A remarkable circumstance in the appearance of railway works is the frequent occurrence of skew-bridges. They are introduced when the railway intersects any existing communication at an oblique angle. Such arches were built before the introduction of railways called them into general use, but as, in an ordinary road or a canal, a deviation from the straight line is of little consequence, it was seldom thought necessary to apply them, and was customary to build the arch of the ordinary form, on the square, and accommodate the direction of the road or canal to it by curved approaches. But as on a railway straightness is of great importance, it frequently becomes necessary, in crossing other roads, to adopt a skew-bridge, in which the communications over and under the bridge form unequal angles with each other. For an account of the construction of these ingenious works, see Skew Bridge.

When the various works described are completed, with the requisite drains and fences (which are highly important), the road is ready for receiving those finishing works which entitle it to the distinctive name of *railroad*. The level of the earth-works, when completed, is called the *formation-level*, and is usually about two feet below the intended surface of the rails. The width of this surface is about thirty feet, exclusive of the drains and fences, and it is made a few inches higher in the middle than at the sides, in order to throw off water.

Ballasting and Laying the Permanent Way.—In order to obtain a firm dry foundation for the blocks or sleepers to which the permanent rails (so called to distinguish them from the slight temporary tracks laid down during the progress of the work), are fastened, a layer or stratum of broken stone, technically called *ballast*, is spread over the road for a thickness of a foot or more, varying according to the construction adopted and other circumstances. After the rails are laid down, similar materials are used to fill in the spaces between the blocks and sleepers. The broken stone should be so small that any piece would pass through a ring two inches and a half diameter. Other substances are occasionally used, especially for the upper part of the ballast, as gravel, river-sand, and burnt clay. In some situations, with good ballast, no surface drains are necessary; but drains consisting of a brick channel along the middle of the line, with small cross drains at intervals towards each side alternately, are often required.

The great variety of opinions as to the best form and manner of fixing the rails, renders it impossible, in the limited space which can here be devoted to the subject, to do more than select a few examples of the plans principally used. The most important question involved in these differences is that of the intermediate or continuous support of the rails. The most common method of fixing them is to fit them into iron chairs, which are spiked down to blocks of stone imbedded in the ballasting. This plan, although it appears by experiment to afford the firmest foundation, has several disadvantages. The points of support, being isolated from one another, are liable to be deranged by any subsidence in the ground, as well as by the constant vibration consequent upon the rapid passage of heavy trains, and the small but irresistibly powerful action of temperature in causing the expansion and contraction of the rails.

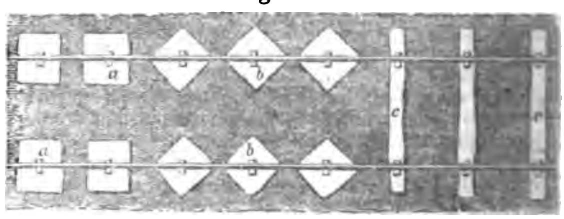
The former of these inconveniences is in some degree obviated by substituting cross sleepers of wood (like those described as being used in the early railways), for the stone blocks upon such parts of the line as are likely to sink. The two rails being, in this case, attached to the same sleeper, are not liable to be thrown out of gauge, or, in other words, to lose their parallelism, although the unequal sinking of the sleeper may cause one rail to become lower than the other. This application of wooden supports has been in most cases considered a temporary one, it being intended to lay stone blocks in their stead so soon as the ground became sufficiently firm; but as it appears from experience, both in this country and in America (where, owing to the abundance of timber and the high price of labour, wood has been much more extensively applied to railways than in this country), that the motion of carriages on those parts of a line supported by wood is smoother and quieter than on others, some engineers consider that the plan of construction upon cross-sleepers is preferable to that upon stone blocks.

In both of these modes of supporting the rail, it is sustained only at intervals of three or four feet, the intervening portion acting as a bridge, which, though very rigid, yields in a slight degree when carriages, and particularly the heavy locomotive engines, pass over it. The surface of the rail is thus converted into a series of minute undulations, the effect of which is to increase the resistance. It has been thought that these undulations were of little consequence, the gain in descending being a counterbalance to the retardation of the ascent; but Professor Barlow, in reporting on experiments made by him in 1835, for the London and Birmingham Railway Company, expresses an opinion that 'the advantage of the descent is, owing to the velocity and the shortness of the inclined plane, scarcely appreciable, and that the result of the deflection will be equivalent to the carriage being carried up a plane of half the whole length, the other half being horizontal.'

These and some other considerations have led to the adoption of a continuous support to the rail, which has been effected in several different ways, and with various success. Intermediate supports, being the most extensively employed, will be first noticed, and stone blocks, according to general opinion, claim the precedence among them.

The blocks used upon recently constructed railways are about two feet square and one thick, though much smaller ones were considered sufficient before the use of locomotive engines became general. They are roughly squared, but have so much of the surface as is to receive the chair accurately flattened. The chairs are usually fastened down by two or three iron spikes, to receive which holes are made in the stone, and filled with wooden plugs. The plugs should always be bored to receive the spike, and driven tight into the stone, though they are sometimes put in loose and split by driving the spike. Spikes or pins of well dried oak have been used instead of iron spikes for securing the chairs, and have been found very durable, but are not generally approved for lines worked at great speed. The introduction of a piece of felt between the chair and the block is useful in deadening concussion. As it is highly important that stone blocks should be well bedded, it is usual to cause them to form a solid foundation for themselves by repeatedly falling from a small elevation on to the spot where they are to rest, sand or very fine gravel being thrown under them between the times of falling. For this purpose a portable machine with an elastic wooden lever about twenty feet long is used, the block, to which the chair has been previously attached, being suspended from the short end, and a man stationed at the opposite end to raise and drop it. When the stone has made a firm bed, and has dropped in the right position, which is determined by levels and sights, it is detached from the lever and surrounded by ballasting, care being taken not to disturb it at all. It is evident that this careful bedding would be thrown away on an embankment, or any part where the newness of the ground would render subsidence probable. *Fig.* 13 is a ground-plan illustrating the use of stone blocks and wooden sleepers. *a*, *a*, represent blocks laid square with the road

Fig. 13.



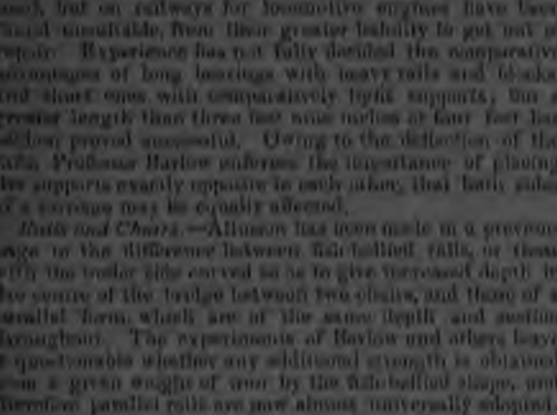
and *b*, *b* the same laid diagonally, a position now generally preferred, being convenient in repairing the road when a block sinks, because workmen can get at every side for the purpose of ramming ballast under it. Blocks of Scotch asphalte have been tried in lieu of stone, but with what success the writer is not aware. A few were laid down on the Southampton railway, and the chairs were spiked down without boring the block. Other similar substances have been suggested in order to diminish expense. It has also been proposed to use cast-iron bed-plates instead of blocks, by which several important advantages were anticipated, but no such plan appears to have been brought extensively into use. In the Dublin and Kingstown railway an attempt was made to ensure increased solidity by introducing *throughgoing* stone blocks, which were formed of granite, six feet long, two wide and one thick, and stretched across the track. These were placed fifteen feet apart, ordinary single blocks being used between them, at intervals of three feet. Owing perhaps to the difficulty of bedding such large blocks, the plan did not answer, the motion over them being harsh and unpleasant, and the vibration such as to break many of the long blocks. In some cases, particularly on sleep cross, iron threads have been used to connect two opposite chairs, and counteract any tendency to separate which might arise in such situations from the isolation of the blocks.

The use of cross-sleepers, which are represented by *i i*, *Fig.* 15, needs little remark. They are mostly from seven to nine feet long, and consist sometimes of whole trunks of small size, and in other cases of half trunks laid with the flat or sawn side downwards. These and other timbers connected with a railway are now almost always Kyanized, and the durability imparted to them by that process is greatly in favour of their use as a permanent foundation. Several lines of railway have recently been laid entirely upon these sleepers.

The distance between the points of support varies from three to five feet. Bearings of greater length have been used, but on railways for locomotive engines have been found unsuitable, from their greater liability to get out of repair. Experience has not fully decided the comparative advantages of long bearings with heavy rails and blocks, and short ones with comparatively light supports, but a greater length than three feet nine inches or four feet has seldom proved successful. Owing to the deflection of the rails, Professor Barlow enforces the importance of placing the supports exactly opposite to each other, that both sides of a carriage may be equally affected.

Rails and Chairs.—Allusion has been made in a previous page to the difference between fish-bellied rails, or those with the under side curved so as to give increased depth in the centre of the bridge between two chairs, and those of a parallel form, which are of the same depth and section throughout. The experiments of Barlow and others leave it questionable whether any additional strength is obtained from a given weight of iron by the fish-bellied shape, and therefore parallel rails are now almost universally adopted. They possess this, among other advantages, that the length of bearing on the different sides of a curved track may be so varied as to keep the chairs opposite to one another, which cannot be done with fish-bellied rails. *Fig.* 14 represents some of the principal varieties of form and contrivances for fixing the rails, which have been introduced on English railways: *a* is a section of the fish-bellied rail originally

Fig. 14.



used on the Liverpool and Manchester railway, the shaded part being that which enters the chair, and the outline indicating the increased depth in the centre.—*b* is the same rail, as fixed in the chair, the black part representing the end of an iron wedge or key, which is driven in to secure it.—*c* and *d* are a section and side view of a plan invented by Mr. Losh, and used on the Newcastle and Carlisle railway. The rails are made with a curved projection on the under side, to fit into a suitable concavity in the chair, as indicated by the dotted lines in *d*. Two iron keys are used, driven in opposite directions. Any contraction of the rail tends to draw it laterally out of the chair; but in doing so, the curved base rises in its seat and tightens the keys, which press downwards as well as sideways.—*e* and *f* are similar views of a method contrived by Robert Stephenson, and used on part of the London and Birmingham railway. In this the base of the rail is flat, but bears upon a segmental piece of iron laid loose in a concavity in the chair, so that an irregularity which may cause the chair to tilt in the direction of the rail, may not affect its position. The rails are secured by cylindrical pins, the points of which enter depressions in the side of the rail. Each pin has a slit through it, which, when in its proper position, tallies with holes through the cheeks of the chair. Iron keys driven into these holes prevent the pin from moving, and, acting as wedges against the end of the slit, force the pin tight against the rail. The chair represented is a joint chair, and *g* shows the form of the joint, which is called a half-lap. The narrow part of the rail is not divided, but turned aside at the joint, as shown by the dotted lines. Intermediate chairs are similar, but have a pin on one side only. This mode of fixing allows the rail to slide a little in the chair, on account of expansion and contraction; and the keys are not so liable to work loose as when in contact with the rail. These are all for fish-bellied, and the following for parallel rails.—*h* is a rail and chair invented by Mr. Dagliah, and rewarded by the London and Birmingham Railway Company, as presenting the best sectional form of rail. The chair is proposed to be fixed to the block or sleeper by bolts passed through from the under side, and keyed above the chair. The rail is fastened by two semi-circular iron keys driven in opposite directions. This arrangement, though ingenious, has the disadvantage that the rail could not be taken up without removing the chair.—*i* is a contrivance in which an iron ball, dropped into a socket in the chair, is forced against the rail by a key driven through a hole in one cheek of the chair. It is simple, and affords sufficient lateral movement for the effect of temperature on the rail. This form of rail is known as the T rail.—*k* and *o* are a section and ground-plan of a chair in which the rail is held by a wooden key. The keys are well seasoned, and when in use become by expansion almost immoveable; because, as shown in *o*, they are most compressed in the centre. So great indeed is the expansive force of the wood, that it occasionally breaks the chairs. This mode of construction is extensively used on the Grand Junction, Birmingham, Southampton, and other railways.—*m* and *n* show another application of a wooden fastening, adopted by Mr. Storey on the Great North of England railway. A block of wood is so placed in the chair as to be prevented from moving endways, and is held to the rail by an iron wedge driven through the cheek of the chair.—*l* is a rail contrived with the idea of fitting the wheel more accurately than those of the ordinary shape, but it is not much used. The rails here represented vary much in strength: *a* and *b* were made about thirty-five pounds to the yard, but have been found too light, and replaced by parallel rails of sixty pounds; *e* and *f* are fifty-pound rails, for three feet bearings. Rails similar to *k* are made from sixty to seventy-five pounds per yard or more, for bearings of three to five feet, and they are now seldom used of less weight than seventy pounds to the yard. The most common joints are square, as *n* and *o*, but half-lapped and scarfed or diagonal joints are also used. The concussion produced by a very slight irregularity at these points is so injurious, that probably increased care and expense in making them perfect would be well bestowed. Chairs are almost invariably made of cast-iron, as their complex form renders it difficult to manufacture them otherwise with sufficient economy; but as they are liable to breakage from their brittleness, it has been proposed to make them of malleable iron, and machinery for the purpose has been patented, but apparently not yet brought into operation.

Railways on Continuous Bearings.—The introduction of this kind of railway is perhaps mainly to be attributed to the extensive use of timber in such works in America. It has not only been used in lieu of stone, but also in a great measure in the place of iron. In many of the American and some of the Continental railroads, beams of timber laid continuously, and firmly connected together by cross pieces, are made to supply the strength usually given to iron rails; the application of iron being limited to a flat bar or plate two inches and a half wide, and from half an inch to an inch thick, nailed to the beams on their inner edges for the wheels to roll upon. Though differing in details, this construction of railway is very like the oldest form used in this country, the wooden tramway. Frequently these beams or wooden rails are supported upon cross-sleepers; but whether they are so or not, their breadth of surface causes them to receive considerable support from the ballast or road materials, along their whole length. Mr. I. K. Brunel, engineer of the Great Western railway, was one of the first British engineers who proposed a similar construction, which he did with the hope of obtaining a smoother and more elastic road, which should at once be more agreeable to ride upon, cheaper to maintain, and safer for travelling at high velocities than a railway constructed in the ordinary manner.

Although some of the supposed advantages are at present questionable, the superior smoothness of motion on such a road, when in good order, is pretty generally admitted, and an opinion seems to be gaining ground that, though longitudinal timber bearings do not produce so firm and unyielding a railway as stone blocks, and may therefore require rather more power in working, this disadvantage is more than counterbalanced by the diminished wear and tear, of which the comparative absence of noise is a tolerably accurate criterion. The Great Western railway can hardly be compared with any other, on account of its increased width, but the London and Croydon, which is entirely, and the Manchester and Bolton, Hull and Selby, and several other lines, which are partially laid in this manner, and which in other respects resemble those of the more common construction, may be fairly brought into comparison with them. The Greenwich railway is a remarkable instance of the superior comfort of timber bearings to those of stone, the rigidity of the latter being aggravated by the circumstance of being on a viaduct. On this line, as has been the case on that from Dublin to Kingstown, it has been deemed advisable to remove the blocks, and substitute a more elastic structure of wood. The longitudinal timbers on the Croydon railway vary from nine to fourteen inches wide, and four and a half to seven inches deep; and cross sleepers are bolted under them at intervals of three feet. The rails are of the form shown at *p*, *Fig.* 15, and are screwed down at intervals of eighteen inches on each side, a layer of felt being interposed between them and the timbers. These rails weigh about forty-seven pounds to the yard.—*q*, *Fig.* 15, is the rail of the Great Western railway, which is fixed

Fig. 15.

in a similar manner, but the screws on the inner side of the rail are round-headed and countersunk, while the others are ordinary square-headed bolts. The longitudinal timbers are of larger dimensions, and the cross-pieces or transoms are placed fifteen feet apart, and framed with them, their office being more to keep the track in gauge than to bear any considerable part of the weight.—*r* and *s* are forms of rail sometimes used on continuous bearings, *r* being fastened by clamps or pins driven in obliquely. Rails similar to *p* have been fixed in the same manner, but the use of screws, though expensive, is decidedly preferable.

Continuous bearings of stone have been tried, but found too harsh and rigid; and some ingenious combinations of wood or iron with natural or artificial stone or burnt clay, have been proposed, but not hitherto brought much into use.

Gauge, Width between Tracks, &c.—The gauge or width between the two rails forming a track is one of the points in railway practice which has excited much discussion. On the old railways it was of little consequence, provided a good horsepath could be ensured without interfering with the rails. Four feet was not an uncommon width, but many lines were less. Some of the colliery railways in Northumberland are four feet eight inches and a half, and from these the Stockton and Darlington, Liverpool and Manchester, and other lines, took their gauge. The advantage of uniformity has led most companies to follow this example, and for a time it was rendered imperative by parliament, but at present no standard is fixed by the legislature. The ordinary width being considered inconveniently limited, Brunel fixed upon seven feet as the gauge of the Great Western and its tributary lines. Much opposition has been made to this bold step, mainly on account of the inconvenience of not being able to connect with other lines, which is in some degree obviated by laying an inner rail for the use of narrow carriages on any portion of railway passed over by two companies whose lines are laid of different widths. The superiority of this enlarged gauge is apparent in the increased power and speed of the engines, and the stability and convenience of the carriages; but many who admit the inconvenience of the narrow gauge consider seven feet to be beyond the most advantageous width. Six feet two inches has been recommended by the Irish Railway Commissioners. Six feet is the width of some of the continental lines; the Dundee and Arbroath, and Arbroath and Forfar railways are five feet six inches; and the Eastern Counties, and London and Blackwall, about five feet. The ordinary standard in America is four feet eight inches and a half, having been copied from the Liverpool line. Several recent lines in this country have been made four feet nine inches, to allow rather more play to the flanges than the common width. One of the great recommendations of a wide gauge is the scope that it allows for improvements in machinery, a circumstance evidently of much importance when it is considered that the experience of ten years only has led to the enlargement of locomotive engines to so great a degree that their weight and cost are now nearly treble what they were when the Liverpool and Manchester railway was opened. The principal argument on the other side is that by increasing the width and bulk of carriages atmospheric resistance would become more formidable; but Dr. Lardner's experiments lead to the conclusion that this resistance is not affected by the mere *front* of a train so much as to render this objection very important.

The width between the two tracks is a matter of much less consequence, as it has little effect except in limiting the width of load that may be carried. On the Liverpool and Manchester line it is four feet eight inches and a half, which is convenient as allowing waggons to run on it during the construction of the road. The London and Birmingham railway and many others have a space of six feet, which allows loads of ten feet wide to be carried with safety. The same intermediate space on the Great Western railway, in consequence of the increased gauge, allows a maximum load of twelve feet. The space necessary outside the tracks is dependent on the width of load provided for, and seldom exceeds four feet, except on embankments, where a little more is sometimes allowed, so that in case of carriages getting off the track, there may be width for them to run on the ballasting until the inner wheels come in contact with the outer rail, which will in most cases prevent the train from overturning.

In laying the rails, allowance should be made for the effect of temperature, which will cause a difference of length in a fifteen-feet rail, exposed to a range of 70° Fahrenheit, of about $\frac{1}{11}$th of an inch. From want of attention to the temperature when the rails are laid, too much allowance is frequently made, which, especially with square joints, causes an unnecessary shock to the carriages. The insertion of a piece of wood between the ends of two rails is an ingenious mode of avoiding concussion from this cause, the wood expanding as the iron contracts.

In the description of *fig.* 8, it is stated that the wheel-tires are made slightly conical, in order that the flanges may come in contact with the rails as little as possible. In ordinary wheels three inches and a half wide, the inclination of the tire is about 1 in 7, the diameter at the outside being an inch less than close to the flange. The wheels are so fixed that when running straight the flanges are about an inch from the rails. When the rails are fixed vertically, the line of contact between them and the wheels is, in consequence of their conical shape, so narrow as to cause considerable wear. Most engineers therefore give a slight inclination inwards to the rails, that they may present a greater surface to the wheels, although the friction is increased by the rubbing of the conical tire. This inclination is stated by Lecount to be $\frac{3}{8}$ of an inch in eleven inches, or about 1 in 29, on the Birmingham railway; on the Great Western it is 1 in 20.

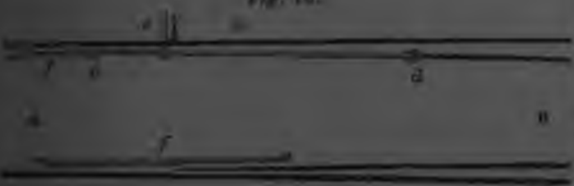
In running on a straight road, the conical tires keep the carriage in the true line of direction, because any deviation from it causes the wheels on one side to roll on an increased and those on the other on a reduced periphery, an irregularity which immediately checks itself. But on a curved track the centrifugal force overcomes that of gravity so far as to cause the flange on the outer side of the curve to approach the rail, and consequently the opposite wheels to roll on unequal peripheries, thereby avoiding part of the friction consequent on the wheels (which are fixed to the axle) being compelled to revolve with equal velocity, though the outer one has to pass over a greater length of rail than the other. To prevent unnecessary friction between the flange and the rail, it is usual to lay the outer rail on curves rather higher than the inner one, that the opposing forces may be so balanced as to cause average loads moving at the medium speed employed to pass round the curve without the flanges on either side coming in contact with the rails, and with the wheels rolling on diameters unequal in a degree corresponding with the radius of the curve. A pair of ordinary coach wheels, three feet diameter, might run in a curve of only 360 feet radius without the flanges touching; and as no curves of such small radius are admitted on a main line of railway, it is evident that, in theory, nothing more than an accurate adjustment of the outer rail with reference to the speed of transit is necessary to enable trains to pass along any ordinary railway without the flanges being called into action, unless by accidental circumstances. The following is selected from a much more extensive table by the Chevalier de Pambour, to show the proper elevation of the outer rail on a line of four feet eight inches and a half gauge, under given circumstances. The calculations are suited to the use of three-feet wheels, coned as above described:—

Radius of Curve.	Speed 20 Miles per Hour.	Speed 30 Miles per Hour.
1000 feet.	1·44 inch.	3·30 inches.
2000 "	·71 "	1·65 "
3000 "	·47 "	1·10 "
4000 "	·36 "	·83 "
5000 "	·28 "	·66 "

Stations, Passing-places, &c.—The convenient arrangement of the stations and depôts on a railway where an extensive and varied traffic is carried on, is a matter requiring much attention. As a general rule it is best to have them as nearly as possible on a level with the surrounding land, both to save expense in construction, and to avoid inconvenience in the transfer of goods from the railway to common road vehicles, and *vice versâ*. Wherever a higher or lower level is unavoidable, approaches of moderate inclination should be made for carriages. The station of the Brandling Junction railway at Gateshead is of novel and ingenious design. The line is on a viaduct, the arches of which are extended so as to support a level of considerable extent. A branch track at right angles with the main line is laid along the crown of each arch, by which waggons are conducted to platforms that form part of the railway level, but may be lowered, with waggons upon them, to that of the warehouses, which are underneath the arches, and communicate with the natural surface. Stations vary in character, from mere booking-offices, where passengers and parcels wait to be taken up by passing trains, to great establishments covering several acres of ground, with separate offices for passengers, parcels, and heavy goods; facilities for transferring carriages, horses, and cattle to or from the railway; extensive sheds for trains to stand under, repairing-shops for engines and carriages, and many other necessary erections. The stations of the London and Birmingham railway at Euston Square, Camden Town, and Birmingham, extend collectively over a space of about fifty acres; besides which the company have establishments of great magnitude at Wolverton, Rugby, and Hampton, and several of smaller dimensions. The original estimate for the stations was [illegible]*l.*; but in consequence of the necessity of arrangements for a greater traffic than was anticipated, about ten times that sum has been expended upon them.

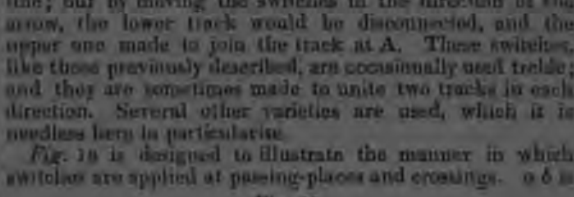
Contrivances for conducting engines and carriages from one track to another are required in a variety of situations. They generally consist of switches and turntables, so modified as to suit particular cases. *Switches* are moveable rails placed at the point where two tracks fall into one, and capable of adjustment so as to guide vehicles from the single track into either of the two, or from either of the two into the single track. In the old railways this was effected by short tongues of iron, moved by hand; but it is necessary where locomotives are used to have the transition from one track into the other as gradual and free from concussion as possible, and therefore the moveable bars are made of considerable length, seldom less than eight or ten feet, and, on the Great Western railway, fifteen feet. *Fig.* 16 represents

Fig. 16.



a switch formed on the model of the old contrivance of moveable tongues. The black lines are the fixed rails, which at A form but one, and at B two tracks. The double line from *c* to *d* indicates the switch, which is pivoted at *d*, and tapered to a point at the other end. From its under edge proceeds the bar *e*, which passes under the rail to a lever or eccentric placed in a convenient situation for being moved by an attendant. In the position represented by the engraving, the switch would conduct a train along the upper track from A to B, because free passage is allowed for the flange between the switch and the upper rail, while the inside of the flange pressing against the switch *c d* prevents the flange on the opposite side of the track from quitting the straight course. If however, by turning the lever or eccentric connected with *e*, the switch is moved in the direction indicated by the arrow, the case will be reversed; the switch being brought into contact with the rail at *c*, the flange will be compelled to move along its inner side, and consequently that on the opposite side of the track will pass along the opening by the side of the lower rail. *f f* are fixed bars called guard-rails, which prevent the switch moving too far, and protect the narrow ends of the switch and rail from injury. Switches on this principle sometimes connect three tracks with one by *two* moveable pieces, of which an example is in use at the Great Western railway station at Paddington. A great recommendation of this kind of switch is, that unless the moveable rails are *fixed* in a wrong direction, a train can never get off the track, as the momentum enables the flange to open the switch and pass through. In some situations a spring or weight is applied with great advantage, to hold the switch in the position most commonly required, and return it to that position immediately after being acted upon. The double rail, represented in *fig.* 17, is a contrivance much used as a switch, and affords a very smooth transition from one track to another. In this the two tracks terminate in two double rails, *c d* and *c' d'*, pivoted at *d d'*, and shifted as occasion requires in a similar manner to the former, the rails being connected by cross-pieces, so that the whole are

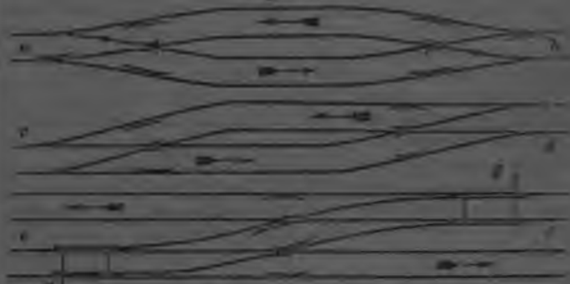
Fig. 17.



moved simultaneously. In the present position of the apparatus the lower track is that connected with the single line; but by moving the switches in the direction of the arrow, the lower track would be disconnected, and the upper one made to join the track at A. These switches, like those previously described, are occasionally used treble; and they are sometimes made to unite two tracks in each direction. Several other varieties are used, which it is needless here to particularise.

Fig. 18 is designed to illustrate the manner in which switches are applied at passing-places and crossings. *a b* is

Fig. 18.

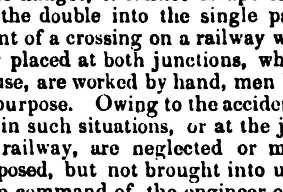


a passing-place for a single line of railway where the traffic is about equal in each direction. It should be observed that the angles in this figure are, to save room, made more abrupt than they should be on a public railway, where angles of more than 2° or 2½° are considered objectionable. In this arrangement every train from *a* to *b* takes the lower track, and those from *b* to *a* the upper one. Switches of the kind first described are used at the points *a* and *b*, and, as they have always to be passed through in the same order, they are made self-acting, that at *a* being held by springs in the position for guiding carriages on to the lower track, and being opened by the flanges of the engine-wheels for the passage of the trains in the contrary direction, while that at *b* in like manner conducts trains passing towards *a* into the upper track. This kind of passing-place has been successfully used on the Newcastle and Carlisle and other railways. *c d* represents another arrangement for the same purpose, which may have the same kind of switch, but is generally used without any, the impetus of the train always keeping it to the straight track, while, if suitable openings be made for the flanges, it cannot escape from the rails in running from the double into the single part. *e f* shows the arrangement of a crossing on a railway with two tracks, switches being placed at both junctions, which, being only for occasional use, are worked by hand, men being stationed at *g g* for the purpose. Owing to the accidents which occur when switches in such situations, or at the junction of two main lines of railway, are neglected or misplaced, plans have been proposed, but not brought into use, for placing them under the command of the engineer of an approaching train, who cannot be absent from his post. It is usual to affix a signal apparatus to them, which, by displaying a coloured disk of wood or stretched canvass to the engine-driver, informs him of the position of the switches as he approaches them, and affords an opportunity of checking his speed if they are wrong.

At the points where two rails cross, grooves are formed to allow the flanges to pass; and, to check any tendency in the wheels to escape from the rails, guard-rails, as indicated in *Fig*. 18, are fixed within the track, to guide the inside of the flanges.

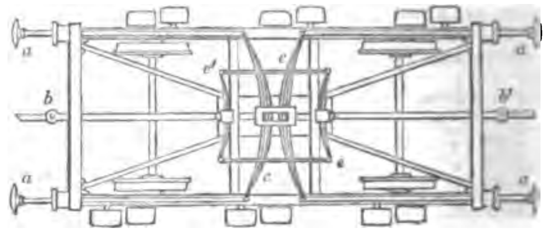
Turn-tables are useful in transferring single carriages from one track to another, which they do in much less space than any arrangement of crossings and switches. They consist of circular platforms of iron and wood, fixed on a level with the tracks, and mounted on friction-wheels, so as to turn on their centres with great facility. *Fig*. 19 represents two turn-tables so laid as to communicate with one another. Four rails are laid across each, and made to tally precisely with those of the track. If it be desired to transfer a carriage from the track *a* to that marked *b*, it is rolled on the turn-table at *d*, and then, the catches which held the turn-table steady being released, the platform, with the carriage upon it, is turned a quarter round. The carriage is then rolled on the turn-table *e*, and being again turned a quarter of a circle, is in a right position for running on the track *b*. Carriages may in like manner be transferred to a cross-track, as at *c*. Locomotive-engine houses are frequently made octagonal, with eight radiating tracks, the engines being moved to or from any of them by means of a large turn-table in the centre. That at Camden Town has sixteen tracks connected in this manner.

Fig. 19.



Carriages.—Railway carriages for the conveyance of passengers are usually very capacious, the bodies being made to project over the wheels, which on ordinary lines seldom exceed three feet diameter. This arrangement is not productive of danger, since the evenness of a railway, the comparatively low build of the carriages, and the great weight of the iron wheels, axles, and framing under the body, prevent the liability of overturning. On account of the rapid speed at which they travel, and the violent shocks to which they are occasionally subject, great strength of construction is necessary; and the circumstance of several vehicles being linked together in one train renders the use of an elastic apparatus for starting and stopping them essential, both for the safety and comfort of passengers, and the protection of the vehicles themselves. Elasticity in the traction is also necessary, in order that the engine may not have to overcome the inertia of the whole train at the same instant, which would require much more power than suffices, when they are started, to keep the whole in motion. Various contrivances, more or less complete and effective, are in use for this purpose, but *fig*. 20 may serve to give a correct idea of the principles on which they all act. It represents the ground-plan of a passenger-carriage, the body being removed. The frame, which is outside the wheels, is supported on lapped springs, which, by brass bushes or bearings, rest on the ends of the axles, they being extended beyond the wheels, and accurately turned, for that purpose. *a a a a* are buffers, or discs of wood or metal, sometimes covered with cushions, fixed on the ends of long rods which pass through the frame and along the sides to the ends of the long springs *c c*, which are capable of moving towards each other when pushed by the rods, but are prevented by stops on the frame from moving in the opposite direction. The centre being allowed to slide backwards and forwards, both springs are brought into action by an impulse given at either end. All the buffers in a train being placed at the same height and width, they come into contact when the carriages run towards one another in stopping suddenly, and the jerk is by them communicated to the springs, whose elasticity allows so much motion as to prevent any injurious shock to the carriage. The traction apparatus, or that by which the carriages are drawn forward, consists of rods passing through the frame at *b b'*, and connected in a manner which it is unnecessary to describe, with the small springs *e' e*, which also act together, the centre of *e* pressing against the cross-bar of the carriage-frame as an abutment when the pull is from *b*, and that of *e'*, in the like manner, when the traction is in the direction of *b'*. The connection between the different carriages often consists of a jointed bar of iron, which is disconnected, when necessary, by the removal of a pin. Chains are sometimes used, and occasionally united by a peculiar kind of screw, which draws the carriages so close that their buffers come in contact. In some carriages the same springs serve both for traction and buffing, and spiral or helical springs are not unfrequently applied to the purpose. Axle-guides, fixed to the frame, are used to keep the axles square; but a more elastic construction of carriage, in which the axles have sufficient play to enable them to adapt themselves to a curved track, and the springs for bearing the weight, drawing, and buffing, are made of an unusually light character, is being introduced by Mr. Adams, with great promise of success. Many engineers appear to be of opinion that the construction of carriages, as well as of the railroad itself, has hitherto been too rigid, and Mr. Adams conceives that the adoption of bow-springs, and other improvements, will at once increase the comfort and safety of railway conveyance, and diminish the wear and tear, which, with the present heavy and comparatively inelastic carriages, is very great. The ordinary first-class carriages convey eighteen passengers, having a treble body, with six seats in each compartment; and the second-class, of similar make, carry twenty-four passengers. Those on the Great Western railway, which are mostly on six wheels, are much larger, some of the second class vehicles seating seventy-two persons. The wide gauge allows the use of bodies so large that some are fitted up as elegant saloons. A splendid carriage, about twenty-eight feet long and nine wide, has been recently prepared for the use of Her Majesty and suite, when travelling on this line. Open carriages, in which the passengers stand, are frequently used for short stages. Waggons for goods and cattle, trucks for the conveyance of stage-coaches and private carriages, and horse-boxes, are all mounted on springs, but their buffing-apparatus is often very simple and inelastic. The weight of the ordinary passenger-coaches, when empty, is mostly from three to five tons.

Fig. 20.



Locomotive Engines.—In the rapidly extended applicatem of locomotive steam-engines, since their successful adoption on the Liverpool and Manchester railway, improvements have followed closely upon one another, but they have been chiefly of a minor character, when compared with that of tubing the boiler, which formed the distinguishing feature of the Rocket engine. Stephenson built several engines shortly after the competition in which the Rocket had proved victorious, retaining this arrangement, but having the machinery disposed in a different manner. The cylinders were placed in a box beneath the chimney, and the piston-rods moved horizontally under the boiler, working two cranks formed on the axle of the hind wheels, which were then made the largest. The boiler and machinery were attached to a massive frame, the sides of which were outside the wheels, and rested, by means of springs and brass bearings, on the ends of the axles. Bearings outside the wheels have this decided advantage over inner ones,—which are nevertheless preferred by some engineers,—that the ends of the axles may be turned away to so small a diameter as materially to diminish the friction, without the risk of breakage which would attend the reduction of the axle within the wheels. The superior economy of large engines becoming evident from experience, it was deemed advisable to add a third pair of wheels, which were made small, like the fore-wheels, and placed under the fire-box end of the machine. The flanges on the two pair of small wheels being sufficient to guide the machine, Stephenson removed them from the central or driving pair, which thus became mere rolling or propelling wheels, and were relieved from the lateral strains arising from the flange coming in contact with the rail at curves and switches, such strains having been found injurious to the cranked axle and the machinery connected with it. Some engine-builders still retain all the flanges, from an idea of greater security. The following figures may give some idea of the locomotive engine in this improved state, in which form it is now in use upon most of the railways in this country, and several on the Continent and in America. *Fig.* 21 is an elevation, and *fig.* 22 a longitudinal section, in which many minute details are omitted, for the sake of distinctness.

Fig. 21.

Fig. 22.

a is the fire-box, usually formed of copper, and surrounded by an outer casing of iron, leaving a space of three or four inches all round, which is filled with water and forms part of the boiler. The door by which the fire is supplied with coke is made of two iron plates, with a space of a few inches between them, to prevent the radiation of heat. Coke is carried in the tender, a supplementary vehicle attached to the back of the engine. The fire-box is usually open at the bottom, to allow the free access of air, so that cinders fall through the bars upon the road, a circumstance sometimes productive of accident. As there is very little water above the flat top of the fire-box *a*, a fusible plug is inserted in it, to act as a safety-valve in the event of the water becoming too low, and leaving it dry. The tubes through the boiler *b* for the passage of flame and heated air are now always made of brass, which is found much more durable than copper. They vary in number in different engines from about ninety to a hundred and fifty or upwards, being frequently less than an inch and a half in diameter. The power of generating steam, which is the measure of efficiency in a locomotive engine, depends much upon judicious tubing, it being desirable to deprive the heated air of its caloric as completely as possible before leaving the boiler. The chief practical limit to the reduction of the tubes, and consequent increase of their number and extent of surface, is their liability to become choked with cinders and ashes carried into them by the draft. Boilers are frequently tubed to such an extent that from four to six hundred square feet of heated metal is exposed to the water, in addition to the area of the fire-box itself. An important feature in a locomotive boiler is its security from bursting, because, as the tubes are much weaker than the external casing of the boiler, they are almost certain to give way first, and the bursting of one or two tubes is rarely productive of more serious consequences than extinguishing the fire, and thereby causing a gradual stoppage of the machine.

Owing to the limited size of the boiler, the steam which collects in the upper part is mixed with spray from the water. A steam-chamber *d* is therefore added, in which it becomes free from the spray, and then enters the steam-pipe that passes through the smoke-box *c* to the cylinders or engines at *e*. A throttle-valve in this pipe is placed under the command of the engineer by a rod passing through the boiler and terminating in a handle connected with a graduated scale at the back of the engine. By this the supply of steam to the cylinders is regulated or cut off when necessary. The action of the pistons and connecting-rods needs no explanation here. Eccentrics for working the slide-valves, which admit steam alternately to each side of the piston, are fixed on the main crank-axle, and in some engines two pair are used, one for working in common, and the other when the engine runs backwards. The steam cylinders are usually twelve or thirteen inches diameter, and eighteen inches stroke; and the driving wheels of the engine from five to seven feet diameter, the small wheels being three or four feet. Driving-wheels of eight and ten feet diameter have been tried on the Great Western railway; but the most common diameter on that line is seven, and on railways of the ordinary gauge five or six feet.

The pipe shown in the section passing from the cylinders to the chimney is the blast-pipe for the exit of waste steam, its upper end being tapered to give greater effect to the jet. At the top of the chimney a wire-gauze cap is frequently fixed to arrest sparks and small cinders which are often thrown up by the strong draft, and have been the occasion of many destructive fires; but a more effectual remedy has been recently introduced, consisting of a grating at the bottom of the chimney, which stops the cinders before they are affected by the steam-jet. *f* and *g* are safety-valves held down by springs, the former only being under the control of the engine-driver. *h* is a steam-whistle, which by its shrill sound warns persons working on the line of the approach of an engine. *i* is one of two feed-pipes, communicating between the water-tank in the tender and small forcing-pumps under the boiler, which are worked by the engine, and ensure an equable supply of water in the boiler. Valves for regulating this supply, handles for reversing the motion of the machine, steam and water gauges, and numerous other conveniences are added, being placed within reach of the engine-driver, when on the platform at the back of the fire-box. In order to economize the heat by checking its radiation, the boiler is coated with wood, and sometimes flannel is placed between them. The steam-dome and similar parts are double, the space between the inner and outer casing answering the same purpose. The tender, and sometimes the engine itself, is supplied with powerful brakes, to arrest the motion of the wheels when necessary. Some of the carriages also have them, handles for working them being placed within reach of the guards.

On some lines of railway, as the London and Birmingham, engines on only four wheels, with circular fire-boxes, and the axle-bearings within the wheels, are still used; and some engines have been recently introduced on the Hull and Selby railway, in which an attempt is made to combine the advantages of inside and outside bearings, by throwing a great part of the weight on bearings within the central or driving-wheels, while steadiness of motion is insured by external bearings to the fore and hind wheels. Where increased adhesion is desirable, as for luggage engines, or such as are intended to ascend steep gradients, four, or even six wheels are coupled together by external cranks and connecting rods, such wheels being of course of equal diameter.

Many of the American locomotives are arranged in a different manner from that described, with a view to greater facility in passing along curves; the forepart of the machine being supported on a four-wheeled truck, which is capable of adjusting itself to a curved track. It is a singular fact that while British engines have been sent to America for working several lines, an American manufacturer has competed successfully with those of England in building locomotives for the Birmingham and Gloucester railway.

Harrison's patent locomotive, though not extensively introduced, deserves mention for its bold departure from the established model, the boiler and engines being mounted on separate carriages. These have been built with ten-feet driving-wheels, and also with five-feet wheels, the velocity of which is made treble that of the cranked axle by the intervention of a toothed wheel and pinion. Hitherto no very striking advantage has been realised by these arrangements.

Stationary Engines.—The heavy expenses attending the use of locomotive engines, from the rapid action of the working parts, the addition of their own weight to the load to be conveyed, and the injury they cause to the rails, lead some persons to conceive that stationary engine-power might be applied more advantageously. The working of stationary engines themselves is unquestionably the most economical, but the friction of ropes to convey their power to the carriages forms a serious drawback. Hitherto they have been little used except for steep inclined planes, which, as at Camden Town and Liverpool, are worked by an endless rope, conducted along both tracks by grooved pulleys or sheaves, to keep it off the ground, and passing at each end round a wheel fixed below the level of the road, the upper one of which is turned by the engine. A contrivance is added to keep the rope always at the requisite degree of tension. It has been proposed, in hilly countries, to use natural or artificial falls of water instead of steam-engines for such an apparatus. Another mode of employing the power of stationary engines is by means of what are called *tail-ropes*, an ingenious application of which has been recently adopted on the London and Blackwall railway, and seems well adapted for working a railway in which numerous stations are required within a short distance. Very powerful engines are erected at London and at Blackwall, each of them turning a grooved wheel, to which a rope of nearly six miles and a half (double the length of the railway) is attached. A train starting from London is arranged with the Blackwall carriages foremost, and then those for the intermediate stations in such order that the vehicle required to stop first shall be last in the train. At a given signal, the Blackwall engine commences winding up the rope, by which the train is drawn forward at a speed of twenty to thirty miles per hour. On approaching the first station, the carriage intended to stop there is detached from the train by the guard, and stopped by means of a brake, the rest of the train proceeding without interruption; and, in like manner, vehicles are left behind at all the stations. In addition to drawing the train, the Blackwall engine unwinds the rope from the barrel of that at London, which is thereby prepared for moving the train back again when reloaded. In returning each carriage is attached to the rope, and the whole are drawn simultaneously, though on different parts of the line, towards the London terminus, where they arrive at different times, but in the proper order for another journey. This description applies to one track only, but the line has two, each having a similar apparatus, and being worked alternately in both directions. The necessary signals are made by an electric telegraph, invented by Messrs. Wheatstone and Cooke. This important appendage to a railway is described in the article TELEGRAPH. However desirable rope-traction may be under the peculiar circumstances of the Blackwall line, it is attended with great expense from the wear of the ropes, which are very costly; and, notwithstanding every precaution, the noise of the numerous sheaves that support the rope is annoying. To obviate these objections is a principal object of the invention called the 'atmospheric railway,' which, within a few months past, has been successfully tried on a length of about half a mile on the West London (formerly called the Thames Junction) railway, at Wormholt Scrubbs. The apparatus consists of an iron pipe nine or ten inches diameter, extending along the middle of the track; in which a piston is caused to move with a velocity of from twenty to thirty miles an hour, by exhausting the tube in front of it, and admitting the air to press on the opposite side. A connection is formed between this piston and the carriages by a rod passing through an opening along the top of the tube, which is kept air-tight by a well-contrived valve that opens to allow the passage of the rod. The necessary vacuum is produced by air-pumps, worked by a stationary steam-engine. Though several similar propositions have been previously made, that of Mr. Pinkus being, except in the kind of continuous valve used, almost identical with the present, the credit of proving the practicability of the principle on a large scale is due to Messrs. Clegg and Samuda, who anticipate advantages from it which it would be premature here to enumerate. One, which applies alike to all plans of working with stationary engines, is the improbability of collision, as but one train can be moved upon the same engine length of railway at once; as a set-off to which there is the inconvenience that a casualty to one part of the apparatus deranges the working of the whole line.

When railways were first proposed for the purposes of general traffic, it appears to have been considered that competition in the supply of locomotive power and travelling accommodation might be advantageously encouraged: and consequently clauses were introduced in railway Acts to enable any person to run engines and carriages on the payment of certain specified tolls, and subject to such regulations as might be made by the company to whom the road belongs. Such powers have been very rarely put in practice, and it is obvious that they may be virtually nullified by the refusal, on the part of the company, to supply some necessary facilities. But if such were not the case, it is the deliberate opinion of the late Parliamentary Committee, founded on careful inquiry, 'that it is indispensable, both for the safety and convenience of passengers and the public, to prohibit, as far as locomotive power is concerned, the rivalry of competing parties on the same line of railway;' also 'that railway companies using locomotive power possess a practical monopoly for the conveyance of passengers on the several lines of railway; and that under existing circumstances this monopoly is inseparable, from the nature of their establishments, and from the conduct of their business, with due regard to the safety and convenience of the public.' As far as regards the supply of locomotive power and the general control of the trains, a similar arrangement is essential in conducting the traffic in merchandise; but much difference of opinion exists as to the best system of managing this department of business. Some companies merely supply locomotive power and carriages, leaving the details of the business in the hands of the carriers; some have a complete monopoly of merchandise traffic, the companies acting as carriers themselves; and others combine the two systems, the companies being carriers, but conveying goods for private carriers also. On these and various other points much interesting and valuable information will be found in the 'Reports of the Select Committee on Railway Communication,' in the sessions of 1839 and 1840, with the voluminous evidence and appendices. These enter upon many subjects that have been necessarily omitted here for want of space, one of which is the passenger-tax, which is levied under the Act 2 & 3 Will. IV., c. 120, and amounts to one-eighth of a penny per mile for every passenger carried. The Committee, in order to encourage railway companies to extend the benefit of their undertakings by low fares, recommend a graduated tax, to press very lightly on the lowest fares, and form an increasing per centage as they rise to the highest rate allowed. At the recommendation of this Committee an Act has been passed for the regulation of railways (3 & 4 Vict., c. 97), which requires that a month's notice shall be given to the Board of Trade before the opening of any railway or portion of railway, for the conveyance of passengers or goods; and empowers the Board to call for returns from the railway companies of the amount of the various descriptions of traffic, of all accidents attended with personal injury, and of all tolls, rates, and charges levied on passengers, cattle, and goods. The Board of Trade are also allowed to appoint inspectors, who may enter upon and examine the works, stations, engines, carriages, &c. of any railway company; such inspectors not to be persons who have held any office of trust or profit under a railway company within one year of their appointment. The Act further provides for the prosecution at the public expense of companies who may not have complied with its provisions or those of any other Act under which they are regulated; and for the punishment, by fine or imprisonment, of the servants of railway companies, or any other persons wilfully, maliciously, or negligently endangering the safety of the works or carriages, or of the passengers conveyed, and of persons trespassing upon the line or stations. The power of arbitration in certain cases of dispute, and of confirming or disallowing any bye-laws of the companies, is also vested by this Act in the Board of Trade, whose new functions bid fair to be the means of collecting much important and interesting information on various points of railway economy. The conveyance of mails on railways is regulated by the Act 1 & 2 Vict., c. 98.

(Wood's *Practical Treatise on Railroads, &c.*, 3rd edition, 1838; and Lecount's *Treatise on Railways*, reprinted from the new edition of the 'Encyclopædia Britannica,' are among the most generally useful works on the subject of this article.)

BRITISH RAILWAYS.

The railways laid down before the present century were mostly of very limited extent; and being for the use of private establishments, were usually formed without the authority of an act of parliament. The earliest railway Act that has come under the notice of the writer is a private act of the 31st Geo. II., 1758, respecting a waggon-way for the conveyance of coal to Leeds, an undertaking interesting from its having been worked for some years by Blenkinsop's patent locomotive engines, with toothed driving-wheels working into a rack-rail. Several of the early canal Acts contained clauses empowering the companies to lay railway branches or to make railways instead of canals in certain situations where difficult works or extensive lockage would otherwise occur. The first railway established in this country as a distinct undertaking, and intended for public use, was the Surrey iron railway, the company for which was incorporated in 1801.* In the following twenty years only twenty new railway companies were incorporated; but the Stockton and Darlington railway, the Act for which passed, after much opposition, in 1821, gave an impulse to this kind of enterprise. It was opened in 1825, and accomplished far more than any previous line had done in adapting railway communication to the purposes of ordinary commercial intercourse. The annexed table shows the number of undertakings in the ten years immediately succeeding this event to have been fifty-four, of which, though many were of minor importance, several were passenger railways, and adopted locomotive engines as the moving power. The years 1836 and 1837 added forty-four more to the list, most of which were extensive undertakings. Alterations in the mode of obtaining railway Acts, combined with other circumstances, have imposed such a check on new projects, that only five have been sanctioned since that time, although the number of Acts for alterations and extensions, and for raising additional capital, has been considerable. The following table shows the number of railway Acts passed from 1801 to 1840, distinguishing those for new undertakings from such as give amended or enlarged powers to companies previously incorporated. Acts empowering canal companies to lay railways are not included.

Year.	New Lines.	Amendments.	Total.	Year.	New Lines.	Amendments.	Total.
1801	1	0	1	1822	0	1	1
1802	2	0	2	1823	0	1	1
1803	1	0	1	1824	2	1	3
1804	1	0	1	1825	8	1	9
1805	0	1	1	1826	10	1	11
1806	0	2	2	1827	1	5	6
1807	0	0	0	1828	5	5	10
1808	1	0	1	1829	5	4	9
1809	3	0	3	1830	5	3	8
1810	1	1	2	1831	5	4	9
1811	3	1	4	1832	5	4	9
1812	2	1	3	1833	5	6	11

1816	1	0	1	1837	15	27	42
1817	1	0	1	1838	2	17	19
1818	1	0	1	1839	3	24	27
1819	1	0	1	1840	0	24	24
1820	0	1	1				
1821	2	1	3		135	164	299

The total length of the lines sanctioned by acts of parliament is near 3000 miles, of which a few have been either partially or entirely abandoned. Omitting lines of little public interest, those intended for the conveyance of passengers and merchandise by steam-power amount to upwards of 2000 miles, of which more than 1100 miles are now in operation. The total amount of capital is 68,825,293*l.*, of which near one-third is allowed to be raised by loan. Deducting the capital of lines not proceeded with, or of only private interest, and making ample allowance for sums authorised, but not required, it appears that about 50,000,000*l.* has been invested in this country alone, in the introduction of a system which, but a few years since, had to struggle into existence through opposition arising perhaps as much from incredulity and ignorance as from self-interest.

The prospects of success as commercial undertakings are very different, but railways have invariably been found greatly to increase the amount of travelling, and the receipts of those lines which have been longest in operation are truly surprising. On the 260 miles of railroad connecting London, Birmingham, Liverpool, Manchester, and Preston, with the branch to Aylesbury, the gross receipts for the year ending June 30th, 1840, were 1,467,262*l.* 19*s.* 6*d.*, or upwards of 5644*l.* per mile; and this astonishing amount of income seems likely to be materially exceeded in future.

The following tables contain every railway for which an act of parliament has been obtained since 1801, with the exception of eleven; the Anglesey, 1812; Berwick and Kelso, 1811; Dulais, 1826; Exeter and Crediton, 1832; Limerick and Waterford, 1826; Manchester and Oldham, 1826; Peak Forest, 1816; Rutherglen, 1831; Sheffield and Manchester, 1831; Usk, 1814; and West Lothian, 1825; none of which have been executed, or are likely to be so. There are some private undertakings, as the Stanhope and Tyne, Stockton and Hartlepool, &c., which are of more general interest than many contained in the table; but as it would be difficult to draw a line of separation, it has been considered better to exclude all for which parliamentary powers have not been procured; and, with the exceptions just named, to embrace all which have been so sanctioned. The number prefixed to each line is merely for convenience of reference. The date of opening, when not otherwise stated, is that of opening throughout, and where the precise period could not be ascertained, a dash is inserted to indicate that the line is completed. The length given is generally exclusive of branches. In the column of 'Original capital' the first line shows the amount of that in joint-stock, which usually indicates the estimated expense of the works; the second, the further sum allowed by loan or new shares; and the third, the total sum authorised by the act of incorporation. In the second column of capital the same arrangement is not maintained, because it is frequently optional with companies to raise additional sums by loan or new shares. The sum in this column sometimes exceeds the outlay of the company, owing in some cases to the issue of shares at a sum considerably under their nominal value; and in others, to the company having taken powers for raising money to a greater extent than has proved necessary. Where the second column of capital is blank, it intimates that no powers for raising additional money have been obtained.

* Tredgold, in his 'Practical Treatise on Railroads,' &c., 1825, mentions a railway Act of the year 1738 [illegible] Such a railway, or part of it, was formed, and the experimental locomotive of Trevithick was tried upon it in 1804; but the Act, if such [illegible] 1771. The length of the line, [illegible]

RAILWAYS OF ENGLAND AND WALES.

NAME.	COURSE.	Date of Act.	Date of Opening.	Length in Miles.	Branches, &c.	Power used.	Original Capital.	Present Capital.	REMARKS.
1. Avon and Gloucestershire.	No. 13 at Mangotsfield, to the Avon, near Bitton, Gloucestershire.	1828	1832	4½	To collieries. Joins No. 13.	Horses	£21,000 10,000 31,000	£46,000	To connect quarries and collieries with the Avon. Gauge, 4 ft. 8½ in.
2. Aylesbury . .	No. 53 at Cheddington, 35 m. from London, to Aylesbury, Bucks.	1836	1839	7	Joins No. 53.	Locom. Engines.	50,000 16,000 66,000	..	For passengers and general traffic. Leased to No. 53 company. Gauge, 4 ft. 8½ in.
3. Birmingham & Derby Junction.	Nos. 4, 33, and 53, at Birmingham, to Nos. 65 and 71 at Derby.	1836	Part 1839	Total 48½	To No. 53, at Hampton. *See* 4, 33, 53, 65, & 71	Locom. Engines. 2 incl. pl.	630,000 200,000 830,000	1,056,666	For passengers and general traffic. Gauge, 4 ft. 8½ in.
4. Birmingham & Gloucester.	Nos. 3 and 53 at Birmingham, to No. 17 at Cheltenham, and by it to Gloucester.	1836	Part 1840	45 Brs. 8	To Tewkesbury, &c. Joins 3, 17, and 53.	Locom. Engines.	950,000 316,666 1,266,666	..	For passengers and general traffic. The company to use 7 m. of No. 17. Gauge, 4f 8½ in.
5. Bishop's Auckland and Weardale.	Black Boy Branch of No. 87, to Witton Park Colliery, all in Durham.	1837	In progress.	..	To Crook. Joins No. 87.	Locom. Engines allowed.	72,000 24,000 96,000	..	For the conveyance of coal, passengers, &c.
6. Blaydon, Gateshead, and Hebburn.	No. 68 at Blaydon, by Gateshead, to Hebburn Quay, on the Tyne.	1834	..	..	Several allowed. *See* Nos. 34 and 68.	..	60,000 20,000 80,000	..	Part of the line was bought by No. 68 company.
7. Bodmin & Wadebridge.	From near Bodmin to Wadebridge, parish of St. Breoke, Cornwall.	1832	1834	12	To Bodmin, &c.	Locom. Engines.	22,500 8,000 30,500	35,500	For minerals, passengers, &c. A single track, 4 ft. 8½ in. gauge. Speed abt. 8 m p. h.
8. Bolton & Leigh	Bolton to the Leeds & Liverpool Canal at Leigh, Lancashire.	1825	June, 1831	7½	Joins Nos. 44 & 61.	Locom. & fixed Engines.	44,000 in shares.	170,500	For minerals, merchandise, passengers, &c. A single track; gauge, 4 ft. 8½ in.
9. Bolton and Preston.	No. 61 at Bolton, by Chorley, to No. 72 at Euxton, Lancashire.	1837	In progress.	14½	Joins Nos. 61 & 72.	Locom. Engines intended	380,000 126,000 506,000	..	For passengers and general traffic. Originally intended to run direct to Preston.
10. Brandling Junction.	No. 68 at Redheugh, through Gateshead, to South Shields and to Monkwearmouth.	1835	Sept. 1839	Total 15½	Joins No. 68.	Locom. eng. some incl. pl.	110,000 36,000 146,000	400,000	For passengers, coal, and general traffic. Gauge, 4 ft. 8½ in.

75. Portland . .	The Priory Lands to near Portland Castle, Isle of Portland.	1825	—	2	..	Fixed Engines.	5,000 2,000 7,000	..	A plate-railway, for the conveyance of Portland stone for shipment
76. Preston & Longridge.	From near St. Paul's Square, Preston, to Longridge Fell, Lancashire.	1836	May, 1840	7	..	Horses.	30,000 10,000 40,000	..	For the conveyance of Longridge stone, heavy goods, &c. A single track.

(*d*) In addition to the parliamentary capital of 5,500,000*l*., the directors have been authorised to raise 250,000*l*. on loan notes.

(*e*) The Company purpose constructing the railway from Manchester to Crewe and Macclesfield only, and have abandoned their works on the original main line to Chebsey. As now amended, the length will be 28½ miles from Manchester to Crewe, and the Macclesfield branch 11 miles.

NAME.	COURSE.	Date of Act.	Date of Opening.	Length in Miles.	Branches, &c.	Power used.	Original Capital.	Present Capital.	REMARKS.
77. Preston and Wyre.	No. 46, at Preston, to Fleetwood-on-Wyre, Lancashire.	1835	July, 1840	19¼	Joins No. 46.	Locom. Engines	£130,000 40,000 170,000	£[illegible]00,000	For passengers and general traffic. Chiefly a single track. Gauge 4 f. 8½ in.
78. Redruth and Chasewater (or Deveron).	Redruth to Point Quay, Restrougett Creek, Cornwall.	1824	—	14	To mines, &c. Joins No. 40.	Horses	22,500 10,000 32,500	..	For minerals, merchandize, &c.
79. Rumney . .	Rumney Ironworks to No. 85 at Bassaleg, Monmouthshire	1825	—	21¼	Joins No. 85.	Horses	47,100 20,000 67,100	..	A plate-railway for minerals, &c.; runs parallel with the river Rumney.
80. St. Helen's and Runcorn Gap.	Cowley Hill Colliery, St. Helen's, to Runcorn Gap, on the Mersey.	1830	—	Total 12	To collieries, &c. Joins No. 50.	Locom. and fixed Engines.	120,000 30,000 150,000	220,000	Chiefly for coal, but a few passengers conveyed. Gauge, 4 ft. 8½ in.
81. Saundersfoot .	Thomas Chapel Mountain to Saundersfoot Harbour, Pembrokeshire.	1829	—	..	Short Branches	..	17,500 8,000 25,500	..	For coal, &c. The Act provides for the improvement of the harbour.
82. Severn & Wye	From the Severn, near Lydney, to the Wye, near Ruardean, Gloucestershire.	1809	—	Total 26	Several, to collieries &c.—Joins No. 66.	Horses	35,000 20,000 55,000	115,000	For the conveyance of minerals, timber, &c., from the Forest of Dean.
83. Sheffield, Ashton-under-Lyne, and Manchester	Spital Fields Sheffield, by Penistone, &c., to No. 60, at Manchester.	1837	In progress.	40	Joins No. 60	Locom. Engines intended	700,000 233,000 933,000	..	For passengers and general traffic. A tunnel 3 m. long, 16 ft. wide, for one track.
84. Sheffield and Rotherham .	From Brightside, Sheffield, to near West Gate, Rotherham.	1836	Oct. 1838	5¼ Br. 1¼	To Greasborough. Joins No. 71.	Locom. Engines	100,000 30,000 130,000	200,000	For passengers, coal, and general traffic. Gauge, 4 ft. 8½ in.
85. Sirhowey . .	From near Newport, Monmouthshire, to Tredegar and Sirhowey ironworks, &c.	1802	—	Total 28	To Trevill (with edge-rails), &c. Joins No. 79.	Locom. Eng. and Horses.	30,000 15,000 45,000	..	Chiefly a plate-railway, for iron, coal, &c. Joins the Monmouthshire Canal.
86. South-Eastern	No. 55, at Redhill, 20 m. from London, by Tunbridge and Ashford to Dover.	1836	In progress.	66	Joins No. 55	Locom. Engines intended	1,400,000 450,000 1,850,000	..	For passengers and general traffic. Formerly intended to commence at Croydon.
87. Stockton and Darlington.	From Stockton, by Darlington, to Witton Park Colliery, Durham.	1821	Sept. 1825	Total 54 (*f*)	To Middlesbrough, &c.&c. Joins 5, 20, & 34.	Chiefly Locom. Engines.	82,000 20,000 102,000	450,000 *See* note (*f*).	For coal, merchandize, and passengers. Gauge, 4 ft. 8½ in. Principally a double line.
88. Stratford and Moreton.	Stratford-on-Avon, Warwickshire, to Moreton-in-Marsh, Gloucestershire.	1821	1826	16 Br 2¼	To Shipston-on-Stour.	Horses	33,500 7,000 40,500	77,449	For coal, corn, &c. A few passengers conveyed. A single track.
89. Surrey . .	From the Thames at Wandsworth to Croydon, Surrey.	1801	1805	9¼ Br. 1¼	To Carshalton, &c. Joins No. 23.	Horses	35,000 15,000 50,000	60,000	A plate-railway for coal, lime &c. Gauge, 4 ft. Ordinary inclination, 1 in 120.
90. Taff Vale . .	Merthyr Tydvil to the Port of Cardiff, Glamorganshire .	1836	Part 1840	24¼ Brs. 17	Several, to mines, &c.	Locom. Engines.	300,000 100,000 400,000	620,000	For minerals, merchandize, and passengers. 14 miles opened Oct. 1840.
91. Taw Vale . .	Barnstaple to an intended Dock at Fremington, Devonshire.	1838	In progress.	2¼	..	Locom. Engines allowed.	15,000 5,000 20,000	..	For passengers, merchandize, &c. A tunnel 418 yards long, for one track.
92. Thames Haven	No. 28, at Romford, to the Thames, at Shell Haven, Essex.	1836	Not yet made.	15¼	Intended to join No. 28.	Locom. Engines intended.	450,000 150,000 600,000	..	For coal, merchandize, and passengers. The Company to form docks at Shell Haven.
93. Warrington & Newton . .	Warrington to No. 50 at two points, at Newton, Lancashire.	1829	1833	4¼	Joins Nos. 33 & 50.	Locom. Engines.	53,000 20,000 73,000	93,000	For passengers and general traffic. Gauge, 4 ft. 8½ in. United in 1835 to No. 33.
94. West Durham.	Byer's Green branch of No. 20, to Crook and Billy Row, Durham.	1839	Part 1840	5¼	Joins No. 20	Locom. Eng. One incl. pl.	33,923 11,307 45,230	..	Chiefly for minerals. Commenced before the Act was obtained.
95. West London, formerly Birm., Bris. & Thames Junc.	Nos. 36 and 53, near Holsden Green, to the Canal at Kensington.	1836	In progress.	3	Joins Nos. 36 & 53.	Uncert*. Locom. allowed.	150,000 50,000 200,000	280,000	To connect 36 and 53 with the Thames, by means of the Kensington Canal.
96. Whitby & Pickering.	Harbour of Whitby to Pickering, North Riding of Yorkshire.	1833	May, 1836	24	To Whitby Stone Quarries.	Horses, and two incl. pl.	80,000 25,000 105,000	135,000	For passengers and general traffic. A single track. Gauge, 4 ft. 9½ in.
97. Wigan Branch	No. 50, at Parkside, to the Town of Wigan, Lancashire.	1830	Sept. 1832	7 Br. 3	To New Springs. Joins No. 50; *see* also 72.	Locom. Engines.	70,000 17,500 87,500	..	For passengers and general traffic. Gauge, 4 ft. 8½ in. United in 1834 with No. 72.
98. York & North Midland.	Tanner Row, City of York, to No. 71, at Altofts, West Riding of Yorkshire.	1836	June, 1840	23¼ Brs. 4	Branches to Nos. 48 & 71. Joins also 34.	Locom. Engines.	370,000 123,333 493,333	335,000 111,666 446,666	For passengers & general traffic. Gauge, 4 ft. 9 in. Capital reduced by Act of 1837.

RAILWAYS OF SCOTLAND.

NAME.	COURSE.	Date of Act.	Date of Opening.	Length in Miles.	Branches, &c.	Power used.	Original Capital.	Present Capital.	REMARKS.
99. Arbroath and Forfar.	No. 102, at Arbroath Harbour, to Forfar.	1836	Jan. 1839	15¼	Joins No. 102	Locom. Engines.	70,000 35,000 105,000	160,000	For passengers and general traffic. A single track, Gauge, 5 ft. 6 in.
100. Ardrossan, formerly Johnstone and Ardrossan.	Ardrossan Harbour to Kilwinning, Ayrshire; projected to extend to Johnstone.	1827	Part —	(*g*) 5¼ Brs. 6¼	Two Branches. Joins 109.	Chiefly Locom. Engines.	95,658 in shares.	106,666	For coal, passengers, &c. Gauge, 4 ft. 8½ in.

(*f*) The main line from Witton Park Colliery to Stockton, is 28, or to Middlesbrough, 32 miles; and the total length of the lines specified in the Acts of Parliament is about 40 miles. It appears, however, by a letter from the Chairman to the Irish Railway Commissioners, that the Company have formed 54 miles of railway, of which 28 has a double track. The sum of 450,000*l.* is stated in the same document to have been expended, though the total *Parliamentary* capital is only 252,000*l.*

(*g*) This railway, as projected, was 22¼ miles long, but only 5¼ miles of the main line were completed. This part was worked by horses till 1840, when the capital was increased, and the line adapted to locomotive engines.

NAME.	COURSE.	Date of Act.	Date of Opening.	Length in Miles.	Branches, &c.	Power used.	Original Capital.	Present Capital.	REMARKS.
101. Ballochney .	Arbuckle and Ballochney to No. 111, at Kippbyres, Lanarkshire.	1826	1828	4½ Brs. 2	Several, to collieries. Joins 111 and 116.	Chiefly Locom. Engines	£18,425 10,000 28,425	£93,333	For coal, ironstone, &c. Some passengers conveyed. Gauge 4 ft. 8½ in.
102. Dundee and Arbroath.	Trades Lane, Dundee, by the coast, to No. 99, at Arbroath Harbour.	1836	April, 1840	16¾	Joins No. 99	Locom. Engines	100,000 40,000 140,000	..	For passengers and general traffic. Gauge, 5 ft. 6 in. Part opened in 1838.
103. Dundee and Newtyle.	North side of Dundee to Newtyle, county of Forfar.	1826	Dec. 1831	10½	Joins Nos. 112 and 113.	Locom. & fixed Engines	30,000 10,000 40,000	170,000	For passengers and general traffic. A single track. The line rises 544 feet.
104. Edinburgh and Dalkeith.	Edinburgh, by Dalkeith, to the South Esk, near Newbattle.	1826	1831	Total 15	To Leith, Fisherrow, &c.	Horses.	70,125 20,000 90,125	208,753	For coal, merchandise, and passengers. Chiefly a single track.
105. Edinburgh and Glasgow.	The Haymarket, Edinburgh, to North Queen Street, Glasgow.	1838	In progress.	46 Br. 1	To Falkirk, for horse power.	Locom. Engines intended	900,000 300,000 1,200,000	..	For passengers and general traffic. Gauge, 4 ft. 8½ in.
106. Edinburgh, Leith, and Newhaven.	Princes Street, Edinburgh, to Trinity Harbour.	1836	In progress.	2½	To Leith, abandoned by Act of 1839.	Fixed Engines intended	100,000 40,000 140,000	..	For passengers, goods, &c. A tunnel 1000 yards long, 12 ft. wide, and 16 ft. high.
107. Garnkirk and Glasgow.	No. 111, at Cargill Colliery, by Garnkirk, to Glasgow.	1826	1831	8¼	Joins No. 111.	Chiefly Locom. Engines.	28,497 10,000 38,497	169,195	For the conveyance of coal, passengers, &c. Gauge, 4 ft. 8½ in.
108. Glasgow, Paisley, and Greenock.	Near Glasgow Bridge, Glasgow, through Paisley, to Greenock.	1837	Part 1840	*22½	To quays, &c. Joins No. 109.	Locom. Engines.	400,000 133,333 533,333	..	For passengers and general traffic. Gauge, 4 ft. 8½ in. *6½ m. joint line with 109
109. Glasgow, Paisley, Kilmarnock, and Ayr.	Glasgow to Paisley, by No. 108, and thence by Kilwinning to Ayr.	1837	Part 1840	*40 Brs. 17½	To Kilmarnock, &c. Joins 100, 108, and 110.	Locom. Engines.	625,000 208,000 833,000	..	For passengers and general traffic. Gauge, 4 ft. 8½ in. * 6½ m. joint line with 108.
110. Kilmarnock and Troon.	Kilmarnock to the Harbour of Troon, Ayrshire.	1808	—	9½	Joins No. 109.	Horses.	40,000 15,000 55,000	95,000 See note (*h*).	A plate railway for coal, lime, &c. Very few passengers. Gauge 4 ft. See note (*h*).
111. Monkland and Kirkintilloch.	Palace Craig, Old Monkland, Lanarkshire, to near Kirkintilloch.	1824	1826	12	To collieries, &c. Joins 101, 107, and 117.	Locom. Engines.	32,000 10,000 42,000	204,000	For coal, &c. A few passengers conveyed. Joins the Forth and Clyde canal.
112. Newtyle and Coupar Angus.	No. 103 at Newtyle, to Coupar Angus, Forfarshire.	1835	Feb. 1837	5½	Joins Nos. 103 and 113.	Horses.	15,200 5,000 20,200	40,200	For passengers and general traffic. Worked by No. 103 company.
113. Newtyle and Glammiss.	Nos. 103 and 112 at Newtyle, to Glammiss, Forfarshire.	1835	—	..	Joins Nos. 103 and 112.	..	20,000 6,600 26,600	..	For passengers and general traffic.
114. Paisley and Renfrew.	Paisley to the River Clyde at Renfrew Ferry.	1835	April 1837	3½	..	Locom. Engines.	23,000 10,000 33,000	..	For passengers to steam-boats, &c., and general traffic.
115. Polloc and Govan.	Collieries at Polloc and Govan to the Clyde at Broomielaw.	1830	—	..	To Rutherglen, &c.	..	10,000 5,000 15,000	66,000	For the conveyance of coal, &c. Gauge 4 ft. 8½ in.
116. Slamannan.	No. 101 at New Monkland, to the Union Canal near Linlithgow.	1835	1840	12½ Br. 4½	To Bathgate, &c. Joins No. 101.	Locom. Engines.	86,000 20,000 106,000	186,666	Chiefly for minerals. A few passengers. Partly a single line. Gauge 4 ft. 8½ in
117. Wishaw and Coltness.	No. 111 at Old Monkland, to Chapel, parish of Cambusnethan, Lanarkshire.	1829	6½m. open.	13	To collieries. Joins No. 111.	Chiefly Locom. Engines.	60,000 20,000 80,000	160,000	For minerals, &c. Part still in progress. Gauge 4ft. 8½ in.

RAILWAYS OF IRELAND.

NAME.	COURSE.	Date of Act.	Date of Opening.	Length in Miles.	Branches, &c.	Power used.	Original Capital.	Present Capital.	REMARKS.
118. Belfast and Cavehill.	Stone Quarries at Cavehill, to Belfast Harbour.	1832	Sept. 1840	2	..	Locom. Engines allowed.	£7,500 2,500 10,000	£38,200	For the conveyance of stone, &c. Gauge 4 f. 8½ in.
119. Cork and Passage.	City of Cork, to Passage, entrance of Cork Harbour.	1837	..	6½	..	Locom. Engines allowed.	200,000 66,000 266,000	..	To convey passengers to a steam-packet pier. Not in progress, November, 1840.
120. Dublin and Drogheda.	Custom-House Quay, Dublin, near the Coast, to Drogheda.	1836	In progress.	32	..	Locom. Engines intended	600,000 200,000 800,000	450,000 150,000 600,000	For passengers and general traffic. Capital reduced by an Act passed 1840.
121. Dublin and Kingstown.	Westland-row, Dublin, to Kingstown Harbour.	1831	Dec. 1834	5⅝	..	Locom. Engines.	200,000 70,000 270,000	..	For passengers and general traffic. Gauge 4 f. 8½ in
122. Dundalk Western.	Dundalk, county of Louth, to Ballaby, county of Monaghan.	1837	..	24	..	Horses intended	100,000 32,000 132,000	..	For passengers and general traffic. Works commenced in May, 1839.
123. Great Leinster and Munster.	Dublin, by Naas, Athy, and Carlow, to Kilkenny	1837	In progress.	73½	..	Locom. Engines intended	800,000 265,000 1,065,000	..	For passengers and general traffic. The land required agreed for in 1840.
124. Ulster.	From near Durham Street, Belfast, by Lisburn and Portadown, to Armagh.	1836	Part 1839	36	..	Locom. Engines.	600,000 200,000 800,000	..	For passengers and general traffic. 8 miles open, and a further portion in progress.

(*h*) An Act passed in 1837, but which appears not to have been carried into effect, allows the raising of 40,000*l*. by new shares, for converting this line into an edge-railway for locomotive engines.

American Railways.

The first railway constructed in the United States of America was a line of about four miles, for the conveyance of granite from the quarries at Quincy to Boston harbour, which was opened in 1827. The successful introduction of steam locomotion in England was immediately followed by the formation of numerous important lines of railroad in America, and this species of enterprise has been so greatly encouraged, that, according to a statement published by the Chevalier de Gerstner (an engineer celebrated for the promotion of railways on the continent of Europe), the railroads completed in the United States, down to the summer of 1839, amounted to more than 3000 miles, while the extent of those in progress warranted an expectation that about 3100 miles would be in operation by the close of that year. In many cases the country over which these lines have been made is favourable in a degree unparalleled in this country; and, owing to the cheapness of land and timber, the great facilities afforded by the various states, and the comparatively slight construction of many lines, their average cost has been greatly below that of English railways. Stevenson, in his 'Civil Engineering of North America,' states the average of several lines to be about 4942*l.* per mile, a statement which appears to be borne out by the more recent calculation of Gerstner. Many lines are laid with but one track, and the gradients and curves are often less favourable than those of the public lines in this country, the thin population of the districts passed through, and the high price of labour, precluding much expense in cuttings and embankments. Timber is used extensively in the construction of the permanent way, on account of the facility of working it, and the expense of stone and iron. Stone blocks have been found in some instances to split from the effect of the intense frost, which forms an additional reason for the preference given to wood. The gauge most commonly adopted is four feet eight inches and a half, this width having been taken from the English lines. American locomotive engines do not usually travel so fast as those made by British manufacturers, but they are frequently adapted for ascending steep inclined planes, and, as described in a previous page, for traversing curves of small radius. The carriages used are very large and commodious, some being as much as fifty or sixty feet long, mounted on eight wheels, and so arranged that passengers may walk from one end of the train to the other.

According to Stevenson, the only railway in the British dominions in North America, down to the year 1837, was the Champlain and St. Lawrence line, which was formed under an Act passed in 1832. It is about sixteen miles long, and is worked by locomotive engines.

A railway of between forty and fifty miles, for the conveyance of passengers and goods by locomotive engines, has been made in the island of Cuba, between Havana and Guines. The rails, engines, carriages, &c. were made in England.

Continental Railways.

The first railway laid down in France was a short line formed in 1783 at Mont Cenis, for the use of the foundries of Creusot. In 1823 a line of about twelve miles was completed between St. Etienne and Andrezieux, and others uniting it with Lyon and Roanne have since that time been brought into operation, partly worked by locomotives and partly by horses. Though useful, they have not proved remunerative. Preliminary measures have been taken for several important lines, but comparatively little has been done in their formation. Railways are open from Paris to Versailles and St. Germain, and a second line to Versailles and one to Orleans are in progress. The Paris and Rouen railway, which will probably be extended to Hâvre, is about to be formed by a company composed of French and English capitalists.

In Belgium a comprehensive system of railways is in course of execution by the government. The scheme was sanctioned by the legislature in 1834, and the first section of railway was opened in the following year. The aggregate length of the lines comprised in the original plan was nearly 240 miles; but subsequent additions have increased the total length to upwards of 400 miles, of which 230 miles were in use in March, 1840, and the remainder was expected to be complete within two years of that time. Of the lines now completed, about three-fourths have but a single track, and, the country being generally flat, the expense has been small in comparison with the railways of England, not having exceeded 10,000*l.* per mile, including engines and carriages. The average speed is equal to that on the English lines, and the amount of travelling has been very great, although the returns are small, the object of the government being rather to provide accommodation at the lowest possible charge, than to make the railways a source of revenue. The main line from west to east extends from the port of Ostend to Liége, and thence to the Prussian frontier, to join the railway to Cologne. Another line commences at Antwerp, and, intersecting the former at Malines, proceeds to Brussels and Mons, whence it is to extend to the frontier of France. Branches connect Namur, St. Trond, Courtrai, Tournay, &c. with the main lines, and afford facilities for communication with the projected lines of the neighbouring countries.

In Germany a railway of about 130 English miles, between Budweis, Linz, and Gmunden, has been in operation several years, part having been opened as early as 1828. It is worked by horses, and used chiefly for the carriage of merchandise. Other lines of great extent, generally for the use of locomotive engines, are in progress, and considerable portions are in successful operation. The Austrian government has afforded great encouragement to these undertakings, which will shortly connect Vienna with the surrounding countries. Important railways are also in progress in Italy and other parts of the continent of Europe.

In Russia an interesting line of about seventeen English miles, connecting St. Petersburg with the towns and royal parks of Pawlowsk and Zarscoe-Selo, was completed in 1837. It is worked by locomotive engines, and is traversed by a great number of passengers. The line has but one track, six feet wide, and was formed by a joint-stock company under imperial sanction. It is intended to continue the line to Moscow, about 420 miles from St. Petersburg, and some other extensive railways are in contemplation.

Railways have been introduced into Egypt, and projected in India and several other parts of the world, the engineers being frequently and the machinery almost invariably from England.

RAIMONDI, MARC ANTONIO, commonly called by his baptismal names Marc Antonio only, was born at Bologna about the year 1487 or 1488. He was instructed in the art of design by Francesco Maria Raibolini, known as Francesco Francia, but having seen some prints by Albert Dürer, he determined on adopting engraving as a profession. It does not appear by whom he was instructed in that art, though most probably it was by some goldsmith, for his first essays with the graver were the embellishment of silver ornaments worn at that period, a circumstance that seems to have led M. Ponce, in the 'Biographie Universelle,' to state that Marc Antonio was originally intended for that business. One of his earliest engravings on copper was a plate from a picture by Francia, representing Pyramus and Thisbe, dated 1502, and executed, with some others, it is supposed, after the same artist, before Raimondi's departure from Bologna. At Venice, whither he removed, he purchased, with all the money he had taken with him from home, a set of thirty-six prints engraved on wood by Albert Dürer, representing the Life and Passion of our Saviour. Charmed with the correctness of the design and the precision of the execution, he imitated them on copper, according to Vasari, with such exactness, that they sold in Italy for the originals. The same authority states that Dürer, having seen one of them at Nürnberg, complained to the senate at Venice of the fraud that had been practised, and that Marc Antonio was forbidden to use his signature, which was the only redress he could obtain. It seems that Vasari must have fallen into an error in this story, and mistaken the Life of our Saviour for the Life of the Virgin, as Marc Antonio copied both sets from the cuts of Albert Dürer, to the latter and not to the former of which he affixed the mark of that great artist. M. Heinecken also points out that, besides the tablet which Dürer used as his mark, Marc Antonio added within it his own initials joined, and that he also used the tablet without any mark at all. Indeed there seems altogether very little probability in the story told by Vasari. Persons acquainted with the subject of engravers' monograms are aware that the tablet of the peculiar form adopted by these two great rivals, namely, an oblong square with a small arched piece on the centre portion of the top, was a favourite mark of many artists, as may be seen on the works of Van Assen, Dolendo, Krugen, Sadeler, and Vogtherr. After quitting

Venice, he proceeded to Rome, where he was soon noticed by Raffaelle, who employed him in engraving from his designs, and, it is said, in some instances even traced the outlines on the plates, that the correctness of the drawing might be more perfectly preserved. His first plate after Raffaelle was the Death of Lucretia, which is neatly engraved, but is not one of his best works. His next print, after the same master, was a Judgment of Paris, executed in a more bold and spirited style. These were followed by many more, and amongst them the Murder of the Innocents, after Raffaelle, who was so perfectly satisfied with the efforts of the engraver, that he sent many specimens of his works as complimentary presents to Albert Dürer himself, by whom they were thought well worthy of acceptance.

After the death of Raffaelle, which occurred in 1520, Giulio Romano engaged Marc Antonio to engrave from his designs. Amongst these works are a set of disgusting plates of subjects for which Aretino composed the verses, and which so greatly excited the indignation of Pope Clement VII., that he ordered the engraver to be thrown into prison, from which he was only released at the earnest intercession of some of the cardinals and of Baccio Bandinelli. Moved by gratitude for the services of Bandinelli, Marc Antonio engraved his celebrated print of the Martyrdom of St. Lawrence from a picture by him, which, besides greatly conducing to the engraver's high reputation, procured him not only the entire pardon of the pope, but his active protection and support. On the sacking of Rome by the Spaniards, in 1527, he was obliged to fly, having lost all he had acquired by his art. He returned to his native place, where he continued to engrave until the year 1539, which is the date affixed to his last plate, representing the Battle of the Lapithæ, after Giulio Romano. He is said by Malvasia to have been assassinated by a Roman nobleman for having, contrary to his engagement, engraved a second plate of the Murder of the Innocents, from the design of Raffaelle.

This engraver may be considered one of the most eminent artists in that branch that has ever appeared. His outlines are pure; the character and expression of his heads beautiful; whilst the exact and correct drawing of his works, particularly in the extremities of his figures, evidence that he was in all respects a complete master both of drawing and design. He was one of the first Italian engravers of distinction. The high reputation of Raffaelle, and the happy chance which conduced to the engagement of Marc Antonio as the engraver of his chief works, contribute as well to his reputation as to the high value which is ever set upon his engravings, and the great price they always obtain. Berghem paid sixty florins for an impression of his Murder of the Innocents; and one of Saint Cecilia was sold at the sale of St. Yves for six hundred and nineteen francs. M. Ponce has given the date of his death as 1546; but M. Heinecken seems to consider that the date upon the Battle of the Lapithæ was about the period at which he ceased to work. Some of his prints are marked with an A. and an M. joined, and others with M. A. F. also joined, the F. being used in consequence of the cognomen La Francia having been given to him from his successful study under Raibolini; and some are marked with the tablet mentioned by M. Heinecken.

The works of Marc Antonio are exceedingly numerous. A very copious catalogue of them is given in the work of the last-named author, which extends to a hundred and twenty-five pages. Mr. Bryan observes, that in the prints of this eminent artist great attention should be paid to the different impressions of the plates, which have been greatly retouched and altered by the different printsellers through whose hands they have passed. The best impressions are without the name of any publisher. After the plates were taken from the stock of Tommaso Barlacchi, they came into the possession of Antonio Salamanca; afterwards they passed through the hands of Antonio Laferri, from thence to Nicholas van Aelst, and lastly became the property of Rossi, or De Rubeis, at a time when they were nearly worn out.

In the Print Room of the British Museum there is a very fine collection of the works of Marc Antonio. They amount to about five hundred, the whole of his labours enumerated by Bartsch being six hundred and fifty-two; but it must be recollected that the works of two of his principal pupils, Agostino Veneziano and Marco da Ravenna, are counted with them. Amongst those of the greatest rarity are the Transgression of Adam and Eve; David cutting off the head of Goliah, before the monogram of Marc Antonio was added, a copy of which produced 45*l.* at the sale of the late Sir M. M. Sykes, Bart., in 1824; the Madonna lamenting over the dead body of Christ, called 'La Vierge au bras nud,' from the circumstance of having one arm naked, a print of much value, a copy of which fetched at the same sale 25*l.*, whereas the other print of the same subject, which has the arm draped, engraved also by Marc Antonio, produced only 2*l.*; the Massacre of the Innocents, with the chicot tree; the Martyrdom of St. Lawrence, a subject mentioned above, a first impression with the two forks, of the estimated value of a hundred guineas, a very inferior copy of which, as to condition, produced at the above sale 46*l.*; the Pest, a print taken before the letters were engraved, of which only three copies are known to exist; and the Dance of Cupids, a small plate, which, if in good condition, is valued at 60*l.*, a copy of which sold at the sale before alluded to for 57*l.*

There does not appear to be any certainty as to the exact time of the birth of Marc Antonio. M. Heinecken observes that Vasari alone has given us any notice of him. Borghini, Malvasia, and Baldinucci, as well as all the later writers, draw from Vasari all that they say. None of them mention either the year of his birth or death. If however the piece representing Apollo and Hyacinth was engraved by him in 1506, at the age of nineteen years, as the signature would seem to indicate, for the nine only is legible in the impression in the Imperial collection at Vienna, we may infer that he was born at Bologna in 1487 or 1488. (Heinecken, *Dict. des Artistes*; *Biographie Universelle*; Strutt's and Bryan's *Dictionaries*; Bartsch, *Le Peintre Graveur*.)

RAIN. The antients appear to have been very imperfectly acquainted with the constitution of the atmosphere, and Descartes is probably the first who, in attempting to refer meteorological phenomena to their causes, has approached near the hypotheses now generally received: for he ascribes the formation of clouds, snow, rain, and hail to variations of temperature in the upper regions of the air. He supposes that when the coldness in any portion of those regions becomes intense, the subtle matter disseminated among the particles of vapour becoming too weak to keep those particles at a distance from one another, the latter must rush together, and either form small spicular filaments or spherical drops of ice. The superficies of these filaments or drops being supposed to be considerable when compared with their volumes, he conceives that the resistance of the air may be great enough to prevent them from descending by their weight, and that thus a great assemblage of them may remain suspended in the form of a cloud above the earth. The filaments becoming by an accession of heat partially liquefied, it may happen that many of them will adhere together, and thus form flakes of snow, which, at length acquiring sufficient weight to overcome the resistance of the air, descend to the ground. In order to explain the origin of rain and hail, he supposes that the flakes, arriving near the surface of the earth, may pass through a warmer region than that in which they were formed, and there dissolving, they assume the figure of spherical or spheroidal drops of water. Again, if in the descent the latter should meet a current of cold air, they become globules of ice. (*Meteora*, cap. v., vi.)

The diffusion of the electric fluid through the earth and atmosphere has led some meteorologists to believe that the variations in its quantity or intensity in particular regions may be the cause of the formation of snow, rain, and hail. The electrical particles, being endowed with a great repulsive power, are supposed to keep in general the particles of vapour asunder; and when, from any cause, some given volume of air is deprived of its natural quantity of electricity, these particles unite by their mutual attractions, and thus form drops of rain or ice. From the showers which accompany a thunder-storm, there is no doubt that electricity co-operates in some measure in the production of rain; and it may be remarked in support of the above hypothesis that rain is most abundant among mountains, their elevated summits being favourable for receiving and discharging electricity, while in some regions where thunder is little known there is also little rain.

But the theory first proposed by Dr. Hutton of Edinburgh (*Phil. Trans.*, Edin., 1784) is that which appears to correspond most satisfactorily to the observed phenomena of the atmosphere; and accordingly it has been adopted by nearly every distinguished meteorologist since that time. This theory will be briefly described.

The atmosphere surrounding the earth is known to consist of air and aqueous gas or vapour, both of which are elastic; and according to the experiments of M. Gay-Lussac, the elasticity of the vapour is equal to that of the air at an equal temperature, both when the vapour exists alone, and when it is combined with the air; hence it is inferred that in the atmosphere the vapour and air are in mechanical union only, and also that the particles of the former have the power of moving freely in the intervals between those of the latter. The atmosphere is supplied with humidity by evaporation from the waters of the earth, and its power to hold the water in solution depends on its temperature, an increase of the latter augmenting that power, and a decrease diminishing it: but in the theory of Hutton, the diminution of the power takes place in a higher ratio than the diminution of the temperature.

Now the quantity of moisture in the atmosphere will at all times be nearly equal to the greatest quantity that can be maintained in it in a state of vapour at the existing temperature. Therefore if two volumes of air thus saturated with moisture, but of different temperatures, become by any means mixed together, a mean degree of heat results from the union; but the whole quantity of moisture in the sum of the volumes of air will, agreeably to the theory, be greater than that which is due to the mean temperature, and the excess will of course be condensed or precipitated. The vapour so condensed forms a cloud; and if this be specifically heavier than the air in which it is formed, it will begin to sink. Should the atmosphere near the earth be less dense than the cloud, the latter will continue to descend till it touches the ground, when the aqueous particles, if small, will form what is called a mist; or if large, and particularly if the condensation of the vapour has been rapid and copious, they will descend by their gravity in rain, snow, or hail, according to the temperature of the region through which they pass. It may happen however in the descent that a cloud arrives in a warmer region than that in which it was formed; in this case the condensed moisture may again become vapour, and the cloud may re-ascend to a region at which a new condensation takes place. But though it be true that some precipitation must follow, whatever be the difference between the temperatures of the two volumes of air, yet unless the mean of the two quantities of vapour should be greater than the quantity necessary for complete saturation at the mean of the two temperatures, the precipitation will not be perceptible in the form of rain.

In order to illustrate the general subject of clouds and rain, Mr. Daniell, in his 'Essays on the Constitution of the Atmosphere,' supposes, first, that the earth is a sphere of uniform temperature, and surrounded by an atmosphere of dry and permanently elastic fluid; and he shows that on this supposition the density of the air would diminish in a geometrical progression at elevations increasing by equal increments. He observes also that the temperature would decrease with the densities, and that the atmosphere would be constantly in equilibrio. This would continue to be the case if the general temperature of the sphere were to be increased, provided that increase were uniform at all points on its surface. Now, if the temperature of the sphere, instead of being uniform, were supposed to increase from the poles towards the equator, the unequal densities produced in vertical columns of the air by the differences of temperature at equal heights above the surface of the sphere, would give rise to lateral pressures which, in the lower strata, would produce currents tending from the poles towards the equator; but the elasticity of the air, which is constant near the surface of the sphere, varies with the height above that surface, according to such a law that, beyond a certain elevation, it would produce lateral pressures exceeding those which arise from the density in the neighbouring columns at equal altitudes, and thus there would arise a current in the upper regions flowing continually from the equator towards the poles.

He supposes next that the sphere is covered with water everywhere of equal temperature, and is surrounded by an atmosphere of pure aqueous vapour; and he shows not only that the density of this vapour would diminish upwards according to the law before mentioned, but that the atmosphere would in this case also be in equilibrio and transparent even when the general temperature of the sphere experienced a uniform increase. But if the temperature of the sphere were to increase as before, from the poles towards the equator, the density and elasticity of the vapour varying also with the temperature, there would arise by evaporation at the equator a current tending from thence to the poles, and this, being condensed in its course, would return from the poles towards the equator in the form of water. The condensation thus going on would cause the atmosphere to be constantly charged with clouds and rain. Unless however the excess of temperature at the equator were maintained by some foreign power, as solar radiation, the temperature over the whole sphere would by degrees become equalized; the equatorial parts becoming cooled by evaporation, while the polar regions would become warmed by the condensation.

Mr. Daniell afterwards contemplates an atmosphere consisting of a permanently elastic fluid mixed with aqueous vapour, and surrounding a sphere of water of uniform temperature; and he observes that, since the evaporation would be slow, the small quantity of water precipitated would be almost immediately dissolved by the superior temperature of the stratum below, into which it would tend to fall; therefore this atmosphere would be free from clouds. But in the event of the temperature of the sphere increasing from the poles to the equator, the evaporation in the latter region would destroy the regular gradation of temperature in the atmosphere from the surface of the sphere upwards; the evaporated water rising to the middle regions would there, in consequence of the diminished temperature, give out its latent heat, and become condensed; then, descending, it would acquire from below a new portion of heat, with which it would rise till it was again forced to part with its caloric. This process may be supposed to continue till those regions of the atmosphere become saturated with vapour, and at the same time rarified by the heat. The rarefaction of the air would diminish its resistance to the general movement of the vapour towards the poles, and thus the vapour would rush with force in those directions; but on arriving in latitudes at which the temperature is too low to allow the air to hold it in solution, condensation would take place, and clouds would be formed.

The circumstances just mentioned correspond nearly to those which would take place about the earth if local and other accidental circumstances did not interfere with the general process. In its actual condition, when a column of air vertically over any place is from any cause heated more than the neighbouring columns, it begins to ascend by its diminished specific gravity, the colder air of the vicinity flows in to fill up the void, and thus the relation between the temperature and humidity at the place is deranged. Then, agreeably to the general theory of Dr. Hutton, a precipitation of the vapours takes place.

In proportion to the density of the vapour, the magnitudes of the condensed particles of water are greater; in the upper regions of the air the cloud assumes a light appearance, but below it is more dark. After their formation, the clouds are driven about by the winds, receiving new accessions of precipitated vapour till the air is no longer capable of supporting them, and then their substance descends in rain, snow, or hail.

On the supposition that the surface of the earth is without inequalities, and that the temperature gradually diminishes from the equator towards either pole, it should follow that the rarefaction of the air and the evaporation of the water, and consequently the quantity of rain, must diminish according to some law with the distances of places from the equator. Now the mean temperature in any latitude being known, the quantity of moisture in the atmospherical column at that latitude can be found, since it depends on the temperature; hence knowing also the variations to which the temperature of the atmosphere at the place is subject in the course of the year, the mean annual depth of rain in that latitude may be computed. On such principles Humboldt has determined that the mean annual depth of rain should be, at the equator, 96 inches; in lat. 45°, 29 inches; and in lat. 60°, 17 inches. The circumstances however which render the temperature in different latitudes, and even on the circumference of the same parallel, irregular, must produce irregularities in the quantities of rain which fall at different places; yet the results of observation show that, in proceeding from the equator towards the north pole, there is in reality a diminution in the mean annual quantities of rain.

From an average of the observations made during fourteen years (1810 to 1823 inclusive), the mean annual depth of rain on the Malabar coast is 123.5 inches, and the mean annual temperature is 80·4° (Fahrenheit), but the annual depths of rain are very irregular and differ considerably. From a mean of observations for seven years (1817 to 1823 inclusive), the mean annual depth of rain at Bombay was only 85·24 inches. From a mean of observations during seventeen years (1802 to 1818 inclusive), Mr. Dalton makes the mean annual depth of rain at Manchester equal to 33·596 inches, the mean annual temperature being 47·6°; and here also the annual quantities of rain vary very irregularly. The same meteorologist estimates the average of the annual quantity of rain in England to be 31·3 inches; the greatest quantity being at Keswick in Cumberland (=67·5 inches), and the least at Upminster in Essex (=19·5 inches); but it is supposed that this estimate of the mean quantity is higher than the truth, because too many of the observations were made in the maritime counties, where the atmosphere may be expected to be the most humid. In regions where the trade-winds blow constantly, rain seldom falls; and the reason may be, that both the temperature and the currents of air being there nearly uniform, the vapours raised from the ocean are carried about the earth without suffering those partial accumulations by which condensation and precipitation might be produced. But elsewhere the irregular distribution of land and water, the existence of mountain-chains, and even the various capacities of different parts of the earth's surface for absorbing or communicating heat, independently of variations in the electricity of the air, are to be considered as the most frequent causes of perturbation in the general currents of the atmosphere, and consequently of the fall of rain.

The dense mists which rest on the ocean near Newfoundland are precipitations caused by inequalities in the temperature of the ocean in the line of the *Gulf-stream*. In the year 1821, in consequence of very strong winds between the tropics during the summer having caused an extraordinary difference between the levels of the waters in the Gulf of Mexico and those of the Atlantic Ocean, the stream of warm water was found to extend eastward of the Azores; and it deserves to be remarked that this unusual circumstance was attended, both in France and in England, by a very hot and damp winter, together with an excessive fall of rain. (Sabine, *Experiments on the Figure of the Earth*, 1825.) The rains which frequently deluge the tropical islands are in part produced by the volumes of air which are intermingled by the sea and land breezes; and those which fall at the time of the summer solstice in Africa may be ascribed to the immediate precipitation of the vapours which flow from the seas to supply the place of the rarefied air above the heated lands; while the drought which prevails in the sandy deserts of that quarter of the earth is explained by the level character of those deserts, over which the currents of air may be supposed to flow nearly without interruption.

From April to October, the winds blowing from the south-west towards the coast of Malabar are accompanied by heavy rains, and the circumstance may be accounted for by the vapours of the ocean being brought from a warm region to one which is less so, and consequently becoming there condensed and precipitated. On the other hand, the prevailing winds on the coast of Peru, being from the south and south-west, come from a cold to a warmer region; consequently a diminution of the degree of saturation must there take place, and the vapours remain suspended; accordingly it is found that rain seldom falls on that coast. The clouds which overhang the coast of Malabar during the monsoon above-mentioned are arrested by the chain of the Ghauts, and while it rains on the western side the fair season is enjoyed on the coast of Coromandel. Again, the currents of air which pass over Peru, in crossing the chain of the Andes, where the temperature is lower, become condensed by the cold, and the rain is there precipitated in abundance. The vapours which come from the Atlantic ocean, and pass over the south-western counties of England, must be more abundant than those which arrive there from the continent of Europe; and from observations made at Penzance, the rains which accompany the westerly winds at that place exceed those produced by the easterly winds in the ratio of about three to one.

In tropical regions the quantities of rain which fall in different months of the same year are very unequal: at Bombay the mean monthly depth in June was found to be 24 inches, and in October, 1·26 inches. In temperate climates the quantities differ much less, but more rain falls during the second half year than during the first. The means of observations continued during 40 years at London give, for the depth of rain from January to July inclusive, 8·539 inches, and from July to December inclusive, 12·147 inches.

In general the lowest stratum of air about the earth contains the greatest quantity of water in solution; and hence it might be expected that more rain should fall on low level plains than in elevated countries. The contrary however is the fact: and this may be accounted for by the variety of currents among mountains, and by clouds resting frequently on the summits of hills without descending to the plains. While the average annual depth of rain at Keswick is 67·5 inches, in the interior of the country and on the sea-coast it is but 25 inches: and while the average depth on the St. Bernard is 63·13 inches, that at Paris is 20 inches only. Yet, from the observations of Dr. Heberden, Mr. Howard, and M. Arago, it appears that the depth of rain on the level of the ground is greater than at the top of a building. The first of these philosophers found that the annual depth at the top of Westminster Abbey was 12·099 inches, while at a lower level, on the top of a house in the neighbourhood, it was 18·139 inches; and on the ground, in the garden of the house, it was 22·608 inches. M. Arago observed, from observations during twelve years, that on the terrace of the Observatory at Paris the annual depth was 50·471 centimetres (19·88 inches), while in the court of that building, which is 28 metres (30 yards) lower, the annual depth was 56·371 centimetres (22·21 inches).

Mr. Howard has observed that, in this country, when the moon has south declination there falls but a moderate quantity of rain, and that the quantity increases till she has attained the greatest northern declination; and on some such results of observation the popular opinion that there is a connection between the alternations of rain and fair weather and the changes of the moon may be founded. Our knowledge of the variations to which the temperature of the air is subject, is however yet too imperfect to allow much dependence to be placed on predictions relating to the weather which are formed from the moon's phases, or even from variations in the state of the barometer or hygrometer.

RAIN, FOSSIL. Singular as may appear the notion that the impressions of rain should be recognisable and be recognised on the surfaces of stratified rocks, the opinion is held by some eminent geologists, on the evidence of specimens of new red-sandstone taken from the Storeton Quarries near Liverpool. In March, 1839, Mr. Cunningham, to whose researches in the Storeton quarries we are indebted for much of our knowledge of the foot-prints of Cheirotheria and other antient animals, communicated a paper on the subject to the Geological Society of London. 'In examining some of the slabs of stone extracted at the depth of above 30 feet, Mr. Cunningham observed that their under surface was thickly covered with minute hemispherical projections, or casts in relief, of circular pits in the immediately subjacent layers of clay. The origin of these marks, he is of opinion, must be ascribed to showers of rain, which fell upon an argillaceous beach exposed by the retiring tide, and their preservation to the filling up of the indentations by sand. On the same slabs are impressions of the feet of small reptiles, which appear to have passed over the clay previously to the shower, since the foot-marks are also indented with circular pits, but to a less degree, and the difference Mr. Cunningham explains by the pressure of the animal having rendered these portions less easily acted upon.' If these impressions on the clay be really the marks of rain or hail (a specimen is before us, and it certainly resembles such impressions on clay), perhaps the easiest way of comprehending the preservation of them is to suppose dry sand drifted by the wind to have swept over and filled up the foot-prints, rain-pits, and hollows of every kind which the soft argillaceous surface had received. (*Geological Proceedings*, 1839.)

RAIN-GAUGE, a vessel for measuring the quantity of rain which falls on any particular part of the earth's surface, the quantity being indicated by the depth of the precipitated water which would cover the ground about the spot, supposing the ground to be horizontal and that the water could neither flow off nor penetrate into the soil.

In order to ascertain the quantity of rain which has fallen during the continuance of a shower, it might suffice to place a prismatical or cylindrical vessel, open at the top, in a horizontal position on the ground or on the top of a build ask will, when the shower has ceased, to measure the depth of the water in the vessel by a scale of inches. But, unless the depth were ascertained immediately, a portion of the water would be carried off from such a vessel by evaporation, and the measure would be less than it ought to be. The difficulty also of ascertaining the true amount of a small depth of water would render the instrument of no practical use. For the purpose therefore of obtaining a more correct estimate of the quantity of rain, it has always been the practice to receive the water in a second vessel, or in a tube, the area of whose horizontal section is less than that of the first, so that the height of the column may be greater. And, since the heights of equal quantities of water in two prismatical or cylindrical vessels are inversely proportional to their bases, it is easy to perceive how a rod may be graduated so as to show, in inches, the depth of water in the upper vessel, and consequently the depth which would have lain on the ground if no absorption had taken place.

Originally this instrument, which has been called indifferently udometer (*udor* and *metron*), pluviometer (*pluvia*), and ombrometer (*ombros*, rain), was nothing more than a prismatical box, having a square base, open at the top and communicating with a prismatical box, placed vertically under it, by means of a pipe open at both ends; the area of a horizontal section of the lower box being, for the reason above given, less than that of the upper box. But it is evident that a prismatical or cylindrical vessel must retain, by adhesion to its sides and bottom, a sensible portion of the water which enters it; and consequently the depth measured in such vessel must indicate a quantity of rain less than that which has really fallen; it has therefore been customary of late to make the upper part of the vessel in the form of a funnel, or inverted cone.

The most general construction of a rain-gauge is shown in the subjoined diagram, which represents a vertical sec-

tion of the instrument. The part CDE is a conical funnel, open both at top and bottom, and the lower extremity enters into the cylinder FG below, which thus receives the rain from the funnel. The rod AB passes through a perforation in a bar CD (in the direction of a diameter of the base at its upper surface), and is attached, at B, to a circular piston, which has nearly the same diameter as the interior of the cylinder: the weight of the piston and rod is such as to allow the former to float with its upper surface on a level with the surface of the water; and the graduations, which are numbered towards B, commence from a point a on a level with the upper surface of the bar CD, when the piston B touches the bottom of the cylinder. A rim, of a cylindrical form, rises a little way above the upper extremity of the conical part of the funnel, in order to prevent the rain-water, which would strike the interior of the latter near that extremity, from being thrown out in consequence of the shock.

The diameter of the funnel at the top may be 12 inches, and that of the cylinder six inches; in which case the area of the horizontal section on which the rain falls will be to that of the cylinder in the ratio of four to one. Hence a depth of water equal to one inch at the horizontal section will be expressed by a space equal to four inches on the length of the rod; and, each of such spaces being divided into 100 parts, the depth of water at the said section will be indicated in hundredths of an inch. The height of the cylindrical vessel below the funnel may be from 25 to 30 inches.

For the sake of diminishing the evaporation and of measuring small quantities of rain with greater precision, the diameter of the cylinder is sometimes reduced to two inches, and the collected water is, by means of a small pipe, inserted in the bottom of the cylinder, and furnished with a cock, made to pass into a glass tube whose interior diameter is half an inch. In this case, the diameter of the upper extremity of the funnel being the same as before, the area of the surface which receives the rain from the atmosphere will be to the area of a horizontal section of the glass tube as 576 to 1. Consequently a shower of rain whose depth on the ground might be one-hundredth part of an inch would be indicated by 5·76 inches in the tube.

The funnel of the cylinder may be of tin or copper, and, however the instrument be constructed, it is evident that it should be placed in a vertical position in some place where no object may interfere with the free descent of the rain into the funnel. It is usual to observe the quantity of water in the vessel every morning, if rain has fallen during the preceding twenty-four hours; but, as some evaporation will take place, it would be advantageous to make the observations more frequently.

The sum of all the depths observed during any period of time, as a day, month, or year, will give the whole quantity of rain which has fallen in that time at the place. It is supposed that the rain falls uniformly over the tract of ground lying within the limits of the shower, and consequently that the quantity which passes through the circular area at the upper surface of the cone is equal to that which falls upon an equal area of ground anywhere within those limits.

A rain-gauge can never serve further than to give an approximation to the quantity of rain which may have fallen, since some of the water will always adhere to the sides of the vessel, but the following method of ascertaining the allowance to be made for the quantity thus lost has been recommended:—Let a sponge be made damp, yet so that no water can be squeezed from it, and with this collect all the water which adheres to the funnel and cylinder after as much as possible has been drawn off; then, if the sponge be squeezed and the water from it be received in a vessel which admits of measuring its quantity, a near estimate may be made of the depth due to it; and this being added to the depth given by the instrument would probably show very correctly the required depth of rain.

RAINBOW: a circular arch of variously coloured light which is visible in the heavens when the sun or moon is shining, and when, at the same time, a shower of rain is falling on the opposite side of the spectator. When the rain is abundant, a second bow is commonly seen on the exterior, and concentric with the first; their common centre being in a line drawn from the luminary through the eye of the spectator and produced towards the opposite part of the heavens. Both bows consist of concentric bands of the different prismatic colours arranged as they appear in the solar spectrum, but the order in which they are disposed in the first bow is inverted in the second. The lower edge of the interior bow is violet and the upper edge is red; on the contrary, the lower edge of the exterior bow is red and the upper edge is violet.

The rainbow is a phenomenon which appears at all times to have been understood to depend upon the light of the sun or moon and the drops of falling rain, but the first complete explanation of the circumstances connected with it is due to Newton (*Optics*, lib. i., p. 2, prop. 9). In the beginning of the sixteenth century no better notion was entertained of the cause of the phenomenon than that the interior bow was a distorted reflection of the sun's image from the surface of a cloud, and that the exterior bow was a reflected image of the first. But the reflexion of light is not capable of producing different colours, and it is said that Fleischer of Breslau (1571) was the first who entertained the idea that the particles of light from the sun entered into the drops of rain. His opinion was that a ray of light suffered one refraction on entering and another on leaving a drop; and that it entered the eye of the spectator after reflection from the surface of a second drop. It appears that Kepler, in a letter to Harriot (1606), suggested that the particles of light, in a ray which is a tangent to some part of the surface of a drop of rain, might enter the drop by refraction, and that this ray, being subsequently reflected at the interior surface of the latter, might enter the eye of the spectator after being again refracted on leaving the drop. The hypothesis is worthy of Kepler's sagacity, and, as far as it goes, it differs from the fact only in the manner in which the incident ray is supposed to fall on the drop. Newton ascribes the first idea of the true explanation to Antonio de Dominis, bishop of Spalatro, whose work, 'De Radiis visûs,' was published in 1611, but is said to have been composed in 1590; the work however appears to have been so obscurely written and to betray so much ignorance of the laws of optics, that it is doubtful whether or not the author had any more than a vague conception of the cause of the colours. (See Montucla, *Histoire des Math.*, tom. ii.)

Descartes is certainly the first who has distinctly explained the causes by which the two bows are produced, and he states (*Meteora*, cap. viii.) that he detected those causes on observing the phenomena presented by a glass globe filled with water, which he placed in various positions with respect to the sun. He shows that the interior or primary bow is produced by rays from the sun falling upon the drops of rain near their upper surfaces, where, being refracted, they pass to the side of the drop which is farthest from the sun and spectator; from thence they are reflected towards the lower surface, and, on quitting the drop, they suffer a second refraction. He shows also that the exterior or secondary bow is produced by rays from the sun falling upon the drops of rain near their lower surfaces, where, being refracted,' they pass, as before, to the farther side of the drop; from tnence they are reflected towards the upper surface, and there they suffer a second reflection. After this they pass to the side of the drop which is nearest to the sun, and from thence they emerge after a second refraction. Now it is not sufficient that the pencils of light which are incident on the drops of rain should be so refracted and reflected; it is moreover necessary that each pencil on emerging from the drop should consist of parallel rays of light, that, when it enters the eye of the spectator, it may produce in the mind the perception of brightness; and Descartes determined by computation the positions of the incident and emergent rays so that this effect may be produced.

Thus, let SI (*fig.* 1) be a very slender pencil of rays of some one colour incident on a spherical drop of water at the

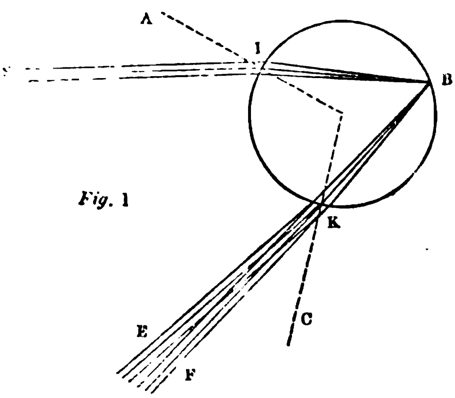

Fig. 1

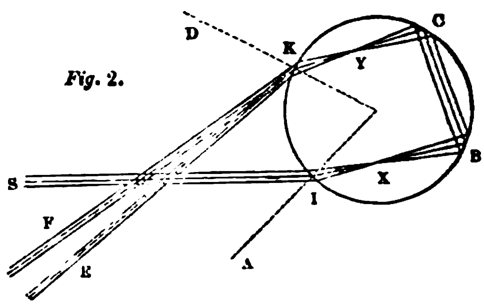
angle AIS, and let this angle be such that the rays in the pencil may, by the laws of refraction in water, converge at B; then, though many rays will pass through the drop at that point and be dispersed, yet many will be reflected from thence as from a radiant point, and will emerge at K in parallel directions, as they entered at I, so that if KE be the direction of the emergent pencil, the angle CKE will be equal to AIS: the angle made by the lines SI and EK produced was found by Descartes to be about 42 degrees. If the angle AIS were varied, the rays of the pencil would leave the drop in a divergent state, and then the impression which they would make on the eye might be too feeble to produce the sensation of brightness. Again, let SI (*fig.* 2) be a very slender pencil of rays of some one colour incident on a spherical drop of water at the angle AIS, and let this angle be such that, by the laws of refraction in water, the rays

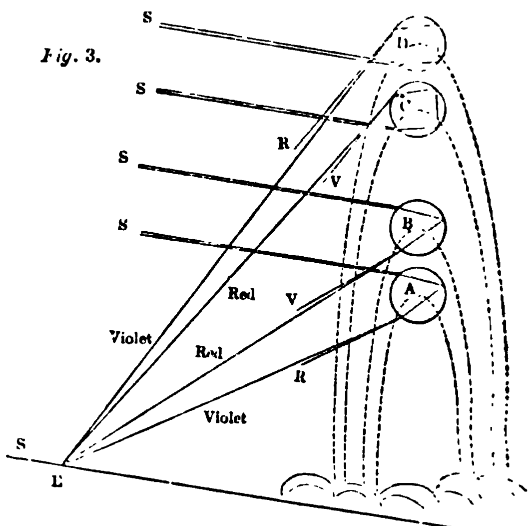
Fig. 2.



after crossing at X and being reflected from B may pass from B to C in parallel directions; then, after a second reflection, crossing at Y and being refracted at K, they will emerge in parallel directions as they entered at I, so that if KE be the direction of the emergent pencil, the angle DKE will be equal to AIS: the angle made by the lines SI and EK was found by Descartes to be about 52 degrees. If the angle AIS were varied, the rays of the pencil would leave the drop in a divergent state.

Now let A, B, C, D (*fig.* 3) be four globules of rain in a

Fig. 3.



cloud covering a considerable part of the heavens on one side of the horizon. Let E be the eye of the spectator, and, on account of the remoteness of the sun, let the rays of light which proceed from his disk be considered as parallel to one another. Let SE be a line drawn from the sun through the eye of the spectator, and let it be produced towards O; also let SA, SB, &c. be very slender pencils of parallel rays (supposed at present to be of one colour) falling upon the globules of water. Let the refraction and reflection of these pencils in A and B be similar to those which are shown in *fig.* 1; and the refraction and reflection in C and D be similar to those in *fig.* 2: also from the points of emergence suppose lines to be drawn to E. It is evident, on account of the parallelism of the lines SO, SA, &c., that if the angle AEO or BEO were nearly equal to 42°, and if the angles CEO or DEO were nearly equal to 52°, the eye would be affected by the sensation of brightness as explained above; therefore if the lines AE, BE, &c. were to revolve conically about EO as an axis, all the globules of rain upon the conical surfaces so described would send pencils of parallel rays to the eye, and two concentric arches of bright light would be seen in the heavens. This hypothesis accounts satisfactorily for the existence of two concentric bows of bright light, but it affords no indication of the bands of colours of which they consist. Descartes however very sagaciously refers their cause to the decomposition of light on entering and quitting the drops of rain; observing that the convex surfaces of the latter must produce effects similar to those which take place when light is made to pass through the plane faces of a triangular prism of water.

But when Newton had discovered the different degrees of refrangibility in the different coloured rays which compose a pencil of white or compounded light, he was able to assign immediately the cause of the coloured bands in the rainbow, the order of their position, and the breadth which they must occupy. Thus, if the incident pencil SI (*figs.* 1 and 2) had consisted only of violet-coloured light (for example), the angle AIS must have had that particular value which alone would allow the rays of the emergent pencil to be parallel to one another; but if the incident pencil were supposed to consist of light of another colour, as red, it should have fallen nearer to the centre of the drop, in order that the angle AIS might have the particular value which would allow the rays of the emergent pencil to be parallel to one another. Since the red rays suffer less refraction than the violet rays, if KF be the direction in which the latter emerge from a drop, KF in both figures may represent the direction in which the former would emerge; and if the eye be situated so as to receive the pencil KE, it would have the impression of a violet colour; while, if situated so as to receive the pencil KF, it would have that of a red colour. We have mentioned, for simplicity, only the violet and red rays, which form the two extremes of the coloured spectrum; but it is easy to conceive that a like explanation might be given for rays of the intermediate colours. And since the pencils of all the different colours diverge from one another on quitting a rain-drop, it is evident that the spectator whose eye receives one of the pencils will be affected by the colour of that pencil only, the other pencils passing either above or below his eye.

Newton has determined by computation that when the angle AEO (*fig.* 3) = 40° 17', the violet rays alone, after two refractions and one reflection, will enter the eye of the spectator at E, the other rays falling below; and when ∠ BEO = 42° 2', the red rays alone will enter the eye, the violet rays passing above. Again, when ∠ CEO = 50° 57', the red rays only will enter the eye, after two refractions and two reflections, the violet rays falling below; and when ∠ DEO = 54° 7', the violet rays alone will enter, the red passing above. If the interval between the drops A and B, and also between the drops C and D, were occupied by other drops, it may readily be imagined that the pencils of parallel rays which come from them to the eye would be of all the prismatic colours between the red and violet, and that thus there would appear in the heavens two narrow spectra: the length of that between A and B would be 1° 45', and of that between C and D would be 3° 10'. Therefore, if all the lines drawn to E from the drops in the two spectra were to revolve conically about EO as an axis, the drops on these lines would be in situations to send to the eye rays of their own proper colours, and thus there would exist the appearance in the heavens of two concentric bands of variously coloured light.

But it has been here supposed that the pencils SA, SB, &c. come from the centre only of the sun's disk, whereas each point of the disk produces two bows similar to those which have been described; therefore the lower extremity of the interior bow will be a violet band whose breadth is equal to half the diameter of the sun (suppose 15'), and which is situated immediately below the violet line formed by the centre of the disk; and in like manner the upper extremity of the interior bow will be a red band whose breadth is also = 15', and which is situated immediately above the red line formed by the centre of the disk: consequently the whole breadth of the interior bow is about = 2° 15'. Similarly 30' (the measure of the sun's diameter) must be added to the breadth of the outer bow, as before determined, which thus becomes about = 3° 40'. In both bows, the colours between the violet and red are less distinct than those two colours, because of the interference of the coloured light from all parts of the disk.

On account of the two reflections which take place in the interior of the drops which give rise to the outer bow, while there is but one reflection in those which produce the inner bow, there must be a greater quantity of light lost by transmission through the drops in the former case than in the latter; and hence the outer bow is always fainter than the other. The interval between the primary and secondary bow has occasionally been observed to be occupied by an arch of coloured light; but this, which is not always concentric with the others, has been ascribed to some reflection of one of those bows.

A rainbow can never be greater than a semicircle, if the spectator be not on elevated ground; for if it were, the centre of the bow would be above the horizon, and the sun, which is in a line drawn through that centre and the eye, would then be below the horizon; but, in this case, the sun could not shine on the drops of rain, and consequently there would be no bow. When the rain-cloud is of small extent, there is seen only that portion of the bow which the cloud can form; yet the bow is sometimes seen against the blue sky, when there exist in the air vapours which are not dense enough to be visible in the form of a cloud; and a portion of a bow has occasionally been seen in an inverted position on the ground by the refraction of the light in drops of rain adhering to the grass or the leaves of trees. It may be added that a coloured bow similar to that which is produced by rain may be observed in the spray from a fountain when the jet of water is agitated by the wind, and also in the mists which at times lie upon low grounds.

The lunar rainbows appear in general white; and when they are coloured, they differ from those produced by the sun only in the colours being much more faint.

The circle of light which is occasionally seen surrounding the sun or moon at some distance from the disk of the luminary, is called a *halo* or a *corona*, and is caused by the refractions of light in particles of ice which float in the air. This phenomenon having some resemblance to that which has been just described, a brief explanation of it may be with propriety introduced in this place.

The cause of the halo was first investigated by Descartes, who observes (*Meteora*, cap. ix.) that this phenomenon differs from the rainbow, inasmuch as the latter is seen only while rain is falling, whereas halos are never seen at such times; and he ascribes their formation to refractions of light in star-shaped crystals of ice, which he remarks are thicker in the middle than at the edges, and are therefore proper to produce refractions.

Sir Isaac Newton also ascribes the halo to refraction in floating hail or snow; but it appears that Mariotte (in 1686) was the first who considered it to be produced by refraction in the small equilateral prisms of ice which abound in the air in a separate state before they unite together and form the flakes which descend during severe frosts; and Dr. Young, without being aware of Mariotte's hypothesis, entertained and developed the same idea.

According to this philosopher, there may be in the air an immense number of prismatic particles whose transverse sections are equilateral triangles, the planes of the sections deviating but little from one passing through the sun or moon and the spectator. Now, by the laws of refraction in water, when a pencil consisting of parallel rays of light, as SI (*fig.* 4), is incident on a face of such prisms, and makes

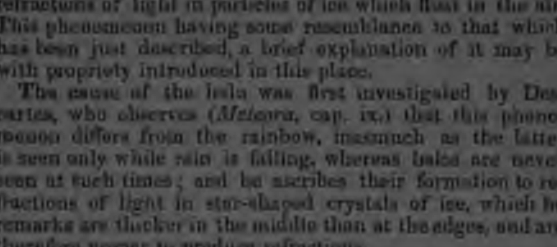


Fig. 4.

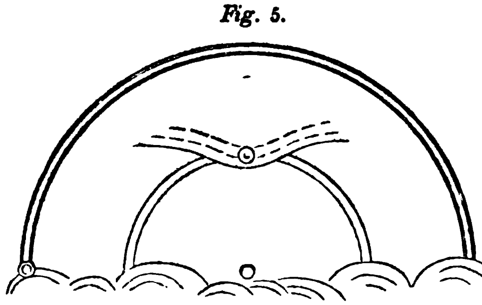
the angle of incidence SIP equal to about 41° 30', the axis KE of the emergent pencil will make an equal angle EKQ on the other face, and the angle of deviation SAF, or the angle between the incident and emergent ray will be 23° 40'. Therefore if the line FE produced to the spectator's eye were to revolve conically about a line joining the sun and spectator as an axis (which line, since the sun is very remote, may be considered as parallel to SA), all the prisms similarly situated on such conical surface would transmit to the eye pencils of parallel rays, if the light were of one colour, and thus there would be produced the perception of a bright circle in the heavens, having the sun for its centre; its radius subtending at the eye an angle of about 23° 40'. The angle SAF varies very slowly, the variation amounting only to about 3°, when the angle SIP varies as much as 30°: consequently there may be innumerable prisms in the air in such positions that the angle SIP, for pencils incident upon them, does not vary more than 15° on either side of that which has been above supposed; and these will transmit to the eye light in such abundance as to produce the appearance of an annulus about 2° broad. This is the appearance of the common halo. Dr. Young supposes further, that when there is a very great number of particles of ice so formed, the rays, after being refracted through one prism, may fall on another and there suffer a like refraction. This would produce the appearance of a second circle concentric with the former, and at twice its distance from the sun; thus there might be produced at one time two haloes, of which the distance of the exterior from the sun would be above 47 degrees.

The parhelia which sometimes appear above or below the true sun, are supposed to be produced by the refractions of light in equilateral prisms of ice, when such prisms happen to be very short, so as to have the form of thin triangular plates, and when the flat sides are in or near a vertical plane passing through the sun and spectator. A great number of such prisms would, by refracting the light as above shown, give rise in the halo to the appearance of a bright spot resembling the true sun, and in a vertical line passing through it; and, if the prisms in such positions have a certain length, the image of the sun would be distorted, and might assume the appearance of being winged. The horizontal parhelia are accounted for in a similar manner. Sometimes false suns (*anthelia*) appear on the side of the heavens which is opposite the true sun; and these are supposed to be produced by two refractions and two internal reflections in such prisms of ice. In this case the images ought to be 60° beyond the halo; that is, they ought to be about 83° from the true image of the sun.

Subjoined is a sketch of the double halo with parhelia, which was observed by Sir Henry Englefield at Richmond in 1802. (Young's *Nat. Phil.*; and *Journal of the Royal Institution*, vol. ii.)

Fig. 5.



RAISIN, or RAISEN, MARKET. [LINCOLNSHIRE.]

RAISINS. The dried fruits of several varieties of the vine are called raisins, a term derived from the French, raisin in that language being a general name for grapes, the dried fruit being distinguished as *Raisins secs ou passés*.

Raisins are named after the countries where they are produced, or the places whence they are imported; as Malaga, Valencia, and Smyrna. The peculiar small and generally seedless grapes, formerly called Corinths, are now better known as the dried or Zante currants of the shops. Other denominations by which different kinds of raisins are distinguished, arise from the variety of grape employed, or from the mode of preparation; as muscatels, blooms, sultanas, raisins of the sun, and lexias.

The most simple, and, when circumstances are favourable, the best mode of preparation is to dry the grapes, after being cut when fully ripe, by exposure to the heat of the sun on a floor of hard earth or of stone. Another method is to cut the stalk half-way through when the grapes are nearly ripe, and leave them suspended till the watery part is evaporated; the flow of sap is in a great measure prevented from entering the fruit, in consequence of the incision, and whilst evaporation continues to go on undiminished, desiccation must take place.

Some sorts are prepared by dipping the grapes in a ley, and afterwards drying them in the sun. This ley is formed of water, wood-ashes, and a small portion of oil of olives. The ashes of vine branches and tendrils are preferred. In Valencia, in addition to the ashes of rosemary and vine branches, a little slacked lime is used. Raisins so prepared are called lexias; whilst those prepared entirely by sun-heat are denominated raisins of the sun.

A fourth method, only used for raisins of inferior quality, is to dry the grapes in an oven.

The currant-grapes are gathered in the end of August and beginning of September. Rains often spoil the crop when they occur at the time of gathering or drying. The fruit, when sufficiently dry, is separated from the stalks by small rakes, and afterwards stored in magazines, '*seraglie*,' constructed somewhat like a lime-kiln, having an opening at top, where the fruit is put in, and a door at bottom, opened only at the time of sale. The fruit is rendered so compact by its own weight, that considerable force is requisite to break it up for the purpose of being packed in the large casks in which it is exported.

The Malaga raisins are esteemed the finest; and the muscatels from thence exceed all others in price by at least one-third. The black Smyrna raisins are those of least value.

Of all the known varieties of grapes, the white muscat of Alexandria is that which furnishes raisins of the finest description. The berries are large, oval, white, rather firm-fleshed, with a rich muscat flavour, superior in this respect to all others that have hitherto been fruited in this country. From the synonyms which it has obtained, its extensive cultivation and use as a raisin grape may be inferred; for example, it is called the muscat of Jerusalem, Malaga, Passé-Musquée, Passé-Longue Musquée, Muscat d'Espagne, &c. There is also a black muscat of Alexandria, and a red muscatel, both of which have a firmness of pulp which renders them fit for drying; for grapes, however rich they may be, and excellent in a fresh state, yet if they do not possess a certain degree of firmness, are unfit for drying, inasmuch as their substance would be too much dissipated in the process.

The variety of grape-vine that bears the small and generally seedless bunches of grapes, which, when dried, become the *Corinths* or *Zante currants* of the shops, belongs to *vitis vinifera*, and is not a distinct species, as it has been by some supposed. This has been proved by plants sent direct from Zante, and which have been fruited in the garden of the Horticultural Society. In a good season it is capable of being ripened against a south wall. The berries have the same size and character as those imported, being small and seedless, except occasionally one that acquires a somewhat larger size and contains a seed; such are even found amongst imported fruit. The variety is figured in the *Hort. Soc. Transactions* (2nd series), vol. i., p. 246. According to M. Beaujour, the first grapes of this variety that appeared in the great marts of Europe were brought at the beginning of the seventeenth century from the Gulf of Corinth, and hence were called *Corinthian* raisins. Latterly however the cultivation has become chiefly confined to the western territories of the Morea and the Ionian Islands, particularly those of Zante, Cephalonia, and Ithaca. The fertile island of Zante is the place where this variety of grape is produced in greatest abundance.

The chief employment of raisins in medicine is to flavour unpleasant mixtures, or for their demulcent properties. In the former point of view they are unimportant; in the latter, of considerable utility. Fresh grapes are cooling, aperient, moderately nutritive, and demulcent. Their use in the south of France is thought to contribute greatly to the amelioration which consumptive persons experience there, and in some instances their effect is so striking as to have given rise to the term *cure de raisins*. The dried fruit is less acid, but more nourishing, and more demulcent. It possesses all the soothing qualities of jujube, and is much cheaper. It may be easily made into a conserve by removing the seeds and beating the pulp into a thick mass. For persons with irritable throats and liable to winter coughs, a portion of this put into the mouth before going into the open air is an excellent protective measure, and often prevents cough, which, when once excited, it is difficult to allay. An excellent demulcent drink is made from a compound of barley and raisins. Currants contain more acid than common raisins, and should be preferred where an aperient action is desired.

An oil exists in the seeds of the grape, in the proportion of 12 pounds of oil to 100 pounds of seeds. Though it is not obtained without difficulty, it is extracted in Italy in large quantity. When heat is used, it has a harsh taste, and is mostly used for burning; but when cold-drawn, it may be used for food.

Tannin of the purest kind may be obtained from the seeds of the grape.

Nearly all the raisins imported into this country are from Spain and Turkey. Of the total quantity imported, 99 per cent. is from these countries, namely, 64 per cent. from Spain, and 35 per cent. from Turkey. A small supply is received from Portugal, Italy, and the Cape of Good Hope.

Malaga and Valencia are the two great Spanish ports of shipment. At the commencement of the present century, Laborde estimated the exports of Malaga at 240,572 cwts., valued at 695,000*l*., and those of Valencia at 96,500 cwts., valued at 11,800*l*. In 1829 however M. Moreau de Jonnès (*Statistique de l'Espagne*) estimated the total value of fruits exported from Spain at only 200,000*l*. In 1834 the exports of raisins from Malaga consisted of 774,056 boxes and 152,000 barrels, one-half of which were shipped for the United States, and one-sixth for England. Nearly the whole of the supply from Turkey is shipped at Chesmé and Vourla, small ports near Smyrna, the only raisins shipped at Smyrna being the small fine species called sultanas. Chesmé owes its prosperity entirely to this trade; and the Franks go down there in the month of October merely to ship the fruit which is produced in great abundance in the vicinity. Mr. Macfarlane states (*Constantinople in 1829*) that fourteen English vessels, three Austrian, and one American took fruit (many of them whole cargoes) during his stay in the town.

In August, 1834, the import duty on raisins was reduced to 15*s*. per cwt. on foreign, and 7*s*. 6*d*. if from British possessions. The duty had previously been:—from British possessions 10*s*., foreign sun 42*s*. 6*d*., other sorts 22*s*. (reduced in 1829 to 20*s*.). In the five years from 1829 to 1833 the old duty produced annually 151,749*l*.; and in the five years following the reduction from 1835 to 1839, the annual average duty amounted to 120,870*l*. The average annual consumption in the United Kingdom, in each of the following periods of five years, was as follows:—1820-4, 138,287 cwt.; 1825-9, 142,130 cwt.; 1830-4, 136,559 cwt.; 1835-9, 160,740 cwt. The consumption of 1839 exceeded any previous year, being 173,383 cwt. Since the reduction of the duty on foreign wines, the use of raisins in this country for making sweet wines has been greatly diminished, and thus the beneficial effect of lowering the duty on raisins is not so apparent as it would otherwise have been.

RAJA is a Sanscrit word, signifying king or ruler, and is the same word as the Latin *rex, reg-is*. In the antient writings of the Hindus the word is applied to all the different kings or princes of Hindustan, and the title is still given to native princes.

RAJAMUNDRY, the name of a district and town of Hindustan, in the presidency of Madras and province of the Northern Circars. [CIRCARS, NORTHERN.]

RAJASTHAN. [RAJPOOTANA.]

RAJMAHAL, a town of Hindustan, in the presidency and province of Bengal, on the west bank of the Ganges, in 25° 0′ N. lat. and 87° 50′ E. long. Though formerly a large city, and at one time the capital of the province of Bengal, it now consists of little more than a long street of mud huts, some tombs and dilapidated mosques, and the ruins of a vast palace, which was built by the Sultan Sujah, brother of the emperor Aurungzebe, and completed in 1630. In the following year however a fire destroyed the greater part of the town and a considerable part of the palace; and not long afterwards a branch of the Ganges changed its course, and carried away nearly all the houses which remained. The Mogul governor of Bengal was then obliged to transfer his residence to Dacca, and Rajmahal has continued in a state of decay ever since. Its population however is said to be still not much less than 30,000.

RAJMAHAL HILLS, a group of mountains which derive their name from the town of Rajmahal, near which the southern part of them commences: they extend about 60 miles northward along the west bank of the Ganges. They form a detached mass, resemble the greater part of the Welsh mountains both in height and general appearance, and occupy an area perhaps equal to Merionethshire and Caernarvonshire. They are bounded on all sides by a level country, and rise from the flat surface of Bengal as if out of the sea. They are well wooded, and there is much thick jungle, so that they abound in wild animals of all kinds, from the jackal to the tiger, and from the deer to the elephant and rhinoceros.

The Rajmahal Hills, and indeed all the hilly country between Rajmahal and Burdwan, are inhabited by the *Puharrees* (or mountaineers), who appear to be an aboriginal race, differing from the inhabitants of the plain in features, language, manners, and religion. They are easily distinguishable from the Hindus by their long narrow eyes, brownish faces, and flattish turned-up noses; in stature they are rather short, but strong and active. They live chiefly by the chase, in which they use bows and arrows, few of them having fire-arms, and they shoot the larger animals with poisoned arrows. In addition to hides and game, they dispose of wax and honey, in which their hills abound, and they cultivate millet in considerable quantity.

Their language differs very remarkably, both from the Hindostanee and the Bengalee, but is said to bear a striking resemblance to that of the Bheels and the Goands, so that these tribes are apparently different branches of the same great family, which extends over all the mountainous centre of India. [HINDOSTAN, p. 231.] At some remote period they have probably been driven to those mountain-wilds by the tribes professing the Brahminical faith.

The villages of the Puharrees are very small and wretched, but the inhabitants pay no taxes, and live under their own chiefs under British protection. The men, being chiefly occupied in hunting, dislike work, but the women are industrious in cultivating the little patches of garden round their villages. Each village has a chief, and a number of villages compose a district, over which also there is a chief. Inferior crimes are tried by a jury of five old men in every village, but capital crimes are tried in the presence of the European judge by an assembly of village chiefs presided over by a district chief. Polygamy is not forbidden, but is rare.

The Puharrees have no castes; they care nothing for the Hindu deities, and they have no idols or images of any kind. A black stone, found in the hills, is consecrated by some ceremonies, and used as an altar. Buffaloes, hogs, fruits, fowls, grain, and spirits, are on certain occasions offered up to the gods, and afterwards feasted on. Prayer to 'Bedo Gossee,' which in their language means the supreme God, is strictly enjoined and practised morning and evening. They have several inferior deities, and also some evil ones. They believe that the souls of the good are sent back to earth in the bodies of great men, and those of the wicked in the form of brutes and even trees.

Till within the last sixty years a deadly feud had existed between the Puharrees and the inhabitants of the neighbouring lowlands, and as the former were continually making forays, the Mohammedan zemindars shot them like mad dogs whenever they came within reach. But Mr. Cleveland, having been appointed judge of Boglipoor, rigorously forbade and promptly punished all violence from the zemindars against the Puharrees; he got some of the latter to enter his service, and took pains to attach them to him, and to learn their language; and at last raised a corps of Sepoys from among them, which he stationed at Sicrigully. Judge Cleveland died in 1784, in the twenty-ninth year of his age, and a monument was raised to his memory near Boglipoor, at the joint expense of the Puharree chiefs and the lowland zemindars, and was endowed by them with some lands for keeping it in repair. The natives meet once a year, in considerable numbers, and have a handsome 'poojah,' or religious spectacle, in honour of Cleveland's memory. A school has since been re-established by Lord Hastings, for the Puharrees, at Boglipoor, which was originally set on foot by Cleveland, but was shamefully neglected by his successors in office.

(Heber's *Narrative of a Journey through the Upper Provinces of India*, London, 1828.)

RAJPOOTA'NA, an extensive territory of Hindustan, so called because the greater part of it belongs to the Rajpoot princes. It is, to a considerable extent, coincident with the antient province of *Ajmeer*. *Rajast'han*, or 'the abode or country of princes,' is another name for the same territory. Rajpootana is situated between 23° 45′ and 31° N. lat. and 70° 23′ and 77° 45′ E. long. It is bounded on the north by Lahore, on the north-west by Moultan, on the west by Sinde, on the south by Gujerat and Malwa, and on the east by Agra and Delhi; but the boundaries are very irregular, and not distinctly defined. Its greatest length, from south to north, is about 480 miles, and its greatest breadth, from east to west, about 400 miles. If estimated as a square, each side would probably be about 300 miles; so that its territory may be reckoned at 90,000 square miles, or about 6000 square miles more than the area of Great Britain.

Rajpootana is divided into eight principalities, besides the Batti country, or Hill States. The principalities are—Jypoor, Kotah, Boondee, Mewar (or Oodipoor), Marwar (or Joudpoor), Tonk, Jessulmer, and Bikaneer. The city of Ajmeer, with a small territory surrounding it, belongs to the British.

The great chain of the Aravulli mountains stretches, in a north-eastern direction, through the greater part of Rajpootana, from the hilly country which connects it with the Vindhya mountains almost to the confines of Delhi. [ARAVULLI.] Nearly the whole of the country west of the Aravulli is a sandy waste, extending northward to the Ghurra branch of the Indus, and rising towards the south in a succession of steppes. In this barren territory are comprised the principalities of Marwar, Jessulmir, and Bikanir. A few oases occur, the largest of which are those in which the towns of Joudpoor, Jessulmir, and Bikanir have been built. To the north-east is the country of the Batti, the Hill States, which is separated from Lahore by the Sutledj. It is mountainous to the east, and encroached on by the desert to the west, but that part which is watered by the Gagor is very fertile, and produces corn, rice, sugar, and tobacco. To the east of the Aravulli mountains, and running nearly parallel with them, are the Chitore mountains. [HINDUSTAN, p. 214.] The country between the two ranges, which is from 60 to 100 miles broad, comprises the principalities of Mewar, Boondee, Tonk, and Jypoor. Kotah is on the east side of the Chitore mountains, in a rocky district.

Rajpootana, west of the Aravulli mountains, is for the most part little better than a desert; vast tracts of it consist of nothing but fine sand, on which not a blade of grass grows, and which the winds form into hills, sometimes 80 or 90 feet high, which continually change their form and position, so as to render it dangerous to pass across those parts of the country where they occur. In some places the sand is more consolidated, and mixed with stones, and produces stunted bushes and coarse grass, which affords a scanty supply of pasturage to a few herds of camels and flocks of sheep in the season when the periodical rains occur, which however are of short duration and not abundant. A village is found here and there, consisting of huts made of straw, and surmounted by a conical roof. A few fields surround the huts, and these are enclosed by a hedge of stunted thorns. Nothing can be more wretched than the appearance of these villages and their miserable inhabitants. The aspect of the country somewhat improves as it rises towards the Aravulli mountains on the south-east: the oases become more frequent, and those large ones in which the great towns of Jessulmir, Bikanir, Nagore, and Joudpoor are situated, are tolerably fertile. The whole of Marwar indeed has a better soil and is in a better state of cultivation than the other principalities on the west of the Aravulli mountains, and as good as most parts of those on the east. There are numerous wells for irrigating the land, but as they are very deep, agriculture is expensive. Still the villages are in a good state; the corn looks well; the cotton is as fine as any in India; and the oxen and sheep are large and highly prized. There are no fruit-trees, but the water-melon is in great abundance. The principality of which Joudpoor is the capital is described in the article MARWAR.

Rajpootana, east of the Aravulli range, though its soil is of a similar sandy character to that on the west, is much more fertile and generally better cultivated. The periodical rains are more abundant and continue longer, and wells for the purpose of irrigating the land in the dry season are very numerous. These wells are of two kinds, common draw-wells and 'boolees.' The common draw-wells are often very deep, sometimes upwards of 200 feet. The manner of sinking them is curious, and perhaps the only one which would be practicable in a deep loose sand. A circular hollow tower of masonry, of a suitable diameter, and fifteen or twenty feet high, is constructed, and is left standing for a year or more, till it is well consolidated and set. The sinking of the well is then commenced, and the tower, being undermined, sinks gradually and steadily down, forming the casing of the well. When the top of the tower has reached the surface of the ground, more masonry is added, and thus the sinking proceeds till water is reached. The boolees are square pits, lined with hewn stone, fifteen or twenty feet across, and sixty or seventy feet deep. A flight of broad stone steps at one side descends to the water's edge. On the opposite side, at the top, is a pulley, as in the common wells, to draw up the water by oxen. The steps are used by persons who desire to wash themselves, or who have not rope enough to reach the water from the surface. Many of these boolees are very beautiful, with noble staircases, and with a kind of portico and pillars, richly wrought, as an approach to them. The practice of having steps down to the edge of the water arises from the religious observances of both Mohammedans and Hindus, which make washing an accompaniment of prayer. For irrigating the land the water is drawn up in a large leathern bucket, by oxen, over a rude pulley, and poured by the labourer into the 'gools,' or small channels, by which it is conducted to the fields. For ablution and other purposes an earthen jar is let down by a string from some of the galleries which are constructed on the flight of steps; those who have not this convenience are obliged to go down to the bottom with a skin, and bring the water up on their heads or backs.

The principality of Jypoor, with its capital, is described under JYENAGHUR. The small territories of Boondee and Tonk may be considered as included under the same head. The principality of Kotah, though small, is somewhat larger than the two preceding. It escaped the ravages of the Pindarees through the bravery and talents of the regent Zalim Singh, who by the employment of very limited means made his little territory a sort of Eden amid the surrounding misery which those ferocious robbers occasioned, and his court became an asylum for the unfortunate from every neighbouring principality. The town of Kotah is seated on the Chumbul, a branch of the Jumna, in 25° 12′ N. lat. and 75° 47′ E. long.

Mewar, though mountainous, is tolerably fertile, and produces all kinds of grain, sugar, indigo, cotton, and opium, but not enough of the last to export any. Good pastures are rare, and the cattle are smaller than in the neighbouring districts. Mewar suffered to a dreadful extent from the Pindarees, and has since only partially recovered from the desolation which they occasioned. Oodipoor, the capital of Mewar, is in 24° 34′ N. lat. and 73° 45′ E. long. It is seated in a mountainous district, and is a place of great strength, which can only be approached by three narrow defiles. Chitore, the former capital, having been taken by the Mohammedans, Oodipoor became the residence of the raja, or ranah, as he is called. This Hindu family is one of the oldest and purest in India, and its members have steadily resisted any attempts at intermixture either with Mohammedans or Hindus, always intermarrying with one another. The town of Chitore is situated in a rocky plain, in 24° 53′ N. lat. and 74° 45′ E. long., on the banks of the Bunnass, over which are the ruins of a long, lofty, and handsome stone bridge of eight Gothic arches, and one semicircular one in the centre. Chitore is a tolerably large town, with many pagodas and a meanly built bazaar. There is a beautiful minaret, dedicated to Siva. It is a square tower upwards of one hundred feet high, consisting of nine stories of white marble elaborately and tastefully sculptured, and surmounted by a cupola, the two highest stories projecting like balconies, so that it is smaller at the bottom than the top. A fortress of great strength and considerable extent, including the former palace of the ranah of Oodipoor, is situated on the top of a high rock close to the town.

Ajmeer, in 26° 28′ N. lat. and 74° 42′ E. long., is a moderate-sized town on the slope of a high hill. The houses are well built, and are mostly whitewashed. On the top of the hill is a remarkable fortress called Taraghur, which is a place of great strength, and is in most parts inaccessible. Ajmeer is resorted to by great crowds of Mohammedan pilgrims, who come here to visit the tomb of Shekh Kajah Mowud Deen, a saint whose miracles are celebrated all over India. Just above the town of Ajmeer is a large lake, which was formed by the emperors of Delhi by damming up the outlet of an extensive valley, into which a number of rills were conducted. The lake is four miles in circumference in dry weather, and six during the rains. It affords the means of irrigation to a large district on its banks, supplies abundance of excellent water to the inhabitants of Ajmeer, and is full of fish. In 1818 the city of Ajmeer, with the surrounding district, was ceded to the British by Dowlet Rao Sindh, in exchange for a part of the territory of Malwa.

The other principal towns of Rajpootana which have not been noticed, are the following:—Bikanir, in 27° 58′ N. lat. and 73° 20′ E. long., a large town surrounded by a wall and ditch. The raja resides in a fort not far from the town, where there is an excellent spring of fresh water. Boondee, the capital of the principality of Boondee, is a small town on the side of a range of hills, on the summit of which is the raja's palace, a large stone edifice strongly fortified. Jessulmur. [HINDUSTAN, p. 221.] Tonk, on the Bunnass, in 26° 12′ N. lat. and 75° 47′ E. long. Kishengurh, in 74° 57′ N. lat. and 26° 38′ E. long., situated on a chain of granite hills, surrounded by walls of solid masonry, and with its castle on the mountain top. The raja's palace is a large but rudely-built fort on the banks of a fine pond. Wuerh is a large town surrounded by a high mud rampart well flanked by semicircular bastions, and with a wide but shallow ditch.)

The principal rivers of Rajpootana are—the Chumbul [HINDUSTAN, p. 215]; the Bunnass, an affluent of the Chumbul; and the Loony, or Salt River, which flows through Marwar, and disappears in the great salt marsh of the Runn.

The climate of Rajpootana is oppressively hot in summer, with parching winds. In winter it is colder than is pleasant in a country where fuel is everywhere scarce and extremely dear. The dried dung of camels or cows is almost universally used for fuel. Wood for burning or building is only grown in the north-east on the confines of Agra.

The vegetable productions of Rajpootana will be sufficiently known from the preceding descriptions. Of wild animals there are tigers, wolves, foxes, and wild hogs. East of the Aravulli mountains large herds of deer are occasionally met with, which are found to be extremely tame in a country where they are seldom used as food. There are considerable numbers of camels, oxen, and some buffaloes, large flocks of sheep, and an excellent breed of horses. The pea-fowl is regarded as a sacred bird, and is very abundant, as is also a beautiful green pigeon, and both are as tame as barn-door fowl. There are mines of iron and lead. Salt, cattle, camels, horses, and cheese are exported from Rajpootana by the ports of Gujerat. At Sambur, about forty miles west from Jypoor, is a large salt lake, which supplies the greater part of western and northern Hindustan with that useful article.

The inhabitants of Rajpootana are generally Hindus, but there is a considerable number of Mohammedans. Probably the whole population does not exceed 3,000,000, and consists principally of Rajpoots, Bheels, Jains, Jauts, and Mairs, besides the Mohammedans. The Rajpoots are Hindus. Till they came under the protection of the British they were little better than robbers, and were engaged in incessant warfare with each other: consequently the towns and many of the larger villages of Rajpootana are fortified, and generally placed in situations where they might be protected by a fortress on a rocky height. The Rajpoots, though more peaceable than they were, are not improved in other respects. They are described as idle, and addicted to intoxication, opium-eating, and other kinds of sensuality. The Bheels or Bhils [HINDUSTAN, p. 221] are a wild race, who dwell generally in the mountain-fastnesses, whither they appear to have been driven by the Rajpoots. They bear a strong resemblance to the Puharrees of Rajmahal, and by similar treatment might probably be similarly improved. [RAJMAHAL HILLS.] The Jauts are in considerable numbers in all parts of Rajpootana, and the whole of the Batti tract may be considered as belonging to them. The Mairs are described in the article ARAVULLI.

The Rajpoot states were never properly subjected by the Mohammedan emperors; for though they were compelled to pay a tribute and furnish a certain number of mercenary soldiers, they continued in a state of half independence, and their continual revolts occasioned their principal cities to be several times destroyed. After the death of Aurungzebe, in 1707, Rajpootana continued nominally subject to the emperor of Delhi till 1748, when its chiefs became independent. Since then the desolating attacks of the Mahrattas have compelled them to place themselves under the protection of Great Britain. The rajas of Rajpootana are independent sovereigns, but an English officer commands its forces, and a garrison has been established at Ajmeer sufficient for its protection against its enemies, and also to keep the Rajpoot chiefs themselves in subjection.

RALEIGH, SIR WALTER, born in the year 1552, in the parish of Budley, on the coast of Devonshire, was the second son of Walter Raleigh and his third wife Catherine, daughter of Sir Philip Champernon and widow of Otho Gilbert, Esq. of Compton, Devon. Sir Humphry Gilbert, whose name is connected with the attempts to discover a north-west passage, was Sir Walter Raleigh's half-brother. In the retired neighbourhood of Budley, Raleigh received the rudiments of his education. He was entered a commoner of Oriel College, Oxford, in or about the year 1568, where, to use the words of Anthony Wood, 'he was worthily esteemed a proficient in oratory and philosophy.' In 1569 Raleigh accompanied his relative Henry Champernon with a volunteer corps to France in aid of the Huguenots. He served in France five years, and subsequently in the Netherlands, as a volunteer under the Prince of Orange. In 1578 Sir Humphry Gilbert obtained a patent to colonise any parts of North America not settled by the allies of England. Raleigh and Gilbert attempted a joint expedition, from which Raleigh returned unsuccessful in 1579. In the next year we find him commanding a company of the royal troops in Ireland during the rebellion raised by the earl of Desmond; he was one of the officers to whom the charge of murdering the Spanish prisoners was committed by Lord Deputy Gray. Some difference arising between the lord deputy and Raleigh, the latter was called upon to defend himself before the council, which he did with so much ability and grace that he gained the queen's ear. The romantic incident which tradition gives as the origin of his favour with the queen is well known. Elizabeth's partiality for handsome men was notorious, and Raleigh's personal recommendations were great. In two or three years from the time he was introduced at court he was knighted, made captain of the guard, seneschal of the county of Cornwall, and lord warden of the stannaries, and he received a grant of 12,000 acres of the forfeited estates of the Earl of Desmond, and a lucrative patent for licensing the vendors of wine in England. In 1583 Sir Humphry Gilbert sailed on a second expedition to North America, towards which Raleigh, now too much engaged at court to accompany it himself, subscribed 2000*l*. This attempt also proved abortive, and Gilbert perished on his return in a storm in which his ship foundered. Raleigh, undismayed, obtained for himself in 1584 a patent investing him with power to appropriate, plant, and govern any territories that he might acquire in North America. In 1585 the first body of colonists landed, under the government of Mr. Lane, in Virginia, so called in honour of the virgin queen. Harriott, a celebrated mathematician of the day, went out to survey the colony; his survey and report, and the introduction of the tobacco-plant into England for the first time, were the only fruits of this attempt. [HARRIOTT.] The misconduct of the colonists brought the hostility of the Indians upon them; and they re-embarked within a year on board Sir Francis Drake's squadron, who visited the Chesapeake on his homeward voyage. A second body went out in 1587; but this expedition also failed; the governor returned home for fresh forces, which were very difficult to obtain, as he arrived in the height of the preparations for the Spanish invasion. Raleigh however dispatched two small vessels, which were plundered at sea, and forced to put back; and when at length assistance was sent out, the colonists had been murdered by the Indians. In 1589, finding that his resources were unequal to the forming of a colony, he made over his patent to a company of merchants. Raleigh has been charged with neglecting those wretched men who were left among the Indians; but it appears from Purchas, that previous to the year 1602, he had sent five several times, at his own charges, to find these people, who were left in Virginia in 1587 (iv., p. 1653). This is a sufficient answer to the charge; but it is somewhat difficult to comprehend, why these few adventurers, in number about one hundred, should not have left the country where they were unable to maintain themselves, if they had the opportunity.

In 1587 Raleigh had been appointed one of a council of war to put the forces of the realm in the best order to withstand any invasion, and had command of the forces in Cornwall, of which county he was lieutenant-general. In July, 1588, after the Armada had passed up the Channel, he joined the British fleet with a small squadron, and greatly distinguished himself in the several engagements which ended in the discomfiture of the Spaniards. As a reward for these services he received an augmentation to his patent of wines, and the right to levy tonnage and poundage on them. In 1589 he accompanied the Lisbon expedition under Drake and Norris, the object of which was to place Don Antonio on the throne of Portugal. [ANTONIO.] In 1591 he sailed on an expedition to intercept the plate fleet, which was unsuccessful; and during his absence, the queen having discovered that an intrigue existed between Raleigh and Elizabeth, daughter of Sir Nicholas Throckmorton, one of the maids of honour, he was, immediately on his return, thrown into the

Tower. Raleigh married Miss Throckmorton, and on being released after a short confinement, retired to his estate of Sherborne in Dorsetshire. It was during this retirement that he formed his scheme for the discovery and conquest of El Dorado, that fabulous land of gold and unbounded wealth in the interior of South America, in the existence of which he firmly believed. On the 5th of February, 1595, Raleigh sailed from Plymouth with five vessels, and arrived at Trinidad about the end of March. He surprised the newly founded town of S. Josef, and took prisoner the governor, Don Antonio Berrio, from whom he extracted information which enabled him to ascend the Orinoco about 60 leagues, when he was forced to return. He arrived in England towards the end of the summer, 1595. Raleigh published an account of this voyage, under the sounding title of 'The Discovery of the large, rich, and beautiful empire of Guiana,' a work which had not the merit of any methodical arrangement of the matter, though it contains numerous vigorous passages, such as characterise the style of Raleigh. That Raleigh, though not without a disposition to the marvellous, actually believed all that he wrote, is hardly an admissible supposition. His regard to truth was never so strong as to prevent him from embellishing facts real or supposed, when he thought he could thus gain his ends. His restoration to favour at court, which took place shortly after, prevented any further prosecution of his designs on Guiana during the reign of Elizabeth. In 1596 he was employed, with the rank of rear-admiral, at the taking of Cadiz, where he greatly distinguished himself, and was severely wounded in the leg. In 1597 he took Fayal. About this time he was restored to his post of captain of the guard, and appointed governor of Jersey. He now became deeply engaged in court intrigue, and combined with Cecil, who afterwards crushed him, to destroy the Earl of Essex. He strongly urged Cecil, in a letter which appears among his works, to put down the earl; but it is doubtful whether this letter was written before or after the condemnation of Essex, as it has no date. Raleigh turned his influence with the queen to good account, by procuring a remission of the sentence for such of Essex's adherents as could afford to purchase his good offices. One of these, Mr. Littleton, paid Raleigh 10,000*l.* A transaction so shameless has no other apology than that it was not condemned by the opinion of the age. Bribery and corruption were universal, and we cannot expect a man of Raleigh's character to have had a higher standard of morality than his contemporaries. In the house of commons, of which he had been elected a member some years before, he made himself conspicuous by advocating principles far before his age: he maintained that every man should be left at liberty to employ his capital and labour where and how he liked, and that all restrictions on the trade in corn should be removed.

After the death of Elizabeth, Raleigh's fortunes fell. His haughtiness and rapacity, with the share he had in the ruin of Essex, had made him universally disliked; and Cecil, his former friend and associate, had completely poisoned James's mind against him. The post of captain of the guard was speedily given to another, and his wine-patent was withdrawn. An opening soon offered for a more serious attack. James had not long been seated on the throne before two or three plots against him were discovered. Among these was one named the Spanish or Lord Cobham's treason. Lord Cobham being intimate with Raleigh, the idea of his participation instantly suggested itself. Raleigh being examined before the council, declared his utter ignorance of any plot, but admitted that he was aware of some intercourse having taken place between Cobham and the Count D'Aremberg, the Flemish ambassador, and he recommended that La Renzi, one of that nobleman's suite, should be examined. This being made known to Cobham, he flew into a violent rage, declared that in all his intrigues he had been instigated by Raleigh, and that the money to be paid by Spain was to be lodged in the island of Jersey, of which island Raleigh was governor. He shortly afterwards fully and solemnly retracted all that he had said against Sir Walter, who was nevertheless committed to the Tower on a charge of high-treason, in July, 1602. While there he made an attempt at suicide by stabbing himself. In September, 1603, Raleigh was tried at Winchester, and found guilty. Doubts have frequently been thrown on the whole of the facts connected with Raleigh's accusation. That his condemnation was procured by the power of his enemies, and that the verdict of the jury was not justified by the evidence, there can be no doubt; but the French ambassador, Beaumont, considered him morally guilty. It is certain that such a plot did exist for placing Lady Arabella Stuart on the throne, that the archduke knew of it, and that his minister Aremberg had corresponded with Cobham on the subject, and had promised a sum of money in support of it. It seems probable, indeed almost certain, that Raleigh was aware of Cobham's correspondence, although he might not be an actual participator in the plot. Some judicious writers are of opinion that he was even a principal mover in it. The best account of this celebrated trial is in Mr. Jardine's 'Criminal Trials' (*Library of Entertaining Knowledge*), to which we refer for some interesting remarks as to the supposed illegality of the procedings on Raleigh's trial, and on the state of the criminal law at that time.

Raleigh's conduct during his trial entirely changed the general feeling of dislike entertained towards him: an eye-witness observed, 'In half a day, the mind of all the company changed from the extremest hate to the greatest pity.' He was reprieved and sent to the Tower, where he was confined for thirteen years. His family suffered severely by his attainder: he had some years before conveyed his estate of Sherborne to his son, reserving his own life-interest, which was now forfeited, and a slight flaw being discovered in the deed of conveyance, Carr, the king's favourite, petitioned for and obtained the estate himself, reserving only 8000*l.* as a compensation for Raleigh's family. During his long imprisonment he turned to intellectual pursuits, and, with many minor pieces, executed his greatest work, 'The History of the World,' a project of such vast extent, that the bare idea of his undertaking it excites our admiration. As an author, Hume says, 'he is the best model of our antient style,' and Hallam observes that he is 'less pedantic than most of his contemporaries, seldom low, and never affected.' The first part of the 'History of the World,' which is all that Sir Walter Raleigh completed, is contained in five books, commencing with the creation, and ending with the second Macedonian war, about 180 years before Christ. The following extract gives a good specimen of the style, while it accounts for his not continuing the work: 'O eloquent, just, and mighty Death! whom none could advise thou hast persuaded: what none hath dared, thou hast done: and whom all the world hath flattered, thou only hast cast out of the world and despised: thou hast drawn together all the far-stretched greatness, all the pride, cruelty, and ambition of man, and covered it all over with these two narrow words, *Hic jacet!*'

'Lastly, whereas this book, by the title it hath calleth itself the "First part of the General History of the World," implying a second and third volume, which I also intended, and have hewn out; besides many other discouragements persuading my silence, it hath pleased God to take that glorious prince (Prince Henry) out of the world to whom they were directed, whose unspeakable and never enough lamented loss hath taught me to say, with Job, "Versa est in luctum cithara mea, et organum meum in vocem flentium."'

In 1615, Cecil being dead, and Somerset disgraced, Raleigh bribed the uncles of Buckingham, the new favourite, and induced Sir Ralph Winwood to recommend his project of opening a mine in Guiana. Upon this he was released conditionally. He equipped thirteen vessels for this expedition, which, from the magnitude of the undertaking and the celebrity of his name, attracted much attention, and Raleigh's ship was visited by all the foreign ambassadors. A writer in the 'Edinburgh Review' (No. cxliii., p. 82) gives an extract from a dispatch of Count Desmarests, the French minister, deeply implicating Raleigh's honour; it is to this effect: Raleigh 'resolved to abandon his country, to make the king of France the first offer of his services and acquisitions, if his enterprise, from which he confidently expected great results, should succeed.' The fleet reached the Coast of Guiana about the middle of November, 1617. Raleigh was so unwell that he could not ascend the Orinoco in person. Captain Keymis, the steady follower of Raleigh, led the exploring party, consisting of five companies of fifty soldiers each. A conflict took place with the Spaniards near St. Thomas, a small town recently built, in which the Spanish governor and Raleigh's eldest son Walter were slain: after which Keymis, having spent about twenty days in a fruitless search for the mine, and suffered considerable loss, returned to the fleet. Keymis, meeting with nothing but reproaches for his ill success, committed suicide. Raleigh sailed for Newfoundland to victual and refit; intend-ing afterwards possibly to return to Guiana, but certainly in the mean time to attack the Spanish plate fleet, if he could fall in with it. Before he reached Newfoundland the fleet separated, and on his arriving there, his own crew mutinied, and the majority declaring for a return to England, he was forced to accompany them. He arrived at Plymouth in July, 1618, and was shortly after arrested by Sir Lewis Stukely, Vice-Admiral of Devonshire. He was conveyed to London, and on his journey made some ineffectual attempts to escape, and at Salisbury he feigned sickness. James, strongly urged by the King of Spain to punish Raleigh for his attack on St. Thomas, and being anxious to gratify that monarch, laid the case before his council, when it was argued that Raleigh, being under an unpardoned sentence for treason, was civilly dead, and accordingly could not be tried again. James therefore resolved to carry into execution a sentence fifteen years old, which had been followed by an imprisonment of thirteen years. He was brought up before the Court of King's Bench to receive sentence on the 28th of October, 1618, and beheaded the next morning, in the 66th year of his age. His conduct after his committal to the Tower, and up to the moment of his death, was so calm and resigned, as to move the sympathy even of his enemies.

Of Sir Walter Raleigh's character and personal appearance, Aubrey says, 'he was a tall, handsome, and bold man; but his naeve was that he was damnable proud:' he had a most remarkable aspect, an exceeding high forehead, long-faced, and "sour eie-lidded, a kind of pigge-eie."' In an age of magnificence in dress, Raleigh was conspicuous for his splendour. Of an original and versatile genius, an eminent commander by sea and land, a navigator and discoverer of new countries, an accomplished courtier, a statesman, a proficient in the mechanical arts, a poet of no mean ability, Sir Walter Raleigh was one of the most remarkable characters of an age celebrated for its eminent men. Little can be said in favour of his moral character: he was crafty and rapacious, and his conduct was not regulated by truth and probity; but he had kindly affections, and was much beloved by his dependents. Besides his great work, he was the author of many smaller pieces on a variety of subjects, philosophical, political, naval, military, geographical, besides letters, and a collection of small poems. He had two sons by his wife; the elder was killed in South America; the second, Carew, who was born in the Tower, survived him.

RALEIGH-TOWN. [CAROLINA, NORTH.]

RALLIDÆ, a family of birds belonging to the *Grallæ* of Linnæus, *Grallatores* of Illiger.

Brisson placed the *Rails* in the first section of his seventeenth order, with the *Lapwings*, the *Jacana*, the *Pratincole*, &c.

The genus *Rallus* of Linnæus consisted of Rails properly so called; and the species in the last edition of the 'Systema Naturæ,' as left by him, were *Crex aquaticus*, *Porzana*, *fuscus*, *striatus*, *torquatus*, *Philippensis*, *Benghalensis*, *Carolinus*, and *Virginianus*. The genus is placed in the order *Grallæ* (the fourth), between *Parra* and *Psophia*.

Latham also gave it a place among the *Grallæ* (his seventh order), between the *Pratincole* and the *Jacana*.

Lacépède arranged *Rallus* among his *Oiseaux de Rivage*, in his thirty-third order (birds with a straight and compressed bill), between the genera *Ibis* and *Scopus*.

In M. Duméril's system *Rallus* is placed in the first family (*Pressirostres* or *Ramphostènes*) of his fifth order, *Echassiers*, between the *Jacanas* and *Oystercatchers* (*Hæmatopus*).

Illiger's *Macrodactyli*, belonging to his sixth order, *Grallatores*, include the genera *Parra*, *Rallus*, and *Crex*.

In Cuvier's fifth order, *Echassiers*, *Rallus* appears in its fifth family, *Macrodactyles*, between the *Kamichis* (*Palamedea*) and the *Fulicæ*.

M. Vieillot's second tribe (*Tetradactyli*) of his fourth order (*Echassiers*) includes, among many other families, the *Macrodactyles*, including the genera *Rallus*, *Porzana*, *Porphyrio*, and *Gallinula*. The *Macrodactyles* are placed between the *Macronyches* (*Jacana*) and the *Pinnatipèdes* (*Fulica*, *Phalaropus*, &c.).

M. Temminck places *Rallus* between *Scolopax* and *Gallinula*, in his thirteenth order (*Gralles*).

In M. de Blainville's system *Rallus* is also placed among the *Macrodactyles*, in the order *Grallatores*.

The late lamented Mr. Vigors, treating of the family *Scolopacidæ*, remarks that among the groups which originally composed the *Tringa* of Linnæus, the *Phalaropus* of Brisson may be distinguished, which, by its lobated feet and habits of swimming stands at the extremity of the *Scolopacidæ*, and leads the way to the succeeding family of *Rallidæ*. He then observes that the family of *Rallidæ*, composed of the Linnæan genus *Parra*, with its congeners, *Palamedea*, Linn., and *Chauna*, Ill., together with *Rallus*, Linn., and *Fulica*, Linn., corresponds with the *Macrodactyles* of Cuvier. He conjectures that *Chionis*, Forst., comes into this family; but he adds that he knows too little of the group to speak with any confidence. The Linnæan groups, he observes, are distinguished from the *Scolopacidæ* by their stronger bill and the greater length of the hind toe. They are also separated from the other birds of the order, and united among themselves, in his view, by the shape of their body, which is compressed and flattened on the sides, in consequence of the narrowness of their sternum. Mr. Vigors goes on to remark, that were we allowed to draw an inference from the zoological construction of other bodies, which move with the greater facility through the water in proportion as they assume this compressed and keel-like form, we might almost conclude that this structure, peculiar to the birds of the present family, facilitates their progress through that element, and is intended to counterbalance the deficiency in the formation of the foot, which separates them from the truer and more perfectly formed water-birds; and he alludes to Wilson's observation, who, when speaking of the *Rallus Virginianus*, mentions this character as conducive to the progress of the bird through the reedy marshes. 'It is certain,' continues Mr. Vigors, 'that the greater portion of these birds are excellent swimmers; and in such habits, as well as in the shortness of their *tarsi*, which is equally conducive to their powers in swimming, they are found to deviate from all the remaining groups of the order. They thus become an aberrant family, and lead directly, as has been before noticed, to the succeeding order of *Natatores*. The genus *Parra*, Linn., distinguished from *Rallus*, Linn., by the greater length of the toes, and more particularly by the length and straightness of the nails, is yet allied to that genus by the general structure of the bill. With *Parra* may be allied *Palamedea*, Linn., and *Chauna*, Ill., the *Parra chavaria* of the 'Systema Naturæ,' both of which seem to approach *Parra* in affinity, although the latter of them is so imperfectly known, that its situation cannot be decided with certainty. To *Rallus* succeeds *Crex*, Bechst., which, by its stronger and shorter bill, seems to lead on to *Gallinula*, Briss., from which genus, although agreeing with it in general appearance, it is decidedly separated from its terrestrial habits. *Gallinula* is set apart from the foregoing groups by the greater length of the toes and the dilatation of the upper mandible upon the forehead. This latter character is still farther developed in the ensuing genus *Porphyrio*, Briss., where the base of the bill exhibits a considerable degree of robustness; and is also carried on in *Fulica*, which immediately adjoins *Porphyrio*. The species that compose the true *Gallinula* and *Porphyrio* may be observed to possess a narrow membrane on each side of the toes, which extends along their whole length straight and entire. We thus recognise the gradual approximation of these genera to the lobated foot of *Fulica* and *Podoa*, which unite the swimming *Waders* to the true web-footed *Natatores*. The dilatation of the upper mandible into a flat crown upon the forehead, which characterises the latter groups of this family, together with the same length of the toes, is found to exist in some species of *Parra*; and thus we are led back to the groups from which we commenced our observations on the family.' Mr. Vigors then enters the family of the *Charadriadæ* by the genus *Hæmatopus*. (*Linn. Trans.*, vol. xv.)

The *Macrodactyles* of M. Latreille form the sixth family of his fourth order, *Echassiers*, and consist of the *Jacana*, *Kamichi*, and *Chauna*.

M. Lesson makes the *Rallusinées*, the fourth family, according to him, of the *Echassiers*, consist of the genera *Jacana* (*Parra*), *Palamedea*, *Chauna*, *Glareola*, *Rallus*, *Crex*, *Gallinula*, *Porphyrio*, *Podoa*, and *Fulica*. The *Rallusinées* are placed between the *Scolopacidæ* and the *Charadriadæ*.

Mr. Swainson observes that the *Rallidæ* comprise the rails and water-hens, and constitute a very natural and well-marked family in the order of Waders. They have been designated, he remarks, by these familiar names, from their peculiarly harsh notes, and from assuming much of the appearance of the gallinaceous or rasorial birds; another proof, he adds, that the true analogies of nature are often perceived by the vulgar, although passed over by the scientific. 'The most permanent differences,' says Mr. Swainson in continuation, 'in their structure, when compared with the foregoing families (*Tringidæ* and *Charadriadæ*), is the great size of the leg and the length of the toes, particularly the hinder one: the body is very thin and unusually flattened; a structure particularly adapted to the habits of Rails, since they live for the most part in the tangled recesses of those reeds and aquatic vegetables which clothe the sides of rivers and morasses. They are for the most part solitary and timid birds, hiding themselves at the least approach of danger, but quitting their semiaquatic retreats in the morning and evening, to feed in more open spots: their flight, from the shortness of their wings, is very feeble, but they run with swiftness; and by the peculiarly compressed form of their body, are able to make their way through dense masses of reeds and high grass with so much facility as to escape even after being desperately wounded. The flesh of all these birds is delicate; and from living chiefly upon aquatic seeds and vegetable aliment, they may be considered as aquatic *Gallinacea*. The following are amongst the most obvious genera or subgenera which enter into the present group. Of these the Jacanas (*Parra*) are the most singular; they are distinguished by toes of such remarkable length, that by covering an enormous circumference, these birds can walk upon aquatic plants floating on the surface of the water with as much ease and security as if they made their way over hard ground. Most of the species are armed with a short and formidable bony spur on the shoulder of the wings; and the head is either partially naked or furnished with fleshy wattles. Several species occur in the hot latitudes of America, Africa, and Asia, but the genus is unknown in Europe. It is probable that the typical characters of the family are best seen in the genera *Rallus*, *Crax* (Crex?), *Gallinula*, and *Fulica*. The purple water-hens are most beautiful and majestic birds, in size nearly as large as a fowl; they have a very thick and strong bill, the corneous front being continued over the fore part of the head like a helmet. There is a fine species found in the marshes of Sicily; and another, almost exactly resembling it, in the distant regions of Australia. The genus *Podoa* probably belongs to the next order (*Natatores*).' (*Classification of Birds*, vol. ii.)

In the synopsis of the same work, the *Rallidæ* are placed between the *Tantalidæ* and *Scolopacidæ*, and consist of the following genera: *Parra*, *Porphyrio*, *Fulica*, *Rallus*, *Gallinula* (with the subgenus *Alecthelia*).

The genera of *Rallidæ* (which family he places between the *Scolopacidæ* and the *Phaleropodidæ*), enumerated by Prince Lucien Bonaparte in his 'Birds of Europe and North America,' consist of *Aramus*, Vieill., *Rallus*, Linn., *Ortygometra*, Leach, *Gallinula* (Briss., *Stagnicola*, Br.), *Fulica*, Linn., and *Porphyrio*, Ray.

The *Rallidæ*, in Mr. G. R. Gray's 'List of the Genera of Birds,' are the fifth and last family of the *Grallatores*, and immediately preceded by the *Palamedeidæ* (which embrace the genera *Parra*, *Chauna*, *Palamedea*, and *Alecthelia*). The order *Natatores* follows.

The following are the subfamilies and genera of Mr. G. R. Gray's *Rallidæ*:—

Subfamily I. Rallinæ.

Genera.—*Ortygometra*, Ray (*Rallus*, Linn., *Porphyrio*, Briss., *Crex*, Bechst., *Gallinula*, Lath.).

Porzana, Vieill. (*Rallus*, Linn., *Gallinula*, Lath., *Zapornia*, Leach).

Rallus, Linn. (*Gallina* (Gallinula?), Ray).

Ocydromus, Wagl. (*Rallus*, Forst.).

Subfamily II.

Porphyrio, Briss. (*Fulica*, Linn., *Gallinula*, Lath.).

Gallinula, Ray (*Fulica*, Linn., *Hydrogallina*, Lacép., *Stagnicola*, Brehm).

Fulica, Linn.

Subfamily III. Heliornine.

Heliornis, Bonn. (*Plotus*, Gm., *Podoa*, Ill., *Colymbus*, Bodd.).

Podica, Less. (*Heliornis*, Vieill., *Podoa*, Boie, *Rhigelura*, Wagl.).

We proceed to notice some of the leading forms of this family.

Rallidæ.

Feet very large. Bill in general short, and greatly compressed. Tail excessively short, nearly hidden by the covers. Hinder toe elevated. (Sw.)

Parra.

Generic Character.—*Bill* straight, slender, moderate. *Feet* very long. Toes and claws of enormous length; the latter straight or recurved. *Carpus* generally armed with acute spurs. (Sw.)

Mr. Swainson remarks that the *Jacanas* or *Parræ* are wading birds, somewhat analogous, both in structure and habits, to the European Water-hen; but in their native haunts, from not being disturbed, they are less shy. 'The number of these birds,' says Mr. Swainson, 'on the lakes of Brazil, the elegance of their movements, and their fearlessness of man, excite an interest in the traveller who journeys through regions ornamented alone by nature. They are very light birds, and their long toes spreading over a wide surface enable them to walk on the floating leaves of aquatic plants with as much facility as if they were on land. In such situations their appearance is really delusive; for their pressure being sufficient to sink the surrounding leaf just below the surface, the birds actually appear to walk upon the water.' (*Zool. Ill.*, 2nd series.)

Geographical Distribution of the Genus.—Numerous in South America; some in India; and a few in Africa.

Example, *Parra Africana.*

Description.—Deep cinnamon above; crown of the head naked; throat white; breast fulvous; neck and quills black, spur on the wing obsolete.

Localities.—Africa, Abyssinia (Bruce), Mozambique (Salt), Western Africa (Swainson, on the authority of Ward), South Africa (Smith).

The strong bony spur with which the wing is armed in the typical species, becomes so small in *Parra Africana*, that it is hardly perceptible when the wing is closed. In another African species, *Parra Capensis*, the spur or spine has become a small tubercle. The African Jacanas may therefore be referred to the aberrant group of this genus. Dr. Smith only met with one individual of *Parra Capensis*, and he strongly suspects that it was in immature plumage. It was killed while seeking for its food upon some water-plants which coated the surface of a small river near Algoa Bay, and he has figured the bird standing on the leaf of a water-lily. He notices *Parra Africana* as the only other species of the group which has yet been found in Southern Africa, and states that it never ranges so far to the westward as the Cape Colony, though it is often found to the westward of Port Natal.

Parra Africana.

Porphyrio.

Generic Character.—Bill short, strong, high; the base dilated into a flat plate on the front of the head; the culmen arched. *Nostrils* large, basal, covered by a membrane, naked; the aperture terminal and oval. *Feet* very large. Toes without any lateral membrane. Claws large, slightly curved. (Sw.)

M. Temminck states that the *Porphyriones* live nearly like the Water-hens, to which they are the most closely approximated: like them, their habitual haunts are the fresh-waters; but the immense rice-fields (rizières) and marshes of the south equally serve them for an asylum and retreat. More inclined by their appetite to cereal grains and plants, than aquatic herbs, the Porphyrios frequent the land more than the Water-hens: they move with grace on the water, and run with elegance and swiftness on the land or over the plants which grow in the water. Their body is not so compressed nor so slender as that of the water-hens; their formidable bill, composed of a very hard substance, and nearly without a nasal fossa, which is covered by a membrane, serves them as an instrument for cracking the husks of grains and breaking the hardest stems; their feet, which they use to seize their food and convey it to their bill, are provided with very long toes, easily retractile, and with nails which bend also with some facility, which gives them a power of prehension.* A brilliant plumage, where blue or a turquoise hue predominates, clothes the greatest number of the known species.

It is not clear what species of this genus was known to the antients, who held it in high estimation. The *Porphyrio* does not appear to have been sought after for any other purpose than that of keeping it alive; indeed Ælian states that he never heard of one being served at any banquet. Pliny (*Hist. Nat.*, x. 46 and 49) speaks of the Porphyrios as 'laudatissimi in Comagene,' and says that their bill and long legs are red; the Balearic Islands are also named by him as a place whence they were sent to Rome. He speaks of their peculiar mode of drinking, their soaking their food in water and raising it to their bills in their claws: 'Bibunt aves suctu, ex his quibus longa colla, intermittentes, et capite resupinato velut infundentes sibi. Porphyrio solus morsu bibit, idem est proprio genere, omnem cibum aqua subinde tingens, deinde pede ad rostrum veluti manu afferens.'

But there was another quality which was supposed to reside in the *Porphyrio*, which made it both a highly prized and dangerous inmate. The bird was considered as a kind of guard over the women of the house in which it was domiciled: it was believed that it took notice of adultery, and that if the crime was committed, it would give notice to the master of the house by making signs as if it wished to strangle itself. It is to this that the old quatrain alludes in the 'Portraits d'Oyseaux:'

'Porphyrion declare l'adultere
Fait au logis auquel on l'entretient:
Car à ces fins tous les semblans il tient
De se vouloir estrangler et deffaire.

Though, as we have observed, it is not certain what particular species was known to the antients, indeed there appears to have been more than one, we do not know why *Porphyrio hyacinthinus*, which, as we shall presently see, is very common in Sicily, and has a very wide range, should not have been kept in a state of domestication by them.

Example, *Porphyrio hyacinthinus* (*Pollo Sultano*, Savi).

Description.—(Both sexes.)—Bill fine red; legs and feet fleshy red; irides lake-red; cheeks, throat, sides of the neck, and chest turquoise-blue; remainder of the plumage deep dull indigo-blue, having the edges of the greater and lesser coverts of the wings lighter in colour and more brilliant; under tail-coverts white. (Gould.)

Young of the Year.—Belly, till the month of October, white; occiput yellowish-brown; median part of the head whitish; mantle bluish-ash. Feet reddish-olive. At the time of the moult, which takes place towards the end of October, individuals are found in a state of transition from the livery of youth to that of the adult: early in May the rich blue plumage is complete. (Temm.)

Geographical Distribution.—'Independently of the southern and eastern parts of Europe, the marshes of which are the places of constant resort for this beautiful bird, its range is extended,' says Mr. Gould, 'over a great portion of Africa to the south, and as far as the mountains of the Himalaya to the east. In Europe it is especially abundant in the Grecian Archipelago, the Levant, and the Ionian Islands: it is less common in Dalmatia and Sardinia. The southern provinces of Hungary and Russia and the borders of the Caspian Sea may also be enumerated among its European localities.' M. Temminck states that it is to be seen in many cities of Sicily (where, according to M. Cantraine, it is very common in the neighbourhood of Lentini), that it is not known in Dalmatia nor Calabria, and is rare in Sardinia; and that it is known in Catania under the name of *Gallo-fagiano*.

Food, Habits, Reproduction, &c.—Mr. Gould states that, like the Water-hen or Common Gallinule, this species dwells on the borders of rivers and in all marshy situations. In its food, he tells us, it is partly herbivorous, feeding on various kinds of marine vegetables; still, as the robust and hard character of its bill implies, it prefers hard seeds and grain, to which are added snails, frogs, and other aquatic animals.

'Although its form,' continues Mr. Gould, 'would seem to deny the fact, its actions and appearance on the land are both elegant and graceful. It is extremely quick in all its movements, running with ease and swiftness; and from the great expansion of its feet, it is enabled to pass with facility over soft oozy mud, aquatic herbage, &c.; but although much agility characterises this species on land, its aërial evolutions are heavy, and apparently performed with considerable difficulty.' M. Temminck states that it lives in the marshes where the water is not deep, and that its stupidity is such that when closely pursued it buries its head in the mud. M. Verneuil informed him that solitary individuals are sometimes found in Dauphiné: that of the museum of Grenoble was, he adds, killed in the marshes of Burgundy.

Porphyrio hyacinthinus breeds in marshes, much in the manner of the Common Gallinule, giving preference to the sedgy parts of the morass and partly inundated rice-fields, where it constructs a nest of aquatic plants, and lays three or four white and nearly round eggs. (Gould.)

Porphyrio hyacinthinus.

Fulica.

Generic Character.—Bill as in *Porphyrio*, but more slender; the base straight; the gonys short and angulated. *Feet* very large; the toes margined with a lateral membrane, which is either narrow and of equal breadth or dilated into lobes. The natatorial type. (Sw.)

Example, *Fulica atra*.

Description.—Head and neck deep black; upper parts slaty-black; all the lower parts bluish-ash; frontal plate very wide, pure white; bill white, slightly tinged with rose-colour; iris crimson-red; feet ash-colour, tinged with greenish, but of a yellow or greenish-red above the knee.

The sexes do not differ, excepting that in the female and the young the frontal plate is less developed, and that in the latter, after the autumnal moult, the lower parts are slightly tinged with reddish. Before the moult, the frontal plate of the young is hardly apparent, and that and the bill are greenish-ash; all the lower parts are whitish-ash: in this state it is, according to M. Temminck, *Fulica Æthiops*, Sparm.; Gmel.

Varieties.—Pure white (very rare), or whitish with the colours weakly shown. Wings white; all the rest of the plumage as in ordinary. It is then *Fulica Leucorix*, Sparm.; and Gmel.

Fulica atra is the *Foulque*, *Macroule*, or *Morrelle* of the French; *Schwarzes Wasserhuhn* of the Germans; *Meir Koet* of the Netherlanders; *Folaga* and *Folacra* of the Italians; *Blas-klacka* of the Swedes; *Vand-Hoene* and *Bles-Hoene* of the Danes; *Jâr ddwfr foel* of the antient British, and *Coot* of the modern British. Some have thought that it is the κίπφος (Cepphus) of Aristotle,—quære tamen.

Geographical Distribution.—Europe, in marshes, lakes, and gulfs; very abundant in Holland and in the lakes of the interior of France; less numerous in Germany and Switzerland. Dr. Von Siebold and M. Bürger saw it in Japan.

Habits, Food, Reproduction.—'The coot,' says Mr. Gould, 'is indigenous to our islands, residing on all large sheets of water, but giving preference to those overgrown with rushes and margined with a belt of thick reeds and luxuriant vegetation.' Such is the meer or pond before William of Wykeham's palace at Bishop's Waltham, where they abound. In such haunts it builds, early in the spring, a strong and solid nest of rushes, grasses, and water-plants. The large nest thus constructed rises above the surface of the water, on the bottom of which, when shallow enough, the base of the nest sometimes rests. Its more frequent situation however is in the reedy and rushy tufts and rank vegetation of the water's edge, so as to be concealed. The eggs, which are brownish-white, spotted with dark brown, range from seven to ten in number. The young, when hatched, are clothed in a black down, and take water very soon. As winter approaches, the coots seek the open waters near the sea, and the mud-flats at Southampton are among the places visited by them in great numbers. The coot swims and dives admirably, but flies heavily and with effort. Its food consists of worms, slugs, aquatic plants, insects, &c.

Much cannot be said for it as an article of food, except when it is young, and then it requires much perseverance to get off the black down next to the skin.

Fulica atra.

Gallinula.

Generic Character.—*Bill* short, straight; the margins not inflexed. The cutting edges of the upper mandible folding over the lower. Gonys very short, angulated. Toes simple, without any marginal membrane. The rasorial type. (Sw.)

M. Temminck remarks that the Water-hens have their body very much compressed throughout its length. They live on land, but, like the *Ralli*, haunt fresh-waters. They swim with considerable celerity, dive with facility, run very fast on land, even where the herbage and reeds are thickest, and often, like the *Rails*, over the leaves and plants that grow at the surface of the water. Their food, like that of the *Rails* also, consists of insects and vegetables. They undergo perhaps a double moult, but the colours do not change. The young differ much from the adult; the plumage of the first does not attain its permanent colours till the expiration of a year. The males are only distinguished from the females by purer tints, and the frontal plates of the former are more extended.

Example, *Gallinula chloropus.*

Description.—(*Old Male.*)—Head, throat, neck, and all the lower parts slaty blue; upper parts deep olive-brown; external border of the wings, large longitudinal spots on the sides, and lower coverts of the tail, pure white; three or four of the feathers placed at the centre of the tail-coverts deep black; base of the bill and large frontal plate bright red, point of the bill yellow; iris red; feet yellowish-green; on the tibia a naked circle of a fine red.

Old Female differs only in having the tints of the plumage a little less bright.

The Young, till their second autumnal moult, differ much from the old. The top of the head, the nape, the back, and rump are olive-brown; quills deep brown, terminated by bright brown borders; tail deep brown; throat, front of the neck, and a spot below the eye whitish; rest of the lower parts bright grey; point of the bill olive-green, blending into olive-brown at the base; iris brown; feet olive, but tinged with yellowish on the tibia.

Young of the Year.—More of the whitish around the bill; and the lower parts with the tints less bright. Individuals in a state of transition from one period of age to another have the frontal plate more or less large, coloured with red or yellowish.

Such is M. Temminck's description, but Mr. Gould (*Birds of Europe*) says, 'One circumstance respecting this familiar bird appears to have escaped the notice of most ornithologists: we allude to the fact of the female being clothed in a dark and rich plumage, and having the base of the bill and the frontal shield of a bright crimson-red tipped with fine yellow; her superiority in these respects has caused her to be mistaken for the male, which, contrary to the general rule, is at all times clothed in a duller plumage, and has the upper surface more olive than in the female; the bill is also less richly tinted. We were first led to notice this fact in consequence of observing the birds sitting or rising from the nest to be those whose richly coloured bills had induced us to believe them to be males, and which the dissection of a great number of individuals has now fully proved to us to be the females. Besides this difference, the sexes vary in size, the female being about one-fifth less than her mate.' The same author states that the young are clothed with a black down, and during the first autumn, although equal to the adults in size, have a much lighter plumage, the whole of the throat and under surface being then greyish white, and the bill and legs olive. The male has the bill red at the base, strongly tinged with olive; the centre of each feather on the flanks is blotched with a large oblong patch of white, which is the colour of the under tail-coverts; irides red: tarsi and toes greenish olive: the former being encircled with a red mark immediately above the tarsal joint, called the *garter*.

This bird in its different states of plumage is the *Poule d'eau* of the French; *Gallinella* of the Italians; *Wasser-huhn*, *Grünfüssige Rohrhuhn*, and *Braune Meerhuhn* of the Germans; *Common Gallinule*, *Waterhen*, or *Moor hen* of the modern British; and *Dwfriar* of the antient British.

Geographical Distribution.—Very wide. Mr. Gould states (and he is confirmed by others), that this species appears to be not only dispersed over the whole of Europe, but extends its range over the greater portion of Africa and India; and, like the Peregrine Falcon and Barn Owl, may be said to be universally distributed over the globe: 'it is even questioned,' adds Mr. Gould, 'whether those from tropical America, China, and the islands of the Pacific, which exhibit the most trifling marks of difference, should not be considered as identically one and the same species.' It was seen by Dr. Von Siebold and M. Bürger in Japan, and M. Temminck remarks that the African variety, which is also found in the isles of Sunda, has the anterior border of the wing reddish; the lower tail-coverts, which, in European, Asiatic, and Japanese individuals, are of pure white or Isabella colour, have a reddish tinge in the variety from Africa and the Sunda Isles, which is also somewhat less than European and Japanese birds, and has the frontal plate larger. The variety from the Sunda Isles is, according to M. Temminck, *Gallinula Orientalis* of Horsfield (*Linn. Trans.*, vol. xiii.). The only difference between the Japanese bird and that of Europe is the Isabella tint of the lateral under tail-coverts in the former: in the European variety those feathers are white.

Habits, Food, Reproduction, &c.—In our islands the haunts of the common Gallinule are rivers, meers, ponds, sedgy spots, and marshy places. The nest is formed of interlaced flags, weeds, &c., generally in the most concealed parts of the rushy rivulet or sedgy margined pond, and in it from five to nine pale yellowish-brown eggs spotted with red are deposited. Incubation continues for three weeks. The young are exposed to many enemies, for their parent has not only to guard them against birds of prey and the smaller carnivora, rats, &c., but against the attacks of the pike. The food consists of aquatic insects, mollusks and worms, seeds and water herbage. The flesh of a water-hen in good season, after having had the advantage of a neighbouring wheat or barley stubble, is well flavoured, juicy, and sapid. The sportsman who is not well acquainted with their habits, often leaves them behind perched among the boughs of the trees or shrubs that overhang the water or closely adjoin it; for these birds when hard pressed not uncommonly get up into such retreats till the danger is passed. On its feet it is lively and not ungraceful: on wing it is heavy and slow.

Some of the African Gallinulos, figured by Dr. Smith (*Gallinulæ dimidiata* and *Jardinii* for instance), present certain differences which would appear to warrant subgeneric distinction.

Gallinula chloropus.

Rallus.

Generic Character.—*Bill* lengthened, slender. Both mandibles in general slightly curved, and with their margins considerably inflected beyond the nostrils. The tenuirostral type. (Sw.)

Example, *Rallus Aquaticus*.

Description.—Throat whitish; sides of the head, neck, breast, and belly leaden ash-colour; all the feathers of the upper parts red-brown, marked in the middle with deep black; sides deep black transversely striped with white bands; lower coverts of the tail white; bill red but clouded with brown at the point and above; feet brown flesh-colour; iris orange.

The Young of the Year have the middle of the belly of a red-brown, and the abdomen is blackish-ash without the white bands. (Temm.)

Mr. Gould remarks that the sexes are alike in plumage, but that the male is generally the largest. M. Temminck observes that they undergo a double moult, but that there is no marked difference between the two liveries.

This species is the *Rale d'Eau* of the French; *Porciglione*, *Merla aquarola*, and *Merla d'Acqua* of the Italians; *Wasser Ralle* of the Germans; *Water-rail*, *Bidcock*, *Bilcock*, *Velvet-runner*, *Brook-runner*, and *Brook-Ousel* of the modern British; and *Cwtair* of the antient British. It is the *Rasle noir* of Belon, who gives the following synonyms:—'Ορτυγομήτρα† (Ortygometra), *Matrix Cothurnicum*, *Ralla*, *Rasle*, *Rulle*, *Roy et mere des Cailles*, and *Re de Quaglie*.

† Aristot., 'Hist. Anim.,' viii., c. 12.

Geographical Distribution.—Europe, over which it is dispersed generally, but it is is more particularly abundant in the low districts of Holland, Germany, and France. In our islands it is more plentiful than is generally believed from its very shy and retired habits. Dr. Von Siebold and M. Bürger saw the bird in Japan.

Habits, Food, Reproduction, &c.—'Except when closely pressed,' says Mr. Gould, 'the Water-Rail seldom takes to flight, but evades pursuit by quietly yet quickly traversing the bottoms of thickset reed-beds and banks overgrown with luxuriant vegetation bordering the sides of pools and ditches, where it finds a covert through which its slender and compressed form enables it to pass with the greatest facility; besides which it possesses the power of swimming and diving, both of which materially aid its escape. Without denying the possibility of this bird being migratory, we have the strongest reason to believe that numbers remain with us during the whole of the year, frequenting during the summer season fen-land, morasses, ponds, and ditches, about which it incubates; resorting, on the approach of winter, to the sides of our large streams and rivers. Its nest is composed of rushes and vegetable fibres closely concealed among herbage, at a little elevation from the water; its nidification in fact closely resembles that of the Moor-hen. Its eggs* are of a yellowish-white colour, marked with spots of red-brown. Its food consists of worms, snails, soft insects and their larvæ, which abound in swampy places; vegetable substances also form a part. The young, when first excluded from the egg, are covered with black down, and are observed to be in perfect possession of the powers of swimming, and providing for their own safety and subsistence, remaining however under the parent's care and protection.'

The Water-rail is a delicious bird for the table. The writer of the old quatrain in the 'Portraits d'Oyseaux,' thus alludes to its celerity in running:—

'Le Rasle noir par les ruisseaux habite,
Et est cogneu en diverse contrée
D'un bon coureur la vistesse est monstrée,
Quand on le dit, comme un Rasle, aller viste.'

Rallus aquaticus.

Crex.

Generic Character.—*Bill* shorter than the head, thick at the base, subcultrated, compressed; the culmen gradually deflecting from the forehead to the point of the bill; lateral furrow of the upper mandible broad, and occupying more than half its length; angle of the under mandible bending upwards; both mandibles of an equal length. *Nostrils* concave, lateral, linear-ovoid, pierced in a membrane occupying the mandibular furrow in the middle of the bill. *Wings* armed with a spine, and having the second and third quill-feathers the longest. *Plumage* soft, thick, and open in texture. Legs strong, of mean length, with the lower part of the tibiæ naked. *Feet* fourtoed, three before and one behind. *Toes* long, slender, and cleft to their base, without any lateral membrane, hind toe resting on the ground. Claws arcuate, compressed, and pointed. (Selby.)

Mr. Selby remarks that the *Crakes* hold an intermediate

* From six to ten. Tem.

station between the *Rails* on the one hand and the *Gallinules* on the other, from the first of which they are distinguished by a shorter, thicker, and more angular bill, and from the latter in wanting the extension of the lateral membrane that borders the soles of the toes, as well as the naked callous skin (or plate) that occupies the forehead. By Linnæus, he observes, they were included in his genus *Rallus*, but Latham afterwards, under his system, transferred them to the genus *Gallinula*, in which he has been followed by Temminck. Mr. Gould has also placed the Land-Rail (*Rallus Crex*, Linn.) under *Gallinula*, but with regard to the smaller and spotted Crakes he has adopted Leach's generic name of *Zapornia*, which is supposed to be a transmutation of *Porzana*, *Rallus Porzana* being the Linnean name of one of those species. Bechstein separated the Crakes from *Gallinula* and *Rallus*, under the generic name of *Crex*, which included the *Spotted Crakes* (*Zapornia*), and many ornitholcgists have adopted his view. Mr. Selby, who is one of those who follow Bechstein, states that the habits of the Crakes are similar in many respects to those of *Gallinula* and *Rallus*, the former being of a shy and solitary disposition, living concealed in the thick herbage of meadows or marshy districts. 'They have,' says Mr. Selby, 'the same thin and compressed shape of body, and they run with a skulking gait, and with great quickness, seldom taking wing unless suddenly surprised, or when forced to it by persevering pursuit, of course with the exception of the times of their annual migration. They feed on worms and insects, as well as vegetables and seeds. Their flight is awkward and heavy, and they hang their legs, when only on wing for a short distance. All the British species are migratory, and come under the designation of summer visitants. The plumage of both sexes is nearly alike, differing only in the colours of the male bird being purer and brighter in tint. The young however are very different, and do not acquire the matured plumage till they undergo the second general moulting.'

Example, *Crex pratensis*, Bechst. (*Rallus Crex*, Linn.).

Description.—A large ash-coloured eyebrow, prolonged upon the sides of the head; all the feathers of the upper parts blackish brown in the middle, bordered laterally with ash-colour, and terminated with reddish; the long feathers which extend on the quills entirely bordered by a large band of olive-reddish; coverts of the wings of a rusty red; quills reddish externally; throat, belly, and abdomen white; breast olive-ash; sides reddish, striped with white; upper mandible brown, lower whitish; iris reddish-brown; eyebrows flesh-colour; feet flesh-colour or reddish-brown.

The *Young* have the tints less vivid, but brighter, with some white spots.

This is the *Rale de Genet*, or *Roi des Cailles* of the French; *Re di Quaglie* of the Italians; *Wiessen-Knarrer* and *Wachtel-König* of the Germans; *Kwartel Koning* of the Netherlanders; *Vagtel-Konge*, *Aker-Rixe*, and *Skov-Snarre* of the Danes and Norwegians; *Land-Rail*, *Corn-crake*, *Daker-hen*, *Bean-crake*, and *Corn-drake* of the modern British; and *Rhegen yr yd* of the antient British. Belon gives the following synonyms:—'Ορτυγομήτρα ἄλλη, *Ortygometra altera*, *Ralla*, *Re de Quaglie*, *Ralle rouge*, or *Ralle de Genet*.

Geographical Distribution.—'The Land-rail,' says Mr. Gould, 'appears to be extensively spread over the whole continent of Europe; it is very abundant in Holland, and not uncommon in France and Germany. It is a migratory species, arriving with us about the latter end of April or the beginning of May, when it scatters itself in pairs over the whole of the British Isles.'

Food, Habits, Reproduction, &c.—Worms, snails, insects and their larvæ, seeds, and grain form the food of the Land-rail. It is very fond of grasshoppers. 'Its habits,' says Mr. Gould, 'are extremely shy and retiring, selecting for its places of abode grassy meadows, fields of young corn, ozier-beds, and marshy grounds, seldom allowing itself to be seen; and were it not for the peculiar note of the male, which consists of a singular grating monotone—sometimes sounding as if beneath one's feet, and again appearing as if uttered at a distance,—its presence would not be betrayed. In these its favourite places of resort and concealment it carries on the process of incubation, constructing its nest on the ground, and occasionally on small hillocks, the nest being composed of slender flags or grasses; the female laying from eight to twelve eggs, rather less than those of the moor-hen, to which, in the markings, they bear some resemblance, of a yellowish-white, covered with dull rust-coloured spots. The young when hatched are covered with a blackish down, and are soon able to follow the parent birds, attaining, by the commencement of the shooting-season, nearly the adult size and plumage.' Its southward migration commences in October, when it passes over to the Continent.

After it is once flushed, it is almost impracticable to force the Land-rail to take wing a second time, until it has run through every part of the cover that holds it. It is easily shot when on wing, though its flight is generally very short, for it flies heavily, and with the legs hanging down. It will run before a dog with the greatest rapidity, and very frequently escapes by trusting to its legs alone.

When dressed on the same day on which it is killed, with the trail in, it is very delicious, and it has always been highly esteemed for the table.

In the old quatrain under the cut of the Land-rail we read,—

'Au Ralle noir est ressemblant ce Ralle,
Sinon de bec, de grandeur et coleur.
A la Perdrix il ne cede en valeur,
Mesme leur chair est en bonté egale.'

In the 'Northumberland Household-Book,' *Reys* are among the birds admitted to his lordship's table, and are charged at twopence each, the same price as that of a quail, and double that of a teal. Drayton too, in his 'Polyolbion' (twenty-fifth song), notices—

'The Rayle, which seldom comes but upon rich men's spits.'

Crex pratensis.

The reader will find the other European Crakes beautifully figured in Mr Gould's grand work 'The Birds of Europe;' of these, *Zapornia Baillonii* and *pusilla* were observed by Dr. Von Siebold and M. Bürger, in Japan.

RALPH, JAMES, was born at Philadelphia, in what year is not recorded, and passed the earlier part of his life there as a schoolmaster. In 1725 he came to England in company with his townsman Benjamin Franklin. 'We have not learned,' says the writer of his article in the 'Biographia Dramatica,' 'what was then the immediate object of his pursuit, but it was probably something in the public offices dependent on the court; for he soon became a frequenter of the levees, and attached to some great men to whom his abilities recommended him.' It may be doubted notwithstanding if he had any other employment for some time except writing in the newspapers. In the first book of the 'Dunciad,' published in 1728, Pope mentions him as one of the 'gazetteers,' who are described in a note as 'a band of ministerial writers, who, on the very day their patron (Walpole) quitted his post, laid down their paper, and declared they would never more meddle in politics.' The lines in the text are—

'And see, thy very gazetteers give o'er,
Even Ralph repents, and Henley writes no more.'

This same year appeared Ralph's first separate and acknowledged literary performance, a poem, entitled 'Night.' It is to this work that Pope alludes in the third book of the 'Dunciad,' where he exclaims—

'Silence, ye wolves, while Ralph to Cynthia howls,
And makes night hideous; answer him, ye owls!'

To this passage is appended a very abusive note, in which Ralph, whose name is stated to have been inserted after the first editions of the poem, is denounced as the author of 'a swearing piece called "Sawney,"' which, it appears, was an attack upon Pope and his two friends Swift and Gay. 'This low writer,' it is added, 'attended his own works with panegyrics in the journals, and once in particular praised himself highly above Mr. Addison, in wretched remarks upon that author's account of English poets, printed in a London journal, September, 1728. He was wholly illiterate, and knew no language, not even French. Being advised to read the rules of dramatic poetry before he began a play, he smiled and replied, 'Shakspere writ without rules.' He ended at last in the common sink of all such writers, a political newspaper, to which he was recommended by his friend Arnall [manager of the 'British Journal'], and received a small pittance for pay.' In reply to this, his admirer in the 'Biographia Dramatica' says, 'It is very certain that he was master of the French and Latin languages, and not altogether ignorant of the Italian; and was in truth a very ingenious prose writer, although he did not succeed as a poet.' His dramatic writings are—'The Fashionable Lady, or Harlequin's Opera,' produced at the theatre in Goodman's Fields, in 1730, with some success, in the rage for such entertainments which had been recently excited by the 'Beggar's Opera;' 'The Fall of the Earl of Essex,' a tragedy (altered from the 'Unhappy Favourite' of John Bankes), brought out at the same house in 1731; the 'Lawyer's Feast,' a farce, performed at Drury Lane in 1744; and the 'Astrologer,' a comedy, 'once acted,' says the title-page, 'at Drury Lane,' also in 1744. 'The Astrologer' was only an alteration of an old play, called 'Albumazar,' written by a Mr. Tomkis, of Trinity College, Cambridge, in 1615. 'Ralph, in his advertisement,' says the 'Biographia Dramatica,' 'complains that ten years elapsed before it could obtain the favour of a representation; that he was not unknown to the great, nor destitute of private friends; and having devoted the most serious of his studies to the service of the public, he had some reason to expect the public favour; yet that the receipts of the house upon the first night were but twenty-one pounds; and when the manager risked a second, to give the author a chance for a benefit, he was obliged to shut up his doors for want of an audience.' Both the play and Ralph's dramatic reputation would thus appear to have been very bad. Another of his latter publications, which is described as 'a very excellent and very entertaining performance,' a tract, entitled 'The Case of Authors,' is stated to have also had 'some relation to the stage;' it was probably an argument for the protection of dramatic copyrights; though his own do not seem to have been in much danger of infringement.

Most of Ralph's publications however were political pamphlets on the topics of the day; and he is also supposed to have continued to be an active contributor to the public journals to the end of his life. He attached himself latterly to the faction of the Prince of Wales, and frequent mention of him may be found in Bubb Dodington's 'Diary.' Horace Walpole, in his 'Memoirs of the Last Ten Years of George II.,' writes, under date of 2nd of June, 1753:—'A new anti-ministerial paper appeared, called "The Protester," supported at the expense of the duke of Bedford and Beckford [the alderman], and written by Ralph, a dull author, originally a poet, and satirised in the 'Dunciad;' retained, after his pen had been rejected by Sir Robert Walpole, by Dodington and Waller; but much fitter to range the obscure ideas of the latter than to dress up the wit of the former: from them he devolved to the Prince of Wales in his second opposition, and laboured long in a paper called 'The Remembrancer,' which was more than once emboldened above the undertaker's pitch, by Lord Egremont and others. Ralph's own turn seemed to be endeavouring to raise mobs by speculative ideas of government; from whence his judgment at least may be calculated. But he had the good fortune to be bought off from his last journal, the 'Protester,' for the only paper that he did not write in it.' Other accounts make him to have been 'taken off' by a pension towards the end of Sir Robert Walpole's time, in consequence of having then made himself so formidable to the ministry. The death of Prince Frederick (in March, 1751) was an annihilating blow for the moment to Ralph, as well as to his patron Dodington, who had promised to make him his secretary if he should live to have the seals of secretary of state for the southern department, which the prince had engaged to give him (*Diary*, July 18 and 19, 1749); but it is said that he obtained a considerable sum from the government for the surrender of an important manuscript written by the prince, or under his royal highness's direction, which had come into his possession. On the accession of George III., he got another pension, which however he did not long enjoy, for he died of gout at his house in Chiswick, 24th January, 1762, followed in a few weeks by his only daughter, in her eighteenth year, of the same disease. Ralph had more talent and perhaps more principle too than the hostile notices we have quoted would allow him. Of his political pamphlets, the only one which is now remembered is his answer to the duchess of Marlborough's famous 'Account of her Conduct,' an octavo volume of four hundred and sixty-seven pages, entitled 'The Other Side of the Question, or an Attempt to rescue the Characters of the Two Royal Sisters, Queen Mary and Queen Anne, out of the hands of the D—— D—— of ——, in which all the Remarkables in her Grace's late Account are stated in their full strength, and as fully answered; the conduct of several noble persons is justified; and all the necessary lights are thrown on our Court history from the Revolution to the change in the ministry in 1710: in a Letter to her Grace, by a Woman of Quality,' Lond., 1742. This is by far the ablest and most important of the various answers and defences which her grace's publication drew forth; and some things in it appear to have been supplied by the family of the late earl of Oxford (the lord-treasurer Harley). Ralph is also the author of another anonymous work (published indeed without the name of either printer or bookseller) entitled 'Of the Use and Abuse of Parliaments; in Two Discourses, viz. 1, A General View of Government in Europe; 2, A Detection of the Parliaments of England from the year 1660,' 2 vols. 8vo., Lond., 1744. In an advertisement we are informed that the first of the two discourses, which however fills only seventy-eight pages of the first volume, is from the pen of Algernon Sydney. The rest of the book is a hasty performance, and of little value. But his principal work, also anonymous, is his continuation of Guthrie's History, entitled a 'History of England during the Reigns of King William, Queen Anne, and King George I.; with an Introductory Review of the Reigns of the Royal Brothers, Charles and James; in which are to be found the seeds of the Revolution. By a Lover of Truth and Liberty;' 2 vols. fol., Lond., 1744-46. Notwithstanding a systematic and very unfair depreciation of King William, which runs through a great part of it, this work is written with considerable spirit and acuteness, and contains many new facts and corrections of the views of preceding historians. It has decidedly risen in reputation with our increasing knowledge of the times of which it treats.

RAM. [SHEEP.]

RAMA. [VISHNU.]

RAMADHA'N, the ninth month in the Arabian calendar, and a sort of Lent observed by the Mohammedans, in obedience to the express command of the Koran. During this month every good Moslem is bound to fast from the first appearance of day-break until sunset. He must abstain from eating, drinking, smoking, smelling perfumes, and all other unnecessary indulgences or pleasures of a worldly nature; even from intentionally swallowing his spittle. He is allowed to bathe himself, but it is on condition that he is not to plunge his head under water, lest some drops should enter his mouth or ears. Some even are so scrupulous that they will not open their mouths to speak, for fear of breathing the air too freely. To make amends for this extreme rigour, Moslems generally feast all night till day-break, though the more rigid begin the fast again at midnight. As the Ramadhán happens at different seasons of the year, the fast is very severe when it falls in summer; the abstinence from drinking being most painfully felt. Persons who are sick, or on a journey, and soldiers in time of war, are not obliged to observe the fast during this month, but then they should fast an equal number of days at a future time. Fasting is also dispensed with in the case of nurses and pregnant women. The prophet even disapproved of any persons keeping the fast of Ramadhán, if not perfectly able; and he desired no man to observe it so strictly as to injure his health or disqualify himself for necessary labour, which is frequently the case among the lower classes of people. The reason given by the Mohammedan theologians for the month of Ramadhán having been fixed upon for this purpose is, that the prophet received his first revelation in that month; others pretend that it was chosen by Mohammed from its being generally spent by the antient Arabs in revelry and mirth and excessive drinking.

RAMÂYANA. [SANSCRIT LITERATURE.]

RAMAZZI'NI, BERNARDO, was born at Carpi, near Modena, in 1633. He studied medicine at Parma, and took his doctor's degree there in 1659. He practised successively at Carpi and at Modena; and when the university of the latter place was instituted, he was appointed professor of the theory of medicine by the duke Francis II. In 1700 he was invited to the second professorship of medicine at Padua, and in 1708 was raised to the principal chair there, though blind and so infirm that he earnestly desired to decline that honour. He died in 1714.

Ramazzini was a frequent writer and a very warm controversialist both in medical and literary subjects. His first work was a series of letters in a controversy with Moneglia, a physician of Modena, in which both engaged with much more acrimony than medical judgment, but in which Ramazzini certainly supported the best view of the case, which respected the removal of the placenta after childbirth.

The works by which Ramazzini is now best known are 'De morbis artificum diatriba,' Mutin., 1770, and 'De abusu chinæ-chinæ diss. epist.' The former was translated into several languages, and among them into English in 1725. It contains a fair description of all the diseases to which each class of artificers is liable, as far as they were then known, the descriptions being very carefully drawn up both from the writings of his predecessors and from his own observations. The latter was intended to detract from the extravagant reputation which the Peruvian bark at that time enjoyed, and though it may now be evident that the author fell into the opposite extreme, and degraded that medicine far below its real merits, the work was probably in its day productive of much benefit. The whole of Ramazzini's writings were published collectively at Cologne, in 1689, at London in 1717, and at several other places at nearly the same time. They are still held in high repute by the Italian physicians, who seem to regard their author with as much reverence as they did, who in his life-time honoured him with the title of Hippocrates III.

RAMBEH, the Malay name of a fruit described by Mr. Jack as being common in the peninsula of Malacca, but unknown at Bencoolen, while the *Choopa*, which is nearly allied to it, is abundant at the latter, but is not found at the former place. The fruit is that of a tree called *Pierardia dulcis*, of the natural family of Sapindaceæ. Another species of the same genus is called *P. sapida*, from its also yielding an edible fruit. It is found in the district of Tippera, to the eastward of Calcutta, and also in China, where it is cultivated for its agreeable fruit, according to information obtained by Dr. Roxburgh from Chinese gardeners. It is remarkable that it should there be called Lutqua, as it is called Lutco by the Hindus on the eastern frontier of Bengal.

RAMBERVILLER. [VOSGES.]

RAMBOOTAN, a fruit of the Malayan archipelago, belonging to the same genus (Nephelium, of the natural family of Sapindaceæ) as the Chinese fruits Litchee and Longan. The fruit is about the size of a pigeon's egg, something like that of the Arbutus, but larger, and of a brighter red. It has a skinny red coat covered with soft spines, whence is derived its Malay name from *rambut*, 'hair.' Within the covering is enclosed a small quantity of semi-transparent rich subacid pulp, which forms the edible part of the fruit, and covers a large kernel. Mr. Marsden describes the flavour of this fruit as rich and of a pleasant acid, but Mr. Crawford states that it is not much esteemed. It has been cultivated in this country in a rich light loam in hothouses.

RAMBOUILLET. [SEINE ET OISE.]

RAMILLIES, or RAMELIES, a small village, with about 600 inhabitants, in the province of South Brabant, 13 miles north of Namur and 26 south-east of Brussels, in the present kingdom of Belgium. A victory was obtained in its vicinity, on the 23rd of May, 1706, by the allied army under the Duke of Marlborough and the Dutch field-marshal Van Ouwerkerk, over the French and Bavarians commanded by Marshal Villeroi and the Elector of Bavaria. This battle is considered as the most complete and successful exemplification of the military talents of Marlborough. The numbers were about 60,000 men on each side, but the French generals were no match for Marlborough: and the day ended in a complete victory on the part of the allies, who lost only 4000 men, while the loss of the French was 15,000. The immediate evacuation of Flanders by the French was the result of this battle.

RAMIRO II., son of Ordoño II, succeeded to the throne of Asturias and Leon by the abdication of his elder brother Alfonso IV., surnamed 'el Monge' (the monk), who, in 930, renounced the vanities of the world, and retired into the monastery of Sahagun. Ramiro rendered himself illustrious by his wars with the Mohammedans, from whom he wrested many considerable districts and towns, thereby extending the limits of the small kingdom founded by Pelayo. [PELAYO.] Soon after his accession to the throne (932), Ramiro, profiting by the internal troubles which at that time agitated the Mohammedan empire, made a successful irruption into the states of Abd-er-rahmân, the reigning khalif, destroying Madrid, Talavera, and other towns; and when Al-mudaffer, the khalif's uncle, arrived at the head of considerable forces to revenge the outrage, he defeated him with dreadful carnage on the banks of the Duero, not far from the town of Osma. In 938 Ramiro turned his victorious arms to another quarter; he invaded Aragon, or *Thagher* (as that province was then called by the Arabs), and laid siege to its capital, Saragossa, which he would have reduced if the governor had not hastened to pay him homage and acknowledge himself a feudatory of his crown; though these advantages seem to have been counterbalanced by the victory gained by the Mohammedans over his troops in 938, near a village called Sotuscobas. Ramiro was again victorious in a battle fought under the walls of Ramora, in which the Moslems, according to their own authorities, lost upwards of 40,000 men, and Abd-er-rahmân himself was well nigh taken prisoner. [MOORS.] Ramiro, like most of his predecessors, had often to contend with internal enemies. Scarcely had he ascended the throne when his brother Alfonso, growing weary of monastic life, forsook his cell, and with a considerable force hastened to Leon to reclaim his throne. He was there invested by Ramiro, who compelled him to surrender, and again consigned him to his monastery, where he was soon after deprived of his eyes, a species of punishment much in use among the Visigoths of Spain. The dependent count of Castile, Ferran-Gonzalez, and one Diego Nuñez, a count also in the same province, next revolted against Ramiro, but he marched against them, seized their persons, and confined them to a dungeon; though he soon after pardoned them and even married his eldest son Ordoño to Urraca, daughter of Ferran. Ramiro died on the 5th of January, 950, after a glorious reign of nearly twenty years. Some time before his death he abdicated in favour of his son Ordoño, and, assuming the penitential garb, passed the remainder of his days in religious retirement.

RAMISERAM. [CEYLON.]

RAMLER, C. W. [GERMANY, vol. xi., p. 196.]

RAMPHA'STIDÆ (*Toucans*), a family of scansorial birds.

Belon, at the end of the twenty-eighth chapter of his third book 'De la Nature des Oyseaux vivants le long des rivières, ayants le pied plat, nommez en Latin *Palmipedes aves*' (A.D. 1555), gives a wood-cut of the bill of a Toucan, which, from the black patch at the end of it, was probably that of *Ramphastos Toco*. He describes the bill as belonging to a bird of the *terres neufues*, which possesses that organ half a foot long, large as a child's arm, pointed and black at the tip, white elsewhere, and notched some little on the edges, hollow within, and so finely delicate that it is transparent and thin as parchment. Its beauty, he observes, has caused it to be kept in the cabinets of the curious. He further says that he has not seen the bird, but that he suspects that it is *de pied plat*, and therefore he has placed it with the River Birds.

In the 'Portraits d'Oyseaux' also, the cut of this bill is placed at the end of 'Le Second Ordre des Oyseaux au pied plat.' Above it appears the following description:—

'Bec d'un Oyseau aquatique apporté des terres neufues.'

"Si quelqu'un avoit fait un corps d'oyseau à ce bec sans avoir grosseur suffisante, qu'on le juge fait à discretion, car nous l'avons mieux aymé laisser ainsi, que luy en feindre un.'

Below the cut is the following quatrain,—

[illegible]

The birds themselves do not seem to have found their way to England a century after the date of Belon's works; for, in the Museum Tradescantianum, the standard collection of the time, and which, from the list of contributors, appears to have been the great receptacle for all curiosities, we read, under the division (No. 2) of *Beaks or Heads*,—'Aracari of Brazil, his beak four inches long, almost two thick, like a Turk's sword' (A.D. 1656). But if the bird itself had not been brought forward, it is probable that Tradescant knew its nature, from the description above given. Petiver (tab. xiv., f. 13) gives a figure of the bird complete, and though it bears all the marks of the imperfect state of the arts at that time, as far as engravings of subjects of natural history are concerned, it is substantially correct, and the arrangement of the toes right. The description is, 'Toucan Surinamensis niger, ex albo, flavo, rubroque mixta,' taken from a Dutch painting, in Mr Clark's collection: this does not exactly agree with any authors I have yet read.' Willughby (tab. xx.) gives a figure of a Toucan (*Ramphastos Toco*, probably) under the name of 'the Brazilian Pie of Aldrovandus, the Toucan of Marcgrave and others, the Xochitenacatl of the Mexicans: Nieremb.' The figure is incorrect about the feet, to which three anterior toes are given, though Willughby, who cites Thevetius, Faber, Dal Pozzo, Lerius, Oviedo, and John de Laet, was evidently aware of the true organization, viz. two toes before and two behind.

Brisson placed the form in his thirteenth order, consisting of those birds which have four toes, two before and two behind.

Linnæus arranged the Toucans (*Ramphastos*) at the head of the second division (*pedibus scansoriis*) of his second order, *Picæ*.

Latham also assigned to them the same situation.

Lacépède places *Ramphastos* at the head of the second order (*Bec dentelé*) of his *Grimpeurs*, or climbers.

Duméril arranged the form at the head of the *Levirostres*, or *Cénoramphes*, the second family of his third order, *Grimpeurs*.

The *Scansores* form the first order in the method of Illiger, and *Ramphastos* and *Pteroglossus* appear at the head of the second family, *Serrati*.

In Cuvier's system the Toucans are arranged in his third order, *Grimpeurs*, between the *Anis* [CROTOPHAGA] and the Parrots [PSITTACIDÆ].

The *Zygodactyli* are the first tribe of M. Vieillot's second order, *Sylvicolæ*, and the Toucans are placed in the fourth family, *Pteroglosses*, between the Jacamars and Barbets.

M. Temminck arranges the form in the first family of his fifth order, *Zygodactyles*.

Mr Vigors (*Linn. Trans.*, vol. xiv.) opens his section on the *Scansores* with a remark on the deviation which had been observed in the *Bucerotidæ* (arranged by him among the *Conirostres*) from the more perfect formation of the foot, as preparing us for the still more considerable deviation that takes place in the same particular among the *Scansorial Birds*. 'Besides the approach which we have just noticed in the *Bucerotidæ* [HORNBILLS] to the imperfect form of the scansorial foot, we may perceive that the large and disproportionate bill of that family is carried on to the *Ramphastidæ*, the first family of the *Scansores* that meets our attention. There is seldom perhaps a surer guide to relations of affinity and analogy than common observation; and a trivial or provincial name often anticipates the more correct and scientific views of the naturalist. In seeking for the immediate point of junction between the two tribes now before us, we are in this manner directed at once to the object of our search; a scansorial genus, belonging to the family of *Ramphastidæ*, the *Scythrops* of Dr. Latham being designated, as may be seen in the collection belonging to the Linnean Society, by the denomination of *Psittaceous Hornbill*.' [SCYTHROPS.] The family of *Ramphastidæ* then, according to Mr. Vigors, consists of the genera *Ramphastos*, Linn., and *Pteroglossus*, Ill., which fill up the same station in the New World that *Buceros* maintains in the Old. To these genera he adds *Scythrops*, as equally assimilated to both groups, and thus supplying their place in Australasia. *Scythrops*, in the opinion of Mr. Vigors, unites the *Ramphastidæ* with the larger and more prominent billed *Cuculidæ*, which meet it at the other extremity of the tribe. The connection of *Ramphastos* with the *Psittacidæ* is, he observes, not so evident. [PSITTACIDÆ, vol. xix., p. 65.]

The *Grandirostres* form the fifth family of the *Grimpeurs*, the third order in the system of M. Latreille: and embrace the genera *Toucan* and *Aracari*, which are placed between the *Proglosses* (Wryneck, Woodpecker, &c.) and the *Gallibirostres* (*Musophaga, Touraco*).

The Toucans appear as the fifteenth family of the Normal Birds of M. de Blainville, and are placed between *Buceros* and *Picus*.

In M. Lesson's 'Projet' the *Ramphastidæ* succeed the *Picidæ*, and are the last family of the first tribe of his *Insessores* or *Grimpeurs* (*Heterodactyles*).

Mr. Swainson (*Classification of Birds*) states that the fourth family of the *Scansores*, or *Climbing Birds*, is represented by the *Toucans*, whose enormous bills give to these birds a most singular and uncouth appearance. He remarks that their feet are formed, like those of the parrots, more for grasping than climbing, and that they do not appear to possess the latter faculty; but as they always live among trees, and proceed by hopping from branch to branch, their grasping feet are peculiarly adapted to such habits. He adds that the intervals between the toucans and the parrots is not perhaps so great as between the latter and the woodpeckers; but that still it is sufficiently wide to make us believe that one if not two of the intervening types are wanting. The genera of the *Ramphastidæ*, according to Mr. Swainson, are *Ramphastos*, *Pteroglossus*, *Aulacorhynchus*,* and *Scythrops*.

Mr. G. R. Gray (*List of the Genera of Birds*) makes the *Ramphastidæ* the first family of the *Scansores*, with the following genera:—

Rhamphastos, Linn. (*Pica*, Gesn., *Tucano*, Briss.).

Pteroglossus, Ill. (*Ramphastos*, Linn.).

Selenidera, Gould (*Ramphastos*, Linn.; *Pteroglossus*, Wagl.).

Aulacoramphus (*Ramphastos*, Linn.; *Pteroglossus*, Sw.; *Aulacorhynchus*, Gould).

Scythrops, Lath.

Mr. Gould, in his beautiful monograph of the *Ramphastidæ*, divides them into two great sections:—

1. Caudâ breviore, quadratâ; rostro maximo. *Nigri, gutture caudæque tegminibus discoloribus.* RAMPHASTOS. (The *Toucans*.)

Of these Mr. Gould records eleven species, arranged in four subdivisions, according to the distribution of their colouring.

2. Caudâ longiore, graduatâ; rostro majore. *Viridescentes; capite, gastræo, tegminibusque caudæ superioribus in plurimis discoloribus.* PTEROGLOSSUS. (The *Araçaris*.)

Of these Mr. Gould records twenty-two species, arranged in twelve subsections, also according to the distribution of their colouring.

Geographical Distribution, Habits, &c.—The *Toucans* and *Araçaris* appear to be restricted in their geographical range to tropical America, and there they live retired in the deep forests, mostly in small companies. Their flight is straight but laborious, and not graceful; while their movements, as they glide rather than hop from branch to branch, are elegant.

Mr. Broderip gives the following account of the habits of a Toucan (*Ramphastos erythrorhynchus*) in captivity. Mr. Swainson, who had seen the Toucans in their native forests, had previously informed Mr. Broderip that he had frequently observed them perched on the tops of lofty trees, where they remained as if watching. This circumstance, joined to others connected with the remains of food found in the stomachs of such as were dissected, induced Mr. Swainson to suspect that these birds were partly carnivorous, feeding upon eggs and young birds, as well as fruits and berries; and that while perched upon those high trees, the Toucans were in fact busily employed in watching the departure of the parent-birds from their nests. Mr. Swainson could never catch the Toucans in the fact, nor did anything appear in his dissections to determine with certainty on what they fed. Mr. Such informed Mr. Broderip that he had seen these birds in Brazil feed on the Toucan-berry, that he had frequently observed them engaged in quarrels with the monkeys, and that he was certain that the Toucans fed also on eggs, nestlings, &c.

* [illegible]

On the 23rd of November, 1824, the late lamented Mr. Vigors had spoken at the Zoological Club of a living Toucan, which was then exhibited in St. Martin's Lane. Mr. Vigors stated that the bird had been fed on a vegetable diet; but that the proprietor had told him that on the occasion of a young Canary bird having escaped and gone near to the Toucan, the latter appeared more than usually excited, that thereupon the barrier between them was removed, and that the Toucan instantly seized and devoured the Canary bird. On the next day Mr. Broderip went to the place where the Toucan was exhibited, and thus describes what he saw:—

'After looking at the bird which was the object of my visit, and which was apparently in the highest state of health, I asked the proprietor to bring up a little bird, that I might see how the Toucan would be affected by its appearance. He soon returned, bringing with him a goldfinch, a last year's bird. The instant he introduced his hand with the goldfinch into the cage of the Toucan, the latter, which was on a perch, snatched it with his bill. The poor little bird had only time to utter a short weak cry; for within a second it was dead, killed by compression on the sternum and abdomen, and that so powerful that the bowels were protruded after a very few squeezes of the Toucan's bill. As soon as the goldfinch was dead, the Toucan hopped with it, still in his bill, to another perch, and placing it with his bill between his right foot and the perch, began to strip off the feathers with his bill. When he had plucked away most of them, he broke the bones of the wings and legs (still holding the little bird in the same position) with his bill, taking the limbs therein, and giving at the same time a strong lateral wrench. He continued this work with great dexterity till he had almost reduced the bird to a shapeless mass; and ever and anon he would take his prey from the perch in his bill, and hop from perch to perch, making at the same time a peculiar hollow clattering noise; at which times I observed that his bill and wings were affected with a vibratory or shivering motion, though the latter were not expanded. He would then return the bird to the perch with his bill, and set his foot on it. He first ate the viscera, and continued pulling off and swallowing piece after piece, till the head, neck, and part of the back and sternum, with their soft parts, were alone left: these, after a little more wrenching, while they were held on the perch, and mastication, as it were, while they were held in the bill, he at last swallowed, not even leaving the beak or legs of his prey. The last part gave him the most trouble; but it was clear that he felt great enjoyment; for whenever he raised his prey from the perch he appeared to exult, now masticating the morsel with his toothed bill and applying his tongue to it, now attempting to gorge it, and now making the peculiar clattering noise accompanied by the shivering motion above mentioned. The whole operation from the time of seizing his prey to that of devouring the last morsel lasted about a quarter of an hour. He then cleaned his bill from the feathers by rubbing it against the perches and bars of his cage. While on this part of the subject it may be as well to mention another fact, which appears to me not unworthy of notice. I have more than once seen him return his food some time after he had taken it to his crop, and, after masticating the morsel for awhile in his bill, again swallow it; the whole operation, particularly the return of the food to the bill, bearing a strong resemblance to the analogous action in ruminating animals. The food on which I saw him so employed was a piece of beef, which had evidently been macerated some time in the crop. While masticating it, he made the same hollow clattering noise as he made over the remains of the goldfinch. Previous to this operation he had examined his feeding-trough, in which there was nothing but bread, which I saw him take up and reject; and it appeared to me that he was thus reduced from necessity to the above mode of solacing his palate with animal food. His food consists of bread, boiled vegetables, eggs, and flesh, to which a little bird is now added about every second or third day. He shows a decided preference for animal food, picking out all morsels of that description, and not resorting to the vegetable diet till all the former is exhausted.

'It is said that the nerves are very much expanded within the internal surface of the bill in these birds; and independently of the sensual enjoyment which the Toucan above mentioned appeared to derive from palating his prey, I have observed him frequently scratching his bill with his foot, which may be considered as furnishing additional evidence of the sensibility of this organ. While taking his prey he never used his foot for the purpose of conveying it either to his bill or elsewhere. The bill was the sole vehicle and the organ actively employed; the foot merely confined the prey on the perch.

'But there is yet another of the peculiarities of this bird which cannot be passed over in silence. When he settles himself to roost, he sits a short time with his tail retroverted, so as to make an acute angle with the line of his back; he then turns his bill over his right shoulder, nestling it in the soft plumage of the back (on which last the under mandible rests), till the bill is so entirely covered that no trace of it is visible. When disturbed, he did not drop his tail, but almost immediately returned his bill to the comfortable nidus from which on being disturbed he had withdrawn it. He broke a short time ago some of his tail-feathers, and the proprietor informed me that before that accident the bird when at roost retroverted his tail so entirely that the upper surface of the tail-feathers lay over and came in contact with the plumage of the back; so that the bird had the appearance of a ball of feathers, to which indeed when I saw him he bore a very considerable resemblance. The proprietor informs me that he always roosts in the same way.' (*Zool. Journ.*, vol. i.)

In a subsequent volume (ii.) Mr. Vigors gives the following interesting account of a Toucan, *Ramphastos Ariel* (Vig.), which he kept in a state of domestication for many years:—

'With respect to the manners of my bird, I can add but little to the very accurate and interesting account of those of a species nearly allied to it, which has appeared in a preceding number of this journal.* I have not allowed it to be indulged in that disposition to animal food which so strikingly belongs to this family. I find in fact that it thrives sufficiently well upon a vegetable diet; and I fear that if it should once be allowed any other, it would be difficult to restrain its inclination for it within moderate limits. Eggs are the only animal food with which it has been supplied since it came into my possession. Of these it is particularly fond, and they are generally mixed up in his ordinary food, which consists of bread, rice, potatoes, German paste, and similar substances. He delights in fruits of all kinds. During the period when these were fresh, he fed almost exclusively on them; and even in the present winter months he exhibits great gratification in being offered pieces of apples, oranges, or preserved fruits of any description. These he generally holds for a short time at the extremity of his bill, touching them with apparent delight with his slender and feathered tongue; and then conveying them by a sudden upward jerk to his throat, where they are caught and instantly swallowed. His natural propensity to preying upon animals, although not indulged, is still strongly conspicuous. When another bird approaches his cage, or even a skin or preserved specimen is presented to him, he exhibits considerable excitement. He raises himself up, erects his feathers, and utters that "hollow clattering sound" noticed by Mr. Broderip, which seems to be the usual expression of delight in these birds; the irides of his eyes at the same time expand, and he seems ready to dart upon his prey, if the bars of his cage permitted his approach. On one occasion, when a small bird was placed by chance over his cage at night, he showed great restlessness, as if aware of the neighbourhood of the bird; and he would not be composed until the cause of his anxiety was discovered and removed.

'When in his cage, he is peculiarly gentle and tractable, suffers himself to be played with, and feeds from the hand. Out of his cage, he is wild and timid. In general he is active and lively; and, contrary to what might be expected, from the apparent disproportion of the bill and the seemingly clumsy shape of the birds of this genus, as they are usually set up or represented in figures, his appearance is not only graceful, but his movements, as he glides from perch to perch, are light and sylph-like; so much so as to have suggested to an intelligent friend who witnessed them the specific name which I have ventured to assign him. He keeps himself in beautiful plumage, his lighter colours being strikingly vivid, and the deep black of his upper body in particular being always bright and glossy. For this fine condition he seems to be much indebted to his fondness for bathing. Every day he immerses himself in cold water with apparent pleasure, even in this severe weather; and

* Mr. Broderip's account, above given.

in no respect indeed does he appear to suffer by the transition from his own warm climate to our uncongenial atmosphere.

'Besides the "hollow clattering noise," as my friend Mr. Broderip so expressively terms the usual sounds of these birds, he utters at times a hoarse and somewhat discordant cry when he happens to be hungry, and to see his food about to be presented to him. On such occasions he stands erect, raising his head in the air, and half opening his bill as he emits this cry. These are the only sounds I have heard him utter; and in neither can I say that I have detected any similarity, or even approach, to the word Toucan, as has sometimes been asserted, and from whence the trivial name of the genus has been supposed to originate. Neither have I been able to verify another observation which has been advanced respecting these birds, that the bill is compressible between the fingers in the living bird. The bill, notwithstanding the lightness of its substance, is firm, and capable of grasping an object with much strength. The mode in which Mr. Broderip describes his Toucan as having broken the limbs of the bird which he was about to devour, by "a strong lateral wrench," sufficiently shows that the bill is not deficient in power. Indeed I generally observe that my bird takes what is offered him rather by the sides than by the point of his bill; and I suspect that much of the powers of that member are centred in this lateral motion. The serration of the edges also may be supposed to tend to these peculiar powers. The manner in which he composes himself to rest is represented in the accompanying plates. Since the cold weather has commenced, he has been brought into a room with a fire, and the unusual light seems to have interfered with his general habits; he does not go to rest as early or as regularly as was his custom; and he sometimes even feeds at a late hour. During the warmer months however, when he was more free from interruption, his habits were singularly regular. As the dusk of the evening approached, he finished his last meal for the day; took a few turns, as if for exercise after his meal, round the perches of his cage; and then settled on the highest perch, disposing himself, almost at the moment he alighted on it, in the posture represented, his head drawn in between his shoulders, and his tail turned vertically over his back.

Toucan at roost; first stage.

'In this posture he generally remained about two hours, in a state between sleeping and waking, his eyes for the most part closed, but opening on the slightest interruption. At such times he would allow himself to be handled, and would even take any favourite food that was offered him without altering his posture further than by a gentle turn of the head. He would also suffer his tail to be replaced by the hand in its natural downward posture, and would then immediately return it again to its vertical position. In these movements the tail seemed to turn as if on a hinge that was operated upon by a spring. At the end of about two hours he began gradually to turn his bill over his right shoulder, and to nestle it among the feathers of his back, sometimes concealing it completely within the plumage, at other times having a slight portion of the culmen exposed. At the same time he drooped the feathers of his wings and those of the thigh-coverts, so as to encompass the legs and feet; and thus nearly assuming the appearance of an oval ball of feathers, he secured himself against all exposure to cold.'

Toucan at roost; second stage.

All are now agreed that in a state of nature the *Ramphastidæ* are omnivorous. Mr. Swainson (*Classification of Birds*) says, 'The apparent disproportion of the bill is one of the innumerable instances of that beautiful adaptation of structure to use which the book of nature everywhere reveals. The food of these birds principally consists of the eggs and young of others, to discover which nature has given them the most exquisite powers of smell;' and he notices the size of the bill as ancillary to this development.

Mr. Gould, who alludes to the papers of Mr. Broderip and of Mr. Vigors, states that in their choice of food the Ramphastidæ are perfectly omnivorous; and although their elastic bill and delicately feathered tongue would lead us to conclude that fruits constituted the greatest proportion of their diet, we have abundant testimony that they as readily devour flesh, fish, eggs, and small birds, to which, in all probability, are added the smaller kinds of reptiles, caterpillars, and the larvæ of insects in general.

The incubation of most if not all of this family takes place in the holes of trees, a habit that was very early known. We find Willughby, after quoting Faber for proof that in the structure of their feet, &c., the toucans resemble the woodpeckers, 'to the genus whereof the toucan, as Faber in this place proves, doth undoubtedly belong,' continuing thus: 'for it not only hath a like situation of toes, but also in like manner hews holes in trees to build its nest, as Fryer Peter Alvaysa, and other Indians and Spaniards, who had long lived in America, told Faber for a certain truth; and Oviedus, in the forty-third chapter of his summary of the history of the West Indies, published in Italian, writes, adding that he thinks there is no bird secures her young ones better from the monkeys, which are very noisome to the young of most birds. For when she perceives the approach of those enemies, she so settles herself in her nest as to put her bill out at the hole, and gives the monkeys such a welcome therewith that they presently pack away, and glad they escape so. From this quality of boring the trees, this bird is by the Spaniards called *carpintero*, and by the Brazilians *tacataca*, in imitation, I suppose, of the sound it makes.' The feathered structure of the tongue is also there noticed.

Mr. Gould remarks that the true toucans, unlike many of the araçaris, offer no sexual difference in the colour of the plumage; but the females are rather less than the males in all their proportions. He adds that the young of both genera assume at a very early age the adult colouring; but that their large bills, as might be expected, are not fully developed for a considerable period.

The colours of the bill, which are generally very vivid during life, become, in many instances, greatly changed and deteriorated by death: this should be borne in mind by those who describe species from dead specimens, especially if they have been a long time preserved.

Before we proceed to the description of one or two of the species of this most interesting family, it will be necessary to lay before the reader a summary of the anatomy of this form, as it has been demonstrated by Professor Owen, in Mr. Gould's *Monograph*.

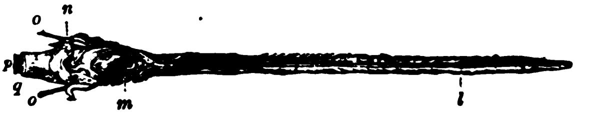
Organization.

Digestive Organs.—Professor Owen remarks that the organs of digestion in the toucan present a general simplicity of structure, which accords with its geographical position and power of assimilating both animal and vegetable food, so abundantly provided by nature in a tropical climate. The size of the œsophagus and general width of the intestinal canal correspond to the magnitude of the beak. There is no lateral dilatation of the crop, nor is the gizzard so encroached upon by its muscular parietes as to render such a reservoir for the alimentary substances necessary. The intestinal canal is equally devoid of lateral pouches, or *cæca;* the gastric glands are of a simple form, and are disposed for the extent of an inch around the termination of the œsophagus. The communication of the gizzard with the proventriculus is free, readily permitting regurgitation to take place; and here Professor Owen refers to the record of that act in the papers of Mr. Broderip and Mr. Vigors, adding that as the substances so regurgitated were, after undergoing a second mastication, again swallowed, the act may be compared to the rumination of herbivorous quadrupeds.

In the museum of the Royal College of Surgeons, No. 524 D, prepared by the professor, shows the proventriculus and gizzard of *Ramphastos Ariel*, Vig. It will be seen that the lining membrane at the termination of the œsophagus is thrown into narrow but distinct longitudinal folds; as it passes into the proventriculus it becomes finely reticulate, the orifices of the gastric glands being situate in the interstices of the meshes. These glands are simple cylindrical follicles, forming a complete zone at the end of the gullet, and not separated from that tube by any constriction. The proventriculus communicates with the gizzard by an equally wide aperture. The muscular coat of the gizzard does not exceed half a line in thickness the lateral tendons are small, but very distinct. The lining membrane is of a horny texture, and was stained of a deep yellow colour. The pyloric orifice is remarkably contrasted in its diminutive size with the ample entrance to the gizzard; a structure which facilitates the regurgitation of the alimentary substances. The description then goes on to state that as the regurgitated morsels have been observed to undergo a second mastication, the digestive processes exhibit in this bird the analogy to the ruminants above noticed, and that as the thin parietes of the gizzard of this omnivorous bird are sometimes unequal to the comminution of the food, the utility of the extraordinary developed beak becomes apparent, which thus compensates by additional mastication for the absence of the grinding structure so peculiar to the stomachs of the true vegetable-feeders. (*Cat. Mus. Coll. Chir.*) Professor Owen states that the intestinal canal does not exceed the length of the body including the bill, and that the general structure of the digestive apparatus of the hornbill agrees with that of the toucan. The liver of the latter is composed of two lobes of unequal size, joined by a small band, and the margins of the lobes are more rounded than usual. There is no gall-bladder, and Mr. Owen remarks that in this deficiency the toucan manifests an affinity to the *Picidæ* and *Psittacidæ*, among the *Scansores;* while the hornbill, on the contrary, resembles the *Corvidæ* in the large development of its biliary receptacle. A small hepatic duct enters the duodenum near its commencement; and a second duct, about two lines in diameter, passes to a more distant part of the intestine,' where it terminates close to the insertion of the two pancreatic ducts.

The same anatomist states that the length of the tongue, one of the most remarkable among birds, in a full grown *Rhamphastos Toco* was six inches. The posterior ridge, or backward-projecting process, was broad and finely notched, and situated about four lines from the glottis. Anterior to this process, Mr. Owen describes the tongue as being soft and minutely papillose for the extent of four lines, and here he thinks most probably the sense of taste resides: the rest of the organ consists of a transparent horny lamina, flattened horizontally, and supported by the anterior process of the os hyoides, which forms a ridge along the middle of its inferior surface. At about four inches from the extremity of the horny lamina the margins become obliquely notched, and these notches, becoming deeper and closer together towards the extremity, occasion the bristled appearance on each side of the tongue: these bristles were applied to the food in the cases of the captive toucans above recorded. The cornua of the os hyoides are 1½ inches in length.

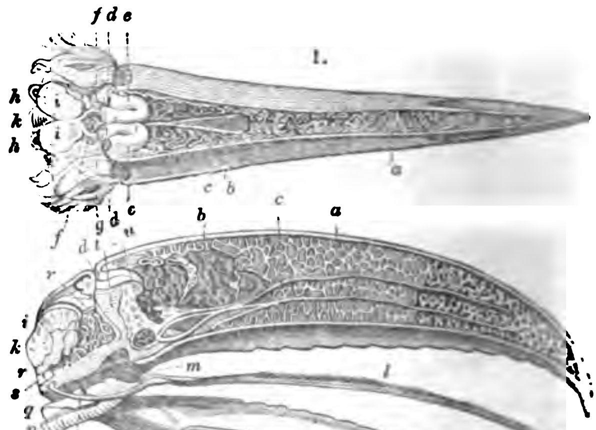
No. 1479 B. (*Mus. Coll. Chir., Physiol. Series*) is the preparation of the tongue of a toucan, showing the flat sheath of horn and the series of short processes directed forwards on each side like the barbs of a feather. The upper larynx, wide fauces, and commencement of the trachea are also here preserved. The base of the tongue is soft, and covered with fine papillæ; it forms posteriorly a denticulated ridge, which is directed backwards, and may serve to protect the laryngeal aperture like an epiglottis. (*Cat. Mus. Coll. Chir.*, vol. iii.)



Upper surface of Tongue of Toucan. (Owen.)

l, The fringed or feathered portion; *m*, orifice of larynx; *n*, orifice of pharynx; *o*, cornua of the os hyoides; *p*, trachea or windpipe; *q*, gullet.

Mr. Owen observes that the osseous portions of the mandibles of the Toucan are disposed in a manner adapted to combine with the great bulk of those parts a due degree of strength and remarkable lightness, and the bony structure is consequently of a most beautiful and delicate kind. 'The external parietes,' continues Mr. Owen, 'are extremely thin, especially in the upper beak: they are elastic and yield in a slight degree to moderate pressure, but present considerable resistance if a force is applied for the purpose of crush-



1. Section of the cranium and upper mandible of Ramphastos Toco. *a*, The cancellated structure of the beak; *b*, the cavity at the base; *c*, branches of the fifth pair of nerves; *d*, *d*, external orifices of the nostrils; *e*, osseous parietes of the nasal passages; *f*, osseous tubes protecting the olfactory nerves; *g*, pituitary membrane exposed, and branches of the olfactory nerves radiating on it; *h*, superior semicircular canals of the internal ear; *i*, *i*, hemispheres of the cerebrum; *k*, cerebellum. (Owen.)

2. Vertical longitudinal section of the head. The same letters indicate the same parts as in the previous figure. *l*, The tongue; *m*, glottis; *n*, internal aperture of the nostrils; *o*, os hyoides; *p*, trachea; *q*, œsophagus; *r*, beginning of the spinal chord; *s*, articulating surface of occipital bone; *t*, nasal septum or partition; *u*, air-cell anterior to the orbit, from which the air passes into the mandible; *v*, cancellated structure of the lower jaw. (Owen.)

ing the beak. At the points of the mandibles the outer walls are nearly a line in thickness; at other parts in the upper beak they are much thinner, varying from 1-40th to 1-20th part of an inch, and in the lower beak are from 1-20th to 1-30th part of an inch in thickness. On making a longitudinal section of the upper mandible, its base is seen to include a conical cavity, about two inches in length and one inch in diameter, with the apex directed forwards. The walls of this cone consist of a most beautiful osseous net-work, intercepting irregular angular spaces, varying in diameter from half a line to two lines. From the parietes of this cone a network of bony fibres is continued to the outward parietes of the mandible, the fibres which immediately support the latter being almost invariably implanted at right angles to the part in which they are inserted. The whole of the mandible anterior to the cone is occupied with a similar network, the meshes of which are largest in the centre of the beak, in consequence of the union which takes place between different small fibres as they pass from the circumference inwards. It is remarkable that the principle of the cylinder is introduced into this elaborate structure: the smallest of the supporting pillars of the mandibles are seen to be hollow or tubular, when examined with the microscope. The structure is the same in the lower mandible, but the fibres composing the net-work are in general stronger than those of the upper mandible.'

Nervous System and Senses.—Mr. Owen states that the medullary membrane lining these cavities appears to have but a small degree of vascularity. Processes of the membrane, accompanying vessels and nerves, decussate the conical cavity at the base of the beak. The principal nerves are two branches of the fifth pair, which enter at the lower part of the conical cavity, and diverge and ascend as they pass forward to the end of the bill, giving off branches, which are distributed to the horny covering, and supply it with sensibility. 'The air,' says Mr. Owen, 'is admitted to the interior of the upper mandible from a cavity situated anterior to the orbit, which communicates at its posterior part with the air-cell continued into the orbit, and, at its anterior part, with the maxillary cavity. The nasal cavity is closed at every part, except at its external and internal apertures, by the pituitary membrane, and has no communication with the interior of the mandible.'

Smell.—'The organ of smell is confined to the base of the upper jaw. The canal, which is traversed by the air and odorous particles in inspiration, forms a sigmoid curve in the vertical direction. The external orifice is on precisely the same perpendicular line as the internal one. It is situated at the posterior surface of the upper mandible, where it is raised above the level of the cranium; the orifice is consequently directed backwards, secure from all injury that might happen to it in the act of penetrating dense or interwoven foliage. The olfactory canal is at first of almost a cylindrical form, and about two lines in diameter. It passes forwards for about half an inch, receiving from the mesial aspect the projection of the first spongy bone; it then bends downwards and backwards, and is dilated to admit the projections of the two other spongy bones: from this point it descends vertically to the palate, at first contracted, and afterwards dilating to form the internal or posterior orifice. The first or outermost spongy bone is almost horizontal, and has its convexity outwards. The second is nearly vertically placed, with its convexity directed backwards: it terminates in a narrow point below. The third or superior spongy bone makes a small projection towards the mesial plane about the size of a pea. These spongy bones are formed by inward projections of the inner and posterior osseous parietes of the nasal passage: they are cellular, and air is continued into them from the cranial diploë; but the parietes of the nasal passage are entire and smooth, and lined by a delicate pituitary membrane. The inner table of the skull is continuous with the parietes of the nasal cavity, by means of the bony canal which accompanies and protects the olfactory nerves, and which represents, as it were, a single foramen of the cribriform plate of the mammalia. The communication of the cavity of the cranium with that of the nose is thus similarly formed, and is only obstructed in the recent state by the pituitary membrane, on the posterior *cul-de-sac* of which the olfactory nerve distributes its branches in a radiated manner. These branches were confined, as Scarpa has observed in other birds, to the pituitary membrane covering the septum narium and the superior spongy bone.'

Hearing.—'The external orifice of the meatus auditorius is situated about half an inch behind the lower boundary of the orbit. The membrana tympani closes it so obliquely that its plane is directed almost backwards; its anterior edge is consequently about three lines from the external orifice, while its posterior margin is at least six lines from the same point. It is convex outwardly, as in birds generally. The apparatus of the internal ear is easily exposed, the semicircular canals being lodged in a delicate reticulation of the diploë of the cranium. These parts, with the ossiculum of communication and the cochlea, do not present any deviations from the ordinary structure worthy of notice.'

Sight.—The sense of sight in the *Ramphastidæ* appears to be sufficiently well developed, but requires no special observation.

Respiratory and Circulating System.—Mr. Owen found the trachea narrow and simple in its structure, the rings somewhat flattened, and decreasing in diameter towards the inferior extremity, from which a single pair of muscles passes off to the sternum. The length of the lower fourth of the tube, and the state of tension in the bronchia are regulated by a pair of small muscles, which, arising from the sides of the tracheal cartilages, are inserted into the bone of divarication at the extremity of the trachea: this part of the tube is subjected to variations in length, as is indicated by the tortuous character of the recurrent nerves attached to the sides of the trachea in this part. The lungs, small in proportion, are of the usual form and structure, and the abdominal air-cells are also small. The heart is more oblong than it is in birds generally; its apex, as it were, truncate; and its length one inch.

Urinary and Genital System.—The kidneys, composed of three lobes, of which the middle one is smallest, are an inch and a half in length, with a surface convoluted, though in a less marked degree than it is in reptiles. Between the anterior extremities of these glands Mr. Owen found, in a female *Ramphastos Ariel*, the ovary of a triangular shape, and apparently healthy. The ova were like minute granules, and disposed in a convoluted manner. The supra-renal glands were imbedded in the posterior part of the ovary. The oviduct, of the size of a crow-quill, commenced by the usual fimbriated and wide aperture, was slightly tortuous at the commencement, and then continued straight to the cloaca.

Osseous and Muscular Systems.—Certain parts of this system bear upon peculiar functions performed by the Toucans, and are thus described by Professor Owen:—'The pectoral muscles, as in the *Psittacidæ*, are but feebly developed, and the keel of the sternum is of moderate size, not projecting more than half an inch from the plane of the bone. The sternum has four notches at its posterior margin. The clavicles, or lateral halves of the furcula, are here, as in the *Psittacidæ* and *Struthionidæ*, separate; they are an inch in length, slender, pointed at their lower ends, and joined to each other and to the sternum by a ligament only.'

'The peculiar motions of the tail called for a particular examination of that part. It is difficult to state the precise number of the caudal vertebræ, in consequence of the terminal ones being anchylosed, requiring for this purpose the examination of a young specimen at a period before the anchylosis takes place. In the skeleton of a Black-billed Toucan which I have examined, it would appear that three vertebræ are thus anchylosed, making the entire number of coccygeal vertebræ nine. The Woodpecker has also nine caudal vertebræ, and this seems to be the greatest number found in birds. The first six of these vertebræ in the Toucan are articulated by ball-and-socket joints, the ball and the socket being most distinct in the last two joints. That between the sixth and the anchylosed vertebræ is provided with a capsule and synovial fluid; the others have a yielding ligamentous mode of connection. The spinous processes of these vertebræ, both superior and inferior, are of moderate size, but smallest in the sixth, where the greatest degree of motion takes place. The transverse processes, on the contrary, are large and broad, so as almost wholly to prevent lateral motion. The first of the anchylosed vertebræ is broad and flat, and of a rounded form, supporting the two coccygeal glands: the last of these processes is compressed laterally, and of the ordinary ploughshare form. The caudal vertebræ can be inflected dorsad till their superior spines are brought into contact with the sacrum; in the opposite direction they can scarcely be bent beyond a straight line; and it is to this structure of the bones and joints that is to be attributed the capability in the Toucan of turning its tail upon its back (as represented in the 'Zoological Journal,' vol. ii., pl. xv.*), the muscles presenting comparatively few peculiarities, since the motion alluded to is remarkable rather for its extent than the vigour with which it is performed. The principal elevators of the tail are the sacro-coccygei superiores (sacro-sus-caudiens of Vicq d'Azyr). They arise from two longitudinal ridges on the inferior and convex part of the sacrum, and are inserted into the superior spines of the first six vertebræ by detached tendons terminating broadly in the anchylosed vertebræ. The principal antagonists of these muscles, the sacro-coccygei inferiores (sacro-sous-caudiens of Vicq d'Azyr), pass over the first five vertebræ, and terminate in the sixth and anchylosed vertebræ; their origins are wider apart than in the preceding pair of muscles, coming off from the margin of the sacro-sciatic notches. In the interval are situated small muscles passing from the transverse processes to the inferior spines of the first six vertebræ. From the limited nature of the lateral motions of the tail, the muscles appropriate to these movements are feeble, especially in comparison with those which are observed in the birds that spread their tail-feathers in flight, in order to regulate their course during that vigorous species of locomotion. These muscles are in number two on each side, arising from the posterior extremites of the ischia, and inserted into the expanded anchylosed vertebræ. From the disposition of these muscles it is obvious that after the proper elevators have raised the tail to a certain height, they also become dorsad of the centre of motion, combine their forces with the elevators, and by this addition of power terminate the act of throwing up the tail by a jerk. Mr. Vigors, in his observations on the living animal, observes, that "in these movements the tail seemed to turn as if on a hinge that was operated on by a spring."' (Owen, in Gould's *Ramphastidæ*.)

Foot of Toucan. *a*, seen from below.

We now proceed to give some examples of the *Toucans* and Araçaris.

Ramphastidæ.

Bill enormous, vascular within; the margins serrated. *Wings* short, rounded. *Feet* with two toes before and two behind. (Sw.)

Ramphastos.

Generic Character.—Bill smooth. *Nostrils* entirely concealed, and placed at the edge of the thickened frontlet of the bill. *Wings* short, rounded; the four outer quills graduated and abruptly pointed. *Tail* short, rounded. (Sw.)

Ramphastos Toco appears to be one of the largest species, being 27 inches in total length. The bill measures 7½ inches; the wings, 10; the tail, 7; and the tarsi are 2 inches in length. A beautiful figure of the bird, by Lear, is given in Mr. Gould's magnificent work. The range of the species is very wide, perhaps wider than that of any other, being distributed throughout the whole of the wooded districts from the River Plata to Guiana.

We select as an illustrative example, *Ramphastos Cuvieri*.

Description.—Beak brownish black on the sides, with a large basal belt and culminal line of greenish yellow, the basal belt being bounded behind by a narrow line of black, and before by a broader one of deep black, which is only apparent in certain lights; the top of the head and whole of the upper surface black, with the exception of the upper tail-coverts, which are bright orange yellow; cheeks, throat, and chest white, with a tinge of greenish yellow, terminated by a band of scarlet; under surface black; under tail-coverts scarlet. Total length 24 inches; bill 7½; wings 9; tail 6½; tarsi 2. (Gould.)

Mr. Gould states that this bird is very rare; his own specimen, which he says will be added to the museum of the Zoological Society of London, being the only one which he has ever seen, with the exception of another, of which he has some recollection, in the museum at Berlin. He adds that there is no example in the Paris collection.

Locality.—The densely-wooded districts on both sides of the Amazon.

* See page 289.

Ramphastos Cuvieri. (Gould.)

Pteroglossus.

Generic Character.—Bill smooth, less compressed. *Nostrils* vertical, naked, round, pierced on the upper surface of the bill, on the edge of the frontlet. *Wings* short, rounded. *Tail* lengthened, graduated. (Sw.)

Head of Aracari. (Gould.)

The following may be taken as examples of the genus.

Pteroglossus Humboldtii.

Description.—Bill large in proportion to the body; a band of black occupies the culmen from the base to the t... the remainder of the upper mandible of a dull yellow...

orange, with the exception of an indefinite mark of black which springs from each serrature, and a fine line of the same colour surrounding it near the base; lower mandible black, with the exception of the base, which is surrounded with pale yellowish orange; the head, back of the neck, throat, and chest black; all the upper surface, except a spot of scarlet on the rump, of a dull olive; primaries blackish brown; under surface pale straw-yellow with a slight tinge of green; thighs chesnut; naked space round the eyes and tarsi lead-colour. Total length about 16 to 17 inches; bill 4, wing 5½, tail 6¾, tarsi 1¾. (Gould.)

Mr. Gould's elegant figure of a male is taken from a specimen, supposed to be unique, in the Cabinet of Natural History at Munich.

Locality.—Brazils; probably near the Amazon.

Pteroglossus Humboldtii. (Gould.)

Pteroglossus pluricinctus.

***Description.*—(*Male.*)**—**A broad band of black advances from the nostrils along the whole of the culmen, and forms a narrow belt down the sides of the upper mandible at its base; the elevated basal margin of the bill is yellow; the sides of the upper mandible beautiful orange-yellow, fading into yellowish-white towards the tip; under mandible wholly black with a yellow basal ridge; head, neck, and chest black; whole of the upper surface, except the rump, which is scarlet, dark olive-green; breast marked with two broad bands of black, the upper separated from the throat by an intervening space of yellow dashed with red; a similar but broader space separates the two bands of black, the lower of which is bounded by scarlet, advancing as far as the thighs, which are brownish-olive; under the tail-coverts light yellow; naked space round the eyes, tarsi, and feet dark lead-colour.**

***Female.*—Differs from the male in having the ear-coverts brown, and a narrow belt of scarlet bordering the black of the throat.**

Total length 20 inches; bill 4½, wings 6½, tail 8½. (Gould.)

Locality.—Brazil.

The most characteristic figures of the *Ramphastidæ* known to us are those by Mr. Swainson, in his 'Zoological Illustrations,' and the highly finished plates in Mr. Gould's *Monograph*; the latter, from their size, beauty, and accuracy, have all the air of portraits.

Pteroglossus pluricinctus.

Upper figure, female; lower, male. (Gould.)

RAMPHO'STOMA, Wagler's name for the *Gavials.* [CROCODILE, vol. viii., p. 167.]

RAMPION (*Campánula Rapúnculus*) is a biennial plant, indigenous to Britain as well as to various parts of the continent of Europe. It has a long white spindle-shaped root, which may be eaten in its raw state, like a radish, and is by some esteemed for its pleasant nutty flavour. Both leaves and root may also be cut into winter salads. The seeds should be sown at the end of May, in rather light soil, and thinly covered. The roots will be fit for use throughout the following winter.

A different plant, the *Œnothera biennis*, is sometimes called German Rampion (*Rāpunzel Sellery*). Its roots are used like those of the above, and the plants are cultivated in the same manner as carrots or parsnips.

RAMPOOR. [HINDUSTAN, p. 219.]

RAMSAY, ALLAN, was born in 1685, of parents of the humblest class, at a small hamlet, or settlement of a few cottages, stated to be now in ruins, on the banks of the Glangonar, a tributary of the Clyde, among the hills that divide Clydesdale and Annandale. The parish was probably that of Crawford in Lanarkshire, through which the Glangonar flows, and where are situated Lord Hopeton's lead-mines, in which Ramsay's father is said to have been a working man, and he himself to have been employed when a child as a washer of ore. When he made his first appearance in Edinburgh, about the beginning of the last century, Allan was apprenticed to a barber; and he appears to have followed that trade for some years. In course of time however he exchanged it for that of a bookseller, led probably by a taste for reading which he had acquired. He seems to have early in life enjoyed considerable popularity as a boon companion, and we may presume that it was in this character that he first gave proof of his poetic talents. He gradually however obtained the acquaintance of many of the most distinguished persons both in the literary and fashionable circles of the Scottish capital; and in 1721 he published a volume of his poems, which was very favourably received by his countrymen. In 1724 he published, in two small volumes, 'The Evergreen, being a Collection of Scots Poems, wrote by the Ingenious before 1600. The materials of this collection (which has been lately reprinted) were chiefly obtained from the volume called the Bannatyne MS., preserved in the Advocates' Library; but Ramsay, who had little scholarship, and who lived in a very uncritical age as to such matters, has paid no attention to fidelity in making his transcripts, patching and renovating the old verses throughout to suit his own fancy. 'The Evergreen' was followed the same year by 'The Tea-Table Miscellany, or a Collection of Choice Songs, Scots and English,' in four volumes, which has been often reprinted. The edition before us, dated 1763 (London), is designated the twelfth. This collection, besides many new verses contributed by Ramsay himself and some of his friends, contains numerous old Scottish songs, which, he observes in his preface, 'have been done time out of mind, and only wanted to be cleared from the dross of blundering transcribers and printers.' His scouring however went the length in many cases of rubbing away the old song altogether; and his substitutions are by no means always a compensation for what he thus destroyed, though most of them are clever and spirited, and have acquired general currency among Scottish song-singers. No older copies, it ought to be stated, either printed or manuscript, are now known to exist of many of the songs professing to be antient preserved in this collection; and there can be little doubt that Ramsay was indebted for many of them merely to oral tradition. Ramsay afterwards wrote many more verses in his native dialect; but his only two original performances of any considerable pretension are his comic pastoral, the 'Gentle Shepherd,' published in 1729, and his continuation of the old Scottish poem of 'Christ's Kirk on the Green,' attributed by some to James I.; by others, with more probability, to James V. There is a good deal of rather effective though coarse merriment in the latter attempt. The 'Gentle Shepherd' is, as a whole, not very like anything else that Ramsay has written; but there seems to be no evidence for the notion which has been suggested, that in this instance he fathered the production of some other writer. The name of this supposed other writer, we believe, has never been so much as suggested or attempted to be guessed at; nor were any of the circumstances attending the publication suspicious or mysterious. The poem too, although more careful and elaborate than anything else that Ramsay has left us, is not without the wonted qualities of his manner, both good and bad. It has no more elevation or refinement than any of Ramsay's other works, though less that is offensively coarse or boisterous than some of them; both in the diction and the thought it flows easily and smoothly; and though there are not many happy touches, and no daring strokes, there is a general truth of painting about it in a quiet tone, which is very soothing and agreeable. It has also some humour, which however is rather elaborate and constrained.

Ramsay died in 1758, leaving a son of the same name, who acquired considerable distinction as a portrait-painter.

(See Currie's *Life of Burns*; and, for a very severe, indeed an outrageous critique of the 'Gentle Shepherd,' Pinkerton's *List of the Scottish Poets*, prefixed to his *Antient Scottish Poems*, 1786, vol. i., pp. 132, &c.)

RAMSDEN, JESSE, was born at Salterhebble, near Halifax, Yorkshire, in 1735. He was the son of an innkeeper. When nine years old he was admitted into the free grammar-school of Halifax; and after attending there for about three years, he was placed under the protection of an uncle, who resided in the north of Yorkshire. By him he was sent to a school conducted by Mr. Hall, a clergyman, who was in repute as a teacher of the mathematics, and under whom he attained to some proficiency in geometry and algebra. His studies were interrupted by his father apprenticing him to a cloth-worker at Halifax. At the age of twenty we find him engaged as a clerk in a cloth warehouse in London, in which capacity he continued till 1757-8, when his predilection for other pursuits led him to bind himself for four years to a working mathematical and philosophical instrument maker, named Barton, in Denmark Court, Strand. Upon the completion of his term, he engaged himself as assistant to a workman named Cole, at a salary of twelve shillings a week; but this connection was of short duration. He then commenced working on his own account, and his skill as an engraver and divider gradually recommended him to the employ of the leading instrument-makers, more particularly Nairne, Sisson, Adams, and Dollond. Ramsden subsequently married Dollond's daughter, and he received with her a part of Mr. Dollond's patent right in achromatic telescopes. His occupation afforded him frequent opportunities of observing the defective construction of the sextants then in use, the indications of which, as had been pointed out by Lalande, could not be relied on within five minutes of a degree, and might therefore leave a doubt in the determination of the longitude amounting to fifty nautical leagues. The improvements introduced by Ramsden are said by Piazzi to have reduced the limits of error to thirty seconds. This circumstance, added to the cheapness of his instruments, which were sold for about two-thirds the price charged by other makers, soon produced a demand which, even with the assistance of numerous hands, he found difficulty in supplying. In his workshops the principle of the division of labour was carried out to a considerable extent, and a proportionate dexterity was acquired by the workmen; but it is asserted that in none of these, even the most subordinate, and least of all in the higher departments, did the skill of the workmen surpass that of Ramsden himself. His attention was incessantly directed to new improvements and further simplification, the result of which was the invention of a dividing-machine, which has been already noticed under GRADUATION. The date of this invention is prior to the year 1766. At first it had many imperfections; but by repeated efforts of ingenuity throughout a period of ten years, they were successfully removed. In 1777 it was brought under the notice of the Commissioners of the Board of Longitude, by Dr. Shepherd, and by them a premium of 615*l.* was paid to the author, upon his engaging to divide 'sextants at six, and octants at three shillings, for other mathematical instrument makers. A description of the machine was immediately published, by order of the Board, under the supervision of Dr. Maskelyne (London, 1777, 4to.), and was shortly after translated into French by Lalande. A duplicate of the machine itself is said to have been purchased by the president, Bochard de Saron, and introduced into France concealed in the support of a table made for that purpose. (Weiss, *Biog. Univers.*) As early as 1788 no less than 983 sextants and octants had issued from Ramsden's workshop. In 1779 the description of another machine constructed by Ramsden for dividing straight lines by means of a screw was also published by order of the Board; but this invention does not appear to have been of much practical use. It was however in the construction of many of the larger class of astronomical instruments that Ramsden acquired most reputation, though they were probably least productive of pecuniary gain. The theodolite employed by General Roy in the English Survey was made by Ramsden, and no instrument of the kind that had been previously made would bear comparison with it. A similar remark is applicable to the equatorial constructed for Sir George Schuckburgh, which was also the largest that had then been attempted. Ramsden took out a patent for his new equatorial, and a description of it was published by the Hon. Stewart Mackenzie, brother to the earl of Bute, but his inventive genius seldom permitted him to construct two instruments alike. His telescopes, erected at the observatories of Blenheim, Mannheim, Dublin, Paris, and Gotha, were remarkable for the superiority of their object-glasses; and in his mural quadrants, furnished to the observatories of Padua and Vilna, Dr. Maskelyne was unable to detect an error amounting to two seconds and a half, a degree of accuracy which was then a matter of admiration among astronomers. Ramsden however always recommended that the mural quadrant should be superseded by the mural circle; and the circles erected in the observatories of Palermo and Dublin, the first of which was of five and the latter of twelve feet diameter, were constructed by him in accordance with this recommendation.

Among Ramsden's minor inventions and improvements may be enumerated his catoptric and dioptric micrometers (described in the 'Phil. Trans.,' 1779), the former of which was an improvement upon that of Bougier; optigraph, dynamometer (for measuring the magnifying powers of telescopes); barometer; electrical machine; manometer, assay-balance; level; pyrometer; and the method introduced by him for correcting the aberrations of sphericity and refrangibility in compound eye-glasses. (*Phil. Trans.*, 1783.)

Ramsden was elected a fellow of the Royal Society in 1786. In 1794 a similar compliment was paid him by the Imperial Academy of St. Petersburg; and the following year the Copley medal was awarded to him by the Royal Society, in testimony of the importance of his various ventions. By this time his health had become much impaired by his ardent devotion to his profession. In 1800 he was advised to visit Brighton, where he died, on the 5th of November of that year. From 1766 to 1774 his shop and residence was in the Haymarket; but in the latter year he removed to Piccadilly, where his business continued to be conducted after his decease.

In his habits we are told that he was temperate to abstemiousness, and that for many years he restricted himself to very few hours of repose. Most of the time that he could spare from the immediate duties of his profession was devoted to the perusal of works of science and literature. His memory was remarkably retentive, and at an advanced age he made himself sufficiently master of the French language to read Molière and Boileau. The fortune of which he died possessed was not considerable, and a large portion of it was directed by his will to be distributed among his workmen.

See CIRCLE; EQUATORIAL; GRADUATION; TRANSIT-INSTRUMENT; SEXTANT; &c.; and Pearson's *Practical Astronomy*, Lond., 1829, vol. ii., pp. 12, 18, 47, 181-5, 194-6, 255-6, 413-28, 519, 533-46, 558-60, and 573.

(Piazzi's *Account of the Life and Labours of Ramsden*, in a letter addressed by him to Lalande, and published by the latter in the 'Journal des Sçavans' for Nov., 1788, p. 744. This interesting letter was written by Piazzi while urging the progress of his mural circle, the construction of which had been undertaken by Ramsden, but the advance of which towards completion does not appear to have kept pace with Piazzi's wishes; and though it doubtless contains no unmerited eulogium, it seems to have been intended by Piazzi to act as a stimulant. *Philosophical Magazine*, vol. xvi.; *European Magazine*, February, 1789; *Biog. Univers.*; and the *Communication of the Rev. L. Dutens to Dr. Aikin*, in *General Biography*, art. 'Ramsden.')

RAMSEY. [MAN, ISLE OF.]

RAMSGATE, a town in the Isle of Thanet in Kent, 71 miles from London-bridge, through Dartford, Rochester, and Canterbury. The ville of Ramsgate, comprehending 260 acres, was included formerly in the parish of St. Lawrence, in the hundred of Ringslow or Thanet, in the lathe of St. Augustine; but provided separately for its own poor: in 1827 it was made a distinct parish. The ville is a member of the Cinque-Port of Sandwich. Ramsgate was antiently a poor fishing-town, consisting of a few meanly-built houses, built on the coast of the Isle of Thanet, which here fronts the south-east: it had a small wooden pier. After the Revolution of 1688, some of the inhabitants engaged in the Russian trade, by which they acquired wealth, and this led to the improvement of the town. When the practice of families from London and elsewhere resorting to the seaside became general, Ramsgate was one of the earliest frequented spots, though for some time eclipsed by the superior attractions of Margate. The improvement of the harbour by the erection of the piers and other works in the middle and latter part of the last century, gave another impulse to the prosperity of the town. Early in the present century a stone lighthouse was erected on the head of the west pier; a small battery is fixed at the head of the east pier. The east pier is one of the longest in the kingdom, extending 2000 feet; the western pier extends about half that length: they are built of Portland and Purbeck stone and Cornish granite. The harbour includes an area of 48 acres, and furnishes a convenient shelter for vessels which are obliged by heavy gales to run from the Downs. It is provided with a basin and floodgates in the upper part of the harbour for scouring it from the drifted sand or mud.

The old part of Ramsgate is situated in one of those natural depressions (called in the Isle of Thanet 'gates,' or 'stairs') in the chalk, which open upon the sea. This part of the town is low compared with the higher parts on each side of it. The streets in the old part of the town are narrow and indifferently built. The newer part of the town, from its elevated site on the cliffs, commands an extensive sea-view, and consists of several streets macadamized and lighted with gas. Many of the houses are very handsome: some are arranged in streets, terraces, or crescents, while others are detached villas. At present (1840) a considerable number of houses are building. There are bathing-rooms, assembly-rooms, boarding and lodging houses, a handsome new church, a chapel-of-ease, and several dissenting meeting-houses.

The population of the ville of Ramsgate, including the town, was, in 1831, 7985. There is considerable coasting trade; coal is imported in considerable quantity; and ship building and rope-making are carried on. It is observable as indicating the commercial character of the place, that though the population of Margate exceeds that of Ramsgate by 2300 or 2400, there are not half as many persons engaged in retail trade or handicraft as at the latter place. The markets are on Wednesday and Saturday. A considerable fishery is carried on; in the summer steam-boats sail regularly between London and Ramsgate.

The living of Ramsgate is a vicarage, of the clear yearly value of 400*l.*, in the gift of the vicar of St. Lawrence, the mother church.

There were, in 1833, two infant schools, with 217 children of both sexes; a national day and Sunday school with 150 boys and 100 girls; twenty day-schools, estimated to contain about 525 children; six boarding-schools, supposed to contain 170 children; and three Sunday-schools, two of them containing 300 children; from the other no return was made.

RAMSON (*Allium ursinum*), a species of garlic found wild in many parts of Britain, and formerly cultivated in gardens; but its use is superseded by the *Allium sativum*, a native of Sicily, which is the *Garlic* now in cultivation.

RAMTILLA, a genus of plants of the natural family of Compositæ, and subtribe Helianthеæ, so called from the Indian name *ram-tilla*, by which the oil of its seed is designated. The plant is remarkable for the number of names by which it has been described by botanists. Of these we need only mention the *Verbesina sativa* of Roxburgh, and the *Ramtilla oleifera* of De Candolle. Cassini had however previously formed it into a new genus, and under the name of Guizotia 'dedicated it to the celebrated historian, then minister of public instruction.' This name, being prior to that of Ramtilla by a year or two, is now retained as that of the genus. De Candolle, having obtained specimens and seeds from various countries, discovered that the Indian plant was identical with one from Abyssinia, which has been mentioned by Bruce under the name of Polymnia frondosa. The fact is interesting in a plant cultivated in both countries for the same purposes, and forming one of the links which indicate the connection which existed in early times between India and Upper Egypt. This plant is cultivated in different parts of India, from October to March, in fields, for the sake of the seed, from which an oil is expressed, and used as a substitute for that of the Sesamum, which is considered the best kind. It is used both in dressing food and as a lamp oil.

RAMUS, PETER (PIERRE DE LA RAME'E), was born in a village in Picardy, in the year 1502, according to one account, and in the year 1515 according to another. His parents were extremely poor, and the future philosopher was set when a boy to tend sheep. Disgusted with this employment, and having an ardent desire to get knowledge, he ran away from his parents to Paris. After some time, and after he had encountered much misery, one of his uncles offered some pecuniary assistance, and Ramus now entered the College of Navarre as a servant. He made great progress in all studies, with very little assistance from masters. At the completion of his course, when he presented himself for the degree of master of arts, he undertook as an exercise what then seemed the almost impious task of showing that Aristotle was not infallible. This was the beginning of the anti-Aristotelian opinions by which Ramus afterwards gained his notoriety and fame. The exercise was adjudged successful, and Ramus henceforth devoted himself to the study of the works of Aristotle as to the object of his life. In 1543 he published his new system of logic, with strictures on the logic of Aristotle. The publication of this work exposed him to great obloquy. He was charged with impiety and sedition, and with a desire to overthrow all science and religion, through the medium of an attack on Aristotle. On the report of an irregular and partial tribunal, appointed to consider the charges made against him, the king ordered his works to be suppressed, and forbade his teaching or writing against Aristotle on pain of corporal punishment. Ramus availed himself of the leisure which the compulsory cessation of his lectures procured for him, to study mathematics and prepare an edition of Euclid. Shortly afterwards he began a course of lectures on rhetoric at the College of Presles, the plague having driven away numbers of students from Paris. He was named Principal of this college, and the Sorbonne ineffectually endeavoured to eject him on the ground of the royal prohibitory decree. This decree wa cancelled in 1545, through the influence of the Cardinal de Lorraine, to whom he had dedicated his edition of Euclid. He now began a course of mathematics in Paris. In 1551, he was named by the king (Henri II.) professor of philosophy and eloquence in the College of France. During the next ten years, he published a Greek, Latin, and French grammar, and several treatises on mathematics, logic, and rhetoric. Ramus had embraced Protestantism, and now shortly again brought upon himself great trouble by the zeal with which he advocated the new doctrines. Charles IX. offered him an asylum at Fontainebleau; but while he was absent from home, his house was pillaged and his library destroyed. He returned to Paris in 1563, and resumed possession of his royal chair. Civil troubles again drove him away from Paris, and in 1568 he asked permission to travel. He went to Germany, and was received everywhere with honour. He gave lectures on mathematics at Heidelberg, and while in this town he made public profession of Protestantism. Shortly after his return to Paris, he fell a victim in the massacre of St. Bartholomew.

Although Ramus had many merits as a philosopher, and did much good by his opposition to the Aristotelian philosophy, which then held men's minds in bondage, he was wanting in depth and caution, and his strictures on Aristotle are by no means altogether just. He had many followers. The influence of Melanchthon, on the other side, did not prevent the progress of his system of logic in the German universities. France, England, and particularly Scotland, were full of Ramists. Andrew Melville introduced the logic of Ramus at Glasgow.

The following is a list of the principal works of Ramus: 1, 'Institutiones Dialecticæ Tribus Libris distinctæ;' 2, 'Animadversiones in Dialecticam Aristotelis;' 3, 'Rhetoricæ Distinctiones in Quintilianum;' 4, 'Arithmeticæ Libri Tres;' 5, 'In Quatuor Libros Georgicorum et in Bucolica Virgilii Prælectiones;' 6, 'Ciceronianus.' (A life of Cicero, interspersed with many philological remarks on the Latin language, and strictures on the state of education in France.) 7, 'Scholæ Grammaticæ Libri Duo;' 8, 'Grammatica Latina;' 9, 'Grammatica Græca quatenus à Latina differt;' 10, 'Gramère Fransoeze;' 11, 'Liber de Moribus Veterum Gallorum;' 12, 'Liber de Militia Julii Cæsaris;' 13, 'Commentarius de Religione Christiana, Libri Quatuor;' 14, 'Præfationes, Epistolæ, Orationes' (Paris, 1599, and Marburg, 1599) The Greek Grammar of Ramus received considerable additions from Sylburgius.

The above list is taken from the article 'Ramus,' in the *Biographie Universelle*. For a complete list of the works of Ramus the reader is referred to Niceron (*Mém.*, tom. xiii.).

RAMU'SIO, GIAMBATTISTA, was born at Treviso in the Venetian State, in 1485, of a family originally from Rimini, which produced several men of learning. He filled several offices under the republic, and became secretary to the Council of Ten. Having undertaken a collection of the most important narratives of voyages and travels performed in distant counties both in antient and modern times, he translated into Italian those that had been written in other languages, and added his own remarks and several dissertations, which show that he possessed very extensive general information for the age in which he lived. He was a friend of Bembo, Fracastoro, and other learned contemporaries. His work is entitled 'Raccolta di Navigazioni e Viaggi,' 3 vols. fol. The first volume was printed by Giunti at Venice, in 1550; another volume appeared in 1556, and a third in 1559, after Ramusio's death, which took place at Padua, in July, 1557. Subsequent editions appeared with the addition of several travels which had not appeared in the first. The most complete edition is that of 1606. The following list of contents will convey an idea of the value of the work:—Vol. i., 'Leo Africanus's Description of Africa; Cadamosto a Venetian navigator, preceded by a Discourse by Ramusio; Sintra, a Portuguese narrative; Hanno's Periplus; Navigation from Lisbon to St. Thomé, by a Portuguese pilot; Ramusio, a Discourse on the Navigation of the Portuguese to the East Indies; Voyage of Vasco de Gama in 1497, written by a Florentine; Pedro Cabral Alvarez, voyage from Lisbon to Calicut in 1500, written by a Portuguese pilot; Amerigo Vespucci, two letters to Pietro Soderini; a Summary of Vespucci's Voyages; Thomas Lopez, a Portuguese, Voyage to the East Indies; Giovanni da Empoli, a Florentine, Journey to India; Ludovico Barthema of Bologna, Itinerary, preceded by a Discourse by Ramusio; Iambolus, Voyage extracted from Diodorus, with a Discourse by Ramusio; Andrea Corsali, a Florentine, Two Letters to Julian and Lorenzo de' Medici; Alvarez, Travels to Ethiopia, with the submission of Prester John to Pope Clement VII.; Ramusio, Discourse on the Rise of the Nile, with a reply by Fracastoro; the Voyage of Nearchus translated from Arrian's text; Journey of a Venetian from Alexandria to Diu in India in 1538; Arrian's Navigation from the Red Sea to India; Barbosa, a book of travels to the East Indies; a brief account of Kingdoms and Towns between the Red Sea and China, translated from the Portuguese; Antonio Conti, a Venetian, Journey to India, written by Poggio Bracciolini; Jeronimo da San Stefano, a Genoese, his letter written from Tripoli in 1499; Ramusio, Discourse on the Voyage round the World by the Spaniards; Maximilian of Transylvania, Epistle concerning the Navigation of the Spaniards; a short account of the Voyage of Magalhaens; Pigafetta, Voyage round the World; the Navigation of a Portuguese who accompanied Edward Barbosa in 1519; Ramusio, a Discourse concerning the Voyages to the Spice Countries; Juan Gaetan, a Castilian pilot, Discovery of the Moluccas; Information concerning Japan, by the Portuguese Jesuits; João de Barros, Chapters extracted from his History.'

Vol. ii. contains 'Marco Polo's Travels, with a preface by Ramusio; Hayton, an Armenian, Discourse on the origin of the Great Khan and the condition of the Tartars; Angiolelli, Life and Actions of Hussan Cassan; the Travels of a Merchant into Persia in the years 1517-20; Giosafat Barbaro, a Venetian, Journey to the Tana (the river Tanais) and into Persia; Ambrosio Contarini, Journey into Persia; Alberto Campense, Letters to Clement VII. concerning the affairs of Muscovy; Paul Giovio, Reports on the affairs of Muscovy, by him collected; Herbestein, Commentaries on Muscovy and Russia; Arrian's Letter to Hadrian concerning the Euxine; Interiano, a Genoese, on the habits and manners of the Zythi, called Circassians; Hippocrates, extract of his Treatise on Air and Water, in which he speaks of the Scythians; Piero Quirino, a Venetian, Account of his Voyage and Shipwreck; Sebastian Cabota, Navigation in the Northern Seas; Caterino Zeno, a Venetian, Travels to Persia; Niccolo and Antonio Zeno on the Discovery of Iceland; Travels into Tartary by some Dominican monks; Olderico da Udine, Two Journeys into Tartary; Guagnini, a Venetian, Description of European Sarmatia; Matthew Micheow of Cracow, Description of the two Sarmatias.'

Vol. iii.:—'Pietro Martire of Angleria, extract from his History of the New World; Oviedo, extract from his History of the West Indies; Hernan Cortez, Narrative of his Conquest of Mexico; Pedro de Alvarado, two letters to Hernan Cortez; Diego Godoy, a letter from New Spain; Narrative of one of Cortez's companions concerning Mexico, with two maps, one of the Great Temple, and another of the Lake; Alvaro Nuñez, Narrative of the Indies and of New Galicia in 1527-36; Guzman on the Conquest of New Spain; Francisco Ulloa, Voyage in the Mar Vermejo, or Sea of California; Vasquez de Coronado, Narrative of a Journey to Cevole, or the Kingdom of the Seven Cities; Alarcon, Voyage to discover the Kingdom of the Seven Cities in 1540; Ramusio, Discourse on the Conquest of Peru; Narrative of a Spanish Captain concerning the Conquest of Peru; Francisco Xeres, Narrative of the Conquest of Peru and New Castile; Narrative of a Secretary of Francesco Pizarro concerning the Conquest of Peru; Gonzalo de Oviedo, Navigation of the river Marañon; Ramusio, Discourse concerning New France; Giovanni da Verazzano, a Florentine, Narrative written from Dieppe, in July, 1524; Discourse of a great Naval Captain concerning the Navigation of the West Indies; Jacques Cartier, First and Second Narrative of Voyages to New France; Cesare de Federici, Voyage to the East Indies and beyond India; Three Voyages of Hollanders and Zealanders to China, New Zembla, and Greenland.'

Among the above series are several curious narratives which are not found in any other collection. Ramusio left materials for a fourth volume, which unfortunately were destroyed in a fire which broke out in the printing-press of Giunti, in November, 1557.

(Camus, *Mémoires sur les Collections de Voyages*; Gamba, *Serie dei Testi di Lingua*.)

RANDAZZO. [MESSINA.]

RANDERS is a thriving Danish trading town, in the diocese of Aarhuus, in the province of Jutland. It is situated in 56° 28′ N. lat. and 10° 3′ E. long., near the

Balle, on the river Gudon, which is here navigable. It is a walled town with seven gates, and next to Aarhuus, is the most considerable place in Jutland, having a population of 8400 inhabitants. There is one church, a large hospital, a grammar-school, and an Agricultural Society. The inhabitants manufacture gloves, stockings, woollen cloth, earthenware, and lampblack; calico-printing, brewing, and brandy-distilling are carried on to a considerable extent. There are other vinegar manufactories and one sugar-house. This place has a very brisk trade, especially in corn.

RANDOLPH, THOMAS, an English poet, was born in the year 1605, at Badby in Northamptonshire. He was the second son of William Randolph of Little Houghton, steward to Edward lord Zouche, by his first wife Elizabeth, daughter of Thomas Smith of Newnham in the same county.

He was educated at Westminster school, and thence elected scholar of Trinity College, Cambridge, in the year 1623. He was afterwards made fellow on the same foundation, and admitted to an ad eundem degree at Oxford in 1631. After some stay at Cambridge, he came to London, where he was much noticed by Ben Jonson, who called him his adopted son. He became intimate also with many of the other wits of that day. The promise of his youth was blasted by a course of dissipation and extravagance, which shortened his life prematurely. He died while on a visit to a friend at Blatherwick in Northamptonshire, where he was buried, March 17, 1634-5, and his memory honoured by a monument erected at the charge of Sir Christopher (afterwards lord) Hatton of Kirby.

Randolph's 'Poems, Translations, and Plays,' were published in London, 1634, 4to., and his 'Poems, with the Muses' Looking-Glass and Amyntas,' at Oxford, in 1638, 4to. There have been several other editions published since, both in London and at Oxford. His plays are:—'Aristippus,' and 'The Conceited Pedlar,' published together in 1630, 4to.; 'Jealous Lovers,' 1632, 4to.; 'The Muses' Looking-Glass,' Lond., 1638, 4to.; 'Amyntas,' Oxford, 1638, 4to.; 'Hey for Honesty, Down with Knavery,' a comedy. 'The Prodigal Scholar,' a comedy, and 'The Drunken Gentleman,' a Latin play in the style of Plautus, have been attributed to him.

Randolph's writings are the production of a mind well imbued with classical literature, and he has in many passages not unskilfully interwoven the language and imagery of the best authors of antiquity. He wrote Latin verse with ease and fluency, and translated from Claudian with considerable elegance. But his English compositions are not free from the faults imputed to most of his contemporaries, and are often disfigured by licentiousness, obscurity, and strained conceits, exhibiting more learning and ingenuity than good taste. They consist of addresses to different friends, epigrams, translations, and amatory poems. His dramas present very few attractions to the modern reader. The characters are either mere impersonations of virtues and vices, or feeble and pedantic travesties from Greek and Roman comedy. The plots are perplexed and devoid of interest, and the dialogue seldom rises above mediocrity, though occasionally relieved by passages showing much original power of description. The most popular of his plays is the 'Muses' Looking-glass,' which was re-acted in the last century. For further particulars of his life see Baker's *Parental Register* (which contains a curious anecdote of his first interview with Ben Jonson); Wood's *Athenae Oxonienses*; Baker's *Hist. of Northamptonshire*. His works are reviewed in the *Retrospective Review*, vol. vi.; and a list of them is given in Watt's *Bibliotheca Britannica*.

RANELLA. (Malacology.) [SIPHONOSTOMATA.]

RANGE. [GUNNERY; PROJECTILES.]

RANGER (*Rangiator*), an ancient officer in the king's forests and parks, appointed by patent, and enjoying certain fees, perquisites, and other advantages. His duty was of three kinds: 1, to make daily perambulations, to see, hear, and inquire concerning any wrong doings in the limits of his bailiwick; 2, to rechase any of the beasts which had strayed beyond the limits of the forest or chase; and, 3, to present all transgressions at the next forest-court.

RANGOON is the most commercial port of the Birman Empire. It is near 16° 46' N. lat. and 96° 18' E. long., and is built on the most eastern branch of the river Irawadi, about twenty-six miles from the sea. About two miles below the town, the river divides into two arms, of which the eastern, running nearly due east, is called Syriam River; and the western, running nearly due south, Rangoon River. Both of these branches are navigable, but the Rangoon River is generally preferred. Though the navigation is somewhat intricate, the difficulties are easily overcome by the assistance of tolerable pilots. Vessels of 1200 tons burden have proceeded to the town. This western branch is the only one of the Irawadi which is navigable for large vessels, except that of Bassein, which has the disadvantage of being nearly dry above the town of Bassein during the dry season, whilst the eastern branch may always be navigated by large river-boats; consequently Rangoon has the advantage of an uninterrupted communication with the upper provinces at all seasons.

The town is on the left bank of the river, at a place where it runs nearly due east and west. From the banks of the river the ground continues to rise gradually for more than two miles to the foot of the hill on which the grand Dagung Pagoda is built, the bottom of which appears to be 70 or 80 feet above the level of the Irawadi. The town and suburbs extend about a mile along the bank of the river, but the houses are very unequally scattered over this area. The streets are narrow, but clean and well paved. The houses are raised on posts, the smaller supported by bamboos and the larger by strong timbers. There are a few brick houses, chiefly belonging to Europeans, who pay a heavy tax for that privilege: no subject of the Birman emperor is permitted to erect a brick building. These brick houses are built within the myo, or city, which is an irregular quadrangle, surrounded by a stockade 14 feet high, and composed of heavy beams of teak timber. The north and south faces of this stockade are 1143 yards long; the east 376, and the west 197 yards. It has in some places a stage to fire musketry from, through embrasures or loopholes. On the south side of the stockade towards the river is a ditch, over which there is a causeway. The ditch is about 60 or 80 yards from the banks of the river. In the interior of the stockade are three wide and clean streets running east and west, and three smaller ones crossing them and fronting the gates on the south face.

Two narrow roads paved with brick lead from the northern face of the stockade to the great pagoda, Shwe Dagung, and along the sides are built a number of *zedis*, or monuments in honour of Buddha. In form they may be compared to a speaking-trumpet standing on its base. The lower part is generally a polygon, and the shaft or upper part is round, the apex being ornamented with an iron net in form of an umbrella, called a *ti*. The Shwe Dagung is in the same style as the rest, but richly gilt all over. It is said to be about 370 feet high, and is surrounded by an enclosure, in which is an immense bell of very rude fabric. This pagoda is a place of pilgrimage, frequented by many strangers, especially Shans, who live in the country east of the river Saluen.

Rangoon is very convenient for ship-building, as the tide rises from 18 to 24 feet, and the great teak-forests are near it. The timber may be floated down the whole way from the forests near Sarwa to Rangoon. According to Crawfurd, not less than 111 square-rigged vessels of European construction were built there from 1786 to 1824. Some of them were from 800 to 1000 tons burthen.

Rangoon was built by Alompra, after the destruction of Pegu and Syriam in 1755, and the choice of the site shows the sagacity of the conqueror. Besides its advantageous situation for commerce, the elevated ground on which it is built secures it from being inundated by the tropical rains, to which all the low lands of the delta of the Irawadi are subject. The climate is temperate, agreeable, and salubrious. The place at first rose slowly. Even at the beginning of the present century the number of vessels that cleared out was only from 12 to 25 annually. But between 1811 and 1817 the number increased to 55 and 56. From 1817 to 1822 the average was 40 ships, and in the last-mentioned year 56. Since the time of its occupation by the British (from 1824 to 1826) its commerce with Calcutta and other British possessions in India has been continually increasing. The most active commerce is carried on with Chittagong, Dacca, Calcutta, Madras, Masulipatam, the Nicobar Islands, and Pulo Penang; there is also some trade with Bombay and the Persian and Arabian gulfs. The articles exported are teak-wood, catechu, stick-lac, bees'-wax, elephants' teeth, raw cotton, orpiment, gold, silver, rubies, and horses. The most important of these articles is teak-timber, and Calcutta is the principal mart for it. Raw cotton of superior quality goes in great quantity to Dacca, where it is used in the fabrication of the finest muslins. The principal imports are cotton piece-goods, from Britain, Bengal, and Madras, British woollens, iron, steel, quicksilver, copper, cordage, borax, sulphur, gunpowder, saltpetre, fire-arms, coarse porcelain, English glass-ware, opium, tobacco, cocoa and areca nuts, sugar, and spirits. Crawfurd estimated the value of the imports before 1823 at 300,000*l.*, and that of the exports at the same sum. According to a census taken by Crawfurd in 1826 the town and suburbs contained a population of 8666 individuals, exclusive of strangers.

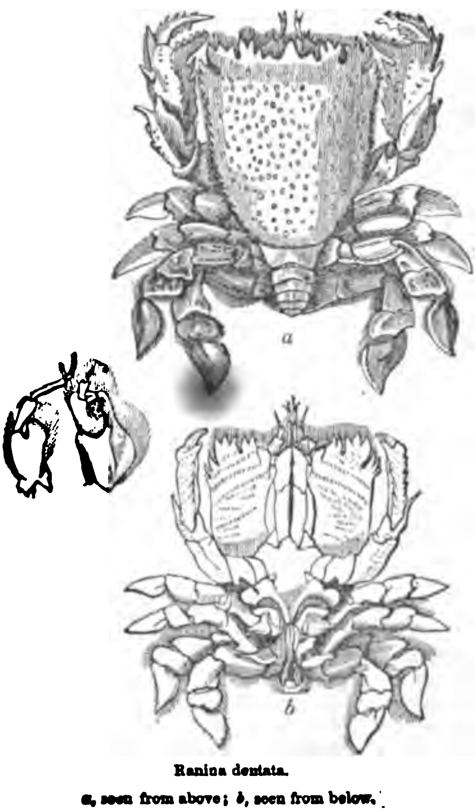
RA'NIDÆ. [FROGS, vol. x.] The reader should refer to Mr. Bell's interesting *History of British Reptiles*, where the experiments of Edwards proving the existence of cutaneous respiration in the frog after the possibility of communication with the lungs was prevented, are recorded, and many very valuable remarks are concentrated.

RANINIANS, the name by which M. Milne Edwards designates the fourth tribe of the family *Apterura*, belonging to the section of Anomourous Decapod Crustaceans.

This tribe, in its general form and in the conformation of its feet, approaches very closely to the Hippians, and especially to the *Albuneæ*. [HIPPA.]

The *carapace* of the *Raninians* is convex laterally, nearly straight from before backwards, wide and truncated anteriorly, and gradually narrowed backwards. The ocular peduncles are lodged in the orbits, but are bent (coudés), and composed of three moveable pieces. The *internal antennæ* have no fossets, and are not capable of bending themselves back under the front; the external antennæ are very short and very stout at their bases. The external *jaw-feet* are very much elongated, but not pediform, and behind their insertion the pterygostomian regions of the carapace unite themselves to the sternal plastron, without leaving any aperture for the entry of the water into the branchial cavity. The sternal plastron is very large anteriorly, but becomes linear between the third or fourth last pair of feet. The anterior feet are very much compressed, and their immoveable finger projects but very little, so that the moveable finger is bent back against the anterior border of the hand, nearly as in the subcheliform feet. The succeeding feet are all flattened, very wide, and terminated by a great lamellar joint, like that of the natatory feet of the



Ranina dentata.
a, seen from above; b, seen from below.

swimming *Brachyura*: the two last pair are inserted more or less high above the preceding, above which they bend themselves back. The abdomen is very small, and in the male does not even cover the appendages fixed near its base. (M. E.)

M. Milne Edwards makes this tribe consist of three genera, thus characterized:—

Raninians having the sternal plastron.	Linear between the base of the feet of the second pair. Second joint of the external antennæ	Carrying on the external border a great auriculiform prolongation.	Ranina.
		not enlarged externally.	Ranilia.
	Very wide between the base of the second pair of feet, which are widely separated from the third pair.		Raninoïdes.

Ranina dentata may be taken as an example of the tribe.

Locality.—The Indian Seas; Isle of France.

Habits.—Rumphius states that it comes to land, and creeps even to the tops of houses (sur le faîte des maisons). (M. E.)

M. Milne Edwards remarks that the *Cancer dorsipes* figured by Rumphius, and confounded by most modern authors with *Raninoïdes lævis* and *Albunea Symnista*, appears to belong to this genus.

In the neighbourhood of this tribe M. Milne Edwards would place *Eryon Caribensis* of Fréminville (*Ann. des Sciences Nat.*, 1st series, tom. xxv., p. 275, pl. 8, B).

FOSSIL RANINIANS.

The fossil designated by Ranzani as *Ranina Aldrovandi* belongs, in the opinion of M. Milne Edwards, to the tribe of *Raninians*, and may be referred to the genus *Ranina*.

RANSOM, a word common to the French (rançon) and English languages, the sense of which is a sum of money paid for the redemption of a captive.

The paying of ransoms is an event of frequent occurrence in the middle-age history, and indeed may be traced in the history of the older nations. Nothing appears on the first view more reasonable, or would more naturally arise out of the relations of two parties in a state of hostility, than that compensation of some kind should be made for the restoration of prisoners, which compensation was most easily estimated and discharged by means of the common medium of exchange. In modern warfare we hear little of ransoms. It rarely happens that a person is taken captive whom it is of importance to redeem; and when prisoners are to be redeemed, it is usually done by way of exchange, and those who remain over, at the conclusion of a war, are usually delivered up as a part of the concession of the party in whose favour the difference is found to be.

In the indentures of military service in the middle-age period, as in the wars of Henry V. for instance, it was a usual stipulation that, while the ransom of persons of inferior condition taken in the war was allowed to those by whom they were captured, the ransom for persons of rank was to belong to the king.

The ransoms demanded for persons of eminence were often very large sums of money; so much beyond the power of any family, however great, to command by the ordinary resources, that the persons who held lands of them were called upon to contribute in proportion to the extent of land held. It was one of the three casual occasions of expense when this kind of extraordinary aid was demanded as of prescriptive right by the lord; the other two being on occasion of knighting the eldest son, and of marrying the eldest daughter. In France these casual payments were required of the tenant on other occasions.

The ransom paid for King Richard I., when he was a captive in the hands of the emperor Leopold, was no less a sum than 100,000*l.* To raise this sum an aid of twenty shillings was required of each knight's fee, and the clergy contributed liberally. This was the only occasion on which England had to pay for the redemption of its king. The ransom of David Bruce, king of Scotland, in the reign of Edward III., was 100,000 marks, which sum was paid by instalments, usually of 4000*l.* By the treaty of Bretigny it was stipulated that a sum equal to 500,000*l.* should be paid to King Edward III., which was in fact the ransom money for John, king of France, his prisoner. These three are the most remarkable ransoms in English history.

RA'NULA is a tumour formed beneath the tongue, and probably resulting from an obstruction of one or more of the ducts of the sublingual salivary glands. The tumour is usually of a rounded form, with a smooth polished surface similar to that of the adjacent mucous membrane. When small, such a tumour produces so little inconvenience, that it is usually not discovered till it has existed for some time. As they increase in size however, these growths, though seldom attended with pain, produce great inconvenience, by obstructing all the movements of the tongne. They usually burst when they have attained the size of a walnut, but they sometimes continue to increase beyond this size, and have been seen large enough to contain a pint of fluid. Their most usual contents are a transparent yellowish viscid fluid, resembling in consistence the white of an egg; sometimes however the material within them is much thicker, and sometimes mixed with portions of earthy matter, similar to the larger masses by which the salivary ducts are occasionally blocked up.

The treatment of Ranula consists in making a free incision into the front of the tumour, so as to let out all its contents. Means must then be adopted to prevent the edges of the wound from uniting again; and the best plan for this purpose is to rub the surface of the cyst with nitrate of silver (lunar caustic). If the wound be not prevented from uniting, the tumour will form again, and the same proceedings must again be adopted for its cure.

RANUNCULA'CEÆ form a tribe of plants founded on the common crowfoot, or buttercup, but embracing a large variety of different structures within its limits. The essential character of this order is to have numerous indefinite stamens growing from below the pistil, disjoined carpels, a minute embryo lying in abundant albumen, and an annual, or at least nearly herbaceous stem. Great numbers of species answer to this description, and, when combined, form a very natural assemblage. All are more or less acrid and poisonous, and some vehemently so, as aconite and hellebore; others are beautiful with their gay flowers, as the pæony, ranunculus, larkspur, and columbine: many however are mere weeds. The most striking variation that takes place from the usual form of this order is when the calyx or corolla becomes unusually formed, and more or less imperfect. When this occurs, as in larkspur and aconite, the general resemblance of such plants to the regular portions of the order is much obscured. Occasionally the petals are not present, as in clematis, and thus additional evidence is afforded of the comparative unimportance of petals in forming the great suborders of Exogens.

RANZ DES VACHES ('Kuhreihen' in German) is the name of certain simple melodies which are great favourites with the mountaineers of the Alps of Switzerland, and which are commonly played upon a kind of long trumpet called the Alp-horn. The sounds of these tunes, as well as the words which are set to them, are expressive of the scenes and business of pastoral life; the hut, the roaring torrent, the bellowing of the cattle, and the tinkling of the bells which are suspended from their necks; and the associations which they thus recall to the minds of the natives when they are in foreign countries, often produce that unconquerable longing for home which is said to have been especially remarked among the Swiss soldiers on foreign service; for this reason, the bands of the Swiss regiments in foreign service were forbidden to play the Ranz des Vaches. Theodore Zwinger, of Basle, wrote, in 1710, a 'Dissertation on Nostalgia,' in which he gave the music of the Kuhreihen of Appenzell, which is one of the oldest, and which was introduced into England in the time of Queen Anne, who had it often played by her band. The words begin thus: 'Wänder iha, wänder iha, wänder iha, Lo....ba, Alsamma mit nama, alsamma mit nama, die alten, die jungen, die alten alisamma, Loba, Loba, Loba.' Each of the various pastoral districts, the Oberland, the Emmenthal, the Entlibuch, the Appenzell, has its Kuhreihen. The western or Romand districts of Switzerland have their Ranz des Vaches in their respective patois or dialects. The following is a specimen of that of Gruyères in the canton of Fribourg: 'Lé-z-armailli dei Colombette—Dé bon matin sé san leha—Ha ah! Ha ah!—Liauba, Liauba, por arià—Vinidé tote—Bhantz et nairé—Rotz et motailé,' &c.

In recent times the words of the original Ranz des Vaches have appeared too rude to refined ears, and more sentimental expressions have been substituted. This is the origin of the pretty air which is often heard in the societies of the Swiss towns, 'Quand reverrai-je un jour—tous les objets de mon amour? nos clairs ruisseaux, nos coteaux, nos hameaux, nos montagnes,' &c., which reminds the English hearer of his own 'Home, sweet home.'

A collection of the various Ranz des Vaches and other Swiss airs has been published: 'Sammlung von Schweizer Kuhreihen and Volksliedern,' Bern, 1818. Tarenne has written 'Recherches sur les Ranz des Vaches,' Paris, 1813. See also Laborde, 'Essai de la Musique ancienne et moderne;' and Ebel, 'Schilderung der Gebirgsvölker der Schweiz.'

RAPA'CES, M. Temminck's name for the *Birds of Prey*. [RAPTATORES; RAPTORES.]

RAPE is defined to be the having unlawful carnal knowledge of a woman by force and against her will; and it is a capital felony. It is doubtful whether fraud is equivalent to force for the purpose of constituting this offence; as where a man takes advantage of circumstances which induce a woman to suppose he is a husband; but if he obtains her consent by menacing her with death, or by duress, it is clearly rape. A person under fourteen years of age is in law presumed to be incapable of perpetrating this offence: this presumption however is based on physical grounds entirely, so that such a person, by assisting others of maturer age, may render himself liable to the full penalty of the law as a principal in the second degree. In the case of a female under ten years of age, whether the act takes place with or without her consent, it is equally punishable as rape; if she be above ten and under twelve years of age, her consent reduces the act to a misdemeanour punishable by imprisonment and hard labour for such term as may be awarded.

An assault with intent to commit a rape is a misdemeanor punishable by imprisonment for any term not exceeding two years, and with or without hard labour, at the discretion of the court before which the offender is convicted. Upon a trial for the capital offence, where the evidence is incomplete, the prisoner may be convicted of a misdemeanor.

RAPE. This plant, which is of the cabbage tribe, is cultivated like cole, or colza, for the sake of its seeds, from which oil is extracted by grinding and pressure. It is also extensively cultivated in England for the succulent food which its thick and fleshy stem and leaves supply to sheep when other fodder is scarce.

The mode of cultivation of the colza and rape for seed is nearly the same. The colza takes a longer time to come to maturity, and produces more seed. The rape grows on less fertile soils, and may be sown in spring as well as in autumn. Both are hardy, and resist the winter's frost.

The colza (Brassica oleracea, or campestris) is a plant which grows with a strong branching stem, three or four feet high, and requires room to spread; the plants are therefore raised in a seed-bed, and transplanted when they have acquired a certain size. When rape (Brassica napus) is cultivated for the seed, it is treated in the same manner; one description will therefore serve for both.

The seed-bed, where the cultivation is on a small scale, is usually prepared by digging or trenching with the spade, in a good loamy soil, neither too sandy nor too wet. A large proportion of rotten dung is spread evenly over it, and dug in six inches deep, and the surface is raked fine. The seed is sown broad-cast or in drill; the latter is the best method: it is then slightly covered with the rake; and if the ground will allow of it, without risk of its being bound too hard in case of dry weather, it is well rolled or trod with the feet. The seed must not be sown too thick; and the plants, as soon as they have six leaves, must be thinned to a distance of four or five inches in the rows, which will make them stronger and better furnished with roots. One acre of seed-bed will furnish plants for ten acres or more. The seed is sown in July or August, that the plants may not run to seed the same year, which they are apt to do if sown early; and they are transplanted in September or October, on land which has already borne a profitable crop. As this crop is a substitute for a fallow on rich heavy land, too much pains cannot be taken to keep it free from weeds. Winter barley, and rye, which are reaped early in July, are very proper crops to be succeeded by rape or colza. The stubble should be ploughed two or three times, to pulverise and clean it. A good coat of rotten dung should be put on, and the land ploughed in ridges, as for turnips: the plants should be put in on the ridges ten inches apart. It requires great care in taking them up not to break the fibres of the roots: they should be raised with a fork, and placed gently, with the fine earth adhering to them, in flat baskets, and in a slanting position, so that the tops may be upwards. In planting, the holes should be made with a large thick dibble, that the plants may be introduced without doubling up the principal roots or breaking the fibres. The earth should be pressed to the root by a short dibble, inserted to the right or left of the hole made by the first dibble; or, which is better in stiff soils, a hole should be made with a narrow hoe of sufficient depth to allow the plant to be placed in it, and another hoe should follow to draw the earth to the plant. Thus two men with hoes, and one woman, will plant a row more rapidly than could be done any other way: the man who fills up the holes places his foot by the side of each plant as he goes on, to press the earth to the roots.

An expeditious mode of planting rape is used in Flanders. A spade ten inches wide is pushed vertically into the ground, and, by drawing the handle towards his body, the labourer makes a wedge-like opening; a woman inserts a plant in each side in this opening, and when the man removes the spade, the earth falls back against the plants. The woman puts her foot between the two plants, and they are then fixed in their places. In this operation the man moves backwards; and the woman, who puts in the plants, forward. Instead of the spade, an instrument is also used called a *plantoir*. It consists of two sharp-pointed stakes a foot or more apart, connected by a cross-handle at top, and a bar at about eight or ten inches from the points. The instrument is pressed into the ground by the handles, assisted by the foot placed on the lower bar, and makes two holes, a foot apart, into which the plants are placed, and earthed round as before. This is done when the land has not been laid up into high ridges.

When a large field is to be planted, a more expeditious mode is adopted; and this is the most usual practice in Holland and Germany. The land having been prepared, and the manure well incorporated, a deep furrow is drawn with the plough; women follow with baskets of plants, which they set, a foot apart, slanting against the furrow slice. When the plough returns, the earth is thrown against these plants; and a man or woman follows, who, with the foot, presses the earth down upon the roots. Sometimes plants are put into each furrow, which is then ten inches or more wide; but the best cultivators put them only in every alternate furrow. In this case also there are no ridges. The season of the year affords sufficient moisture in the north of Europe to ensure the growth of the plants; and if they have escaped the fly in the seed-bed, they are now tolerably safe. No further attention is requisite till spring. The weeds are then carefully extirpated by hand and hoe: and where the distance of the plants admits of it, the light plough stirs the ground between the rows, throwing the earth towards the stems; yet so as to leave each plant in a little basin to catch the water and conduct it to the roots. When the plants are invigorated with rich liquid manure, such as night-soil mixed with water, or the drainings from dunghills, they become extremely luxuriant; and every trouble or expense bestowed upon them is amply repaid. The difference between a crop partially neglected and another carefully cultivated often exceeds fifty per cent.

A moderate return of seed for colza is thirty bushels per acre, but it frequently exceeds fifty. The value on the Continent is nearly the same as that of wheat. In England it is somewhat less, owing to the quantity imported, on which there is a fixed duty of 10*s*. per quarter. It is usually sold by the last of ten quarters.

There is not much difference between the value of colza and rape-seed (called *navette* in French): but the latter produces less. When the rape is transplanted before winter, it is much more productive than when sown in spring. In the latter case it produces seed the same year. It is sown in drills, and thinned out by the hoe, and in favourable seasons a tolerable crop is obtained. It is generally sown on land which could not be brought into a proper tilth after harvest, and which would require the frost of winter to mellow it.

Great crops of cole-seed and rape have been produced in the fens of Lincolnshire and the alluvial soils in Essex, by merely paring and burning the surface and ploughing in the ashes; and these crops, alternating with oats, have in many instances so exhausted the soil as to cause a great prejudice against them in the minds of the landlords. Many leases have a clause prohibiting its cultivation, except to be eaten green by sheep. The principal cause however of the diminution of this crop in England is the inferior price obtained for the seed when compared with wheat, which can be raised on the same land, and is a more certain crop.

The rape and colza ripen their seed very unequally. The lower pods are ready to burst before those at top are full. If the season is wet at harvest, much of the seed is lost; and, without great attention, some loss is sustained in the most favourable seasons. It should be cut when the dew is on it, and moved as little as possible. If the weather permits, it is threshed out on a cloth in the field, and as many threshers are employed as can be conveniently collected, that no time may be lost, when the weather is fair. The seed is spread out on the floor of a granary that it may not heat, and is turned over frequently. It is then sold to the crushers, who express the oil. The pods and small branches broken off in threshing are much relished by cattle. This crop returns little to the land, and is of itself very exhausting. Not so however is the rape, when sown as food for sheep. It is, on the contrary, a valuable substitute for turnips, upon land which is too wet and heavy for this root. The Brassica oleracea is more succulent than the Brassica napus. Its stem is not so hard, and the soft pith which it contains is much relished by every kind of live-stock. To have it in perfection, the land should be prepared and manured as for turnips. The rape should be sown in drills ten inches apart, about the beginning or middle of August, which gives ample time for preparing the land, without interfering with the turnip crop. It will be sufficiently forward before winter, and it should then be hoed over once. If the crop is very forward, it may be slightly fed off: but, in general, it is best to let it remain untouched till spring. In the end of March and beginning of April it will be a great help to the ewes and lambs. It will produce excellent food till it begins to be in flower, when it should immediately be ploughed up. The ground will be found greatly recruited by the crop, which has taken nothing from it and has added much by the dung and urine of the sheep. Whatever be the succeeding crop, it cannot fail to be productive; and if the land is not clean, the farmer must have neglected the double opportunity of destroying weeds in the preceding summer and in the early part of spring. If the rape is fed off in time, it may be succeeded by barley or oats with clover or grass seeds, or potatoes, if the soil is not too wet. Thus, no crop will be lost, and the rape will have been a clear addition to the produce of the land. Any crop which is taken off the land in a green state, especially if it be fed off with sheep, may be repeated, without risk of failure, provided the land be properly tilled; but where cole or rape have produced seed, they cannot be profitably sown in less than five or six years after on the same land.

When the oil has been pressed out from the seed, the residue (which contains a portion of starch and mucilage not changed into oil) and the husk of the seed form a hard cake known by the name of rape cake. This is used on the Continent to feed cows and pigs with, as we use the linseed cakes: but it is also much used as a rich manure, and for this purpose it is imported in large quantities. When rape cake is ground to a powder and drilled with the seed on poor light lands, it supplies nourishment to the young plants, and greatly accelerates their growth; but if it be added in a large proportion in immediate contact with the seed, in heavy impervious soils, it often undergoes the putrid fermentation, which it communicates to the seed sown, and, instead of nourishing, destroys it. In this case it is useful to mix it with some dry porous earth or with ashes, which will prevent the too rapid decomposition. Dissolved in water and mixed with urine, it forms one of the most efficacious of artificial liquid manures. Hence it is probable that the most advantageous mode of using it on the land, after it has been dissolved in the urine-tank, is to apply it by means of a water-cart to the rows where the seed has been already drilled, or some time before it is put in. Where flax is to be sown, this mixture applied a few days before the seed is sown, so as to allow it to sink into the soil, is considered in Flanders as next in value to the emptyings of privies, which with them hold the first rank, for producing fine crops of flax. When a crop appears sickly, and not growing as it should do, owing to poverty in the soil, a top-dressing of rape-cake dissolved in water, if no urine is at hand, will in general excite the powers of vegetation; and it is highly probable that it may greatly assist the effects of saltpetre or of nitrate of soda, where these salts are applied. The cultivation of rape or cole for spring food cannot be too strongly recommended to the farmers of heavy clay soils.

RAPHAEL, or RAFFAELLO SANZIO, was born at Urbino, on Good Friday, March 28, 1483. He was the son of Giovanni de' Santi, a painter of merit in that city, some of whose works still exist. A specimen of them may be seen in the Berlin Gallery (No. 215, first division), bearing the name of Giovanni, and showing considerable beauty, but with weak colouring. Although Raphael lost his parents before he was twelve years old, he imbibed the rudiments of art from his father. Other artists of that peculiar school which fixed itself in Umbria, such as Nicolo Alunno of Foligno, and Andrea Luigi of Assisi, probably exercised some influence over the young painter. At what age he became the pupil of Perugino we know not, but traces of the scholar's hand are supposed to be visible in several of the works of the master; among others in the frescoes of the Cambio at Perugia, which where painted about the year 1500.

The career of Raphael is usually divided into three periods, of which the first terminates with his visit to Florence, in the autumn of 1504; the second comprises the time from that date until he was invited to Rome by Julius II., about the middle of 1508; and the third extends to his death, in 1520.

1. To begin with the works executed before Raphael's visit to Florence. One of the earliest of these now extant is probably the Virgin with the Book, in the Berlin Gallery (No. 223, first division), and a still more important picture of this period is the Adoration of the Magi, in the same collection (223 a). The latter is executed on linen, in size colours ('*al guazzo*'), and was originally intended for the high altar at Ferentillo; it was purchased by the late king of Prussia, from the Ancajani family at Spoleto, for the sum of 6000 scudi, and has suffered a good deal from the peeling of some of the colours.

The pictures painted at Citta di Castello were, the Coronation of St. Nicholas of Tolentino (said to have disappeared from the Vatican during the French occupation); the Sposalizio, or Marriage of the Virgin (now in the Brera at Milan), and the Christ on the Cross, in the collection of Cardinal Fesch. Lanzi, on the authority of mere tradition, states that the first of these three was painted when Raphael was only seventeen, that is, in 1500, and he assigns the last to about the same time. Both probably approach very nearly in time to the Sposalizio, which bears the date of 1504. The Coronation of the Virgin (now in the Vatican) clearly shows the struggle of new principles, although Vasari, whose contempt for the simplicity of the earlier style led him to content himself with very general resemblances, refers to this picture as one of those which prove how closely Raphael imitated the manner of Perugino. Notwithstanding Vasari's assertion to the contrary, it seems probable that both the Coronation of the Virgin and the Crucifixion belonging to Cardinal Fesch were posterior to the Sposalizio.

Raphael's share in the frescoes executed by Pinturicchio, in the Libreria of the Cathedral at Siena, has been much exaggerated. There is little doubt that he never worked there in person, although he furnished some drawings to his fellow-pupil; two of these are yet extant, one in the Florence Gallery, and the other in the Baldeschi collection at Perugia. Vasari's whole account of Raphael's first visit to Florence is confused in the highest degree. He describes him as induced to quit Siena by the report of Leonardo's Battle of the Standard and of M. Angelo's Cartoon, although the latter work was not exhibited till 1506, while the frescoes of Pinturicchio were probably completed in 1503, and the date of Raphael's journey is fixed to October, 1504, by the letter of recommendation for the Gonfaloniere Soderini from the duchess of Sora. Quatremère de Quincy tries to solve the difficulty by assuming a visit to Florence in 1503, and another in the following year, but a strong presumption against this supposition is furnished by the total absence of all trace of Florentine principles in the Marriage of the Virgin. Susceptible of new impressions in art as Raphael afterwards showed himself, it is impossible that the first introduction to his great Florentine contemporaries should have left no trace in his works. Now the pictures of 1505 exhibit clear traces of a new influence. In fact, at the time of his arrival at Florence, art had just reached the point which enabled him to reap the fullest benefit from the new field thus thrown open. He studied the works of Masaccio, and became the friend of Fra Bartolomeo and Ridolfo Ghirlandaio. [PAINTING.] In the following year we find him employed again at Perugia. The fresco in San Severo, and the altar-piece for the Ansidei family (now at Blenheim) were painted in 1505. Whether the picture executed for the nuns of St. Antonio of Padua at Perugia, which is at Naples, be of the same or of a later date, is a disputed point. The separate portions of the 'Predella,' or step belonging to the latter picture, are in England, in the respective collections of Mr. Rogers, Mr. Miles of Leigh Court, and Mr. White of Baron Hill.

Four pictures of the Virgin and Child of Raphael's Florentine period are distinguished by different characters, though all exquisitely beautiful. The Madonna del Gran Duca, in the Pitti palace, is the most simple, and, to our judgment, the most admirable of them all. It still breathes much of the spirit of the Umbrian school. The other three are the Madonna Tempi at Munich, the Colonna Madonna at Berlin, and the picture in the possession of Lord Cowper at Panshanger. To the same time must be attributed the Madonna del Cardellino, in the Tribune at Florence, the Belle Jardinière at Paris, and the Holy Family with the Palm, in the Bridgewater collection. The first of these three was painted for Lorenzo Nasi. Raphael's power and fidelity as a portrait painter are well shown in the beautiful portraits of Angelo and Maddalena Doni, in the Pitti palace, and in two heads of monks, in the Academia at Florence. The St. Catherine, which passed from the Aldobrandini collection into that of Mr. Beckford, and still more lately into the National Gallery, was executed in the latter part of the artist's residence at Florence. The two works which must be considered as closing this division are the Madonna del Baldacchino, or di Pescia, left unfinished when the painter started for Rome, and the Entombment of Christ. The former picture bears some resemblance in its technical details to the works of Fra Bartolomeo; it is now in the Pitti palace. The latter was painted by order of Atalanta Baglioni, for S. Francesco at Perugia, and forms part of the Borghese collection. It is an elaborate composition, of the greatest beauty and power of expression, proving how much Raphael had profited by his Florentine studies. The figures from the Predella are in the Vatican.

The invitation given by Julius II. to Raphael would be sufficiently accounted for by the celebrity of the artist himself, although it is very probable that his connection with the family Della Rovere, or the favour of his fellow-countryman Bramante, facilitated his introduction at the papal court. He seems to have left Florence, rather suddenly, towards the end of the year 1508.

The 'Stanze' decorated by the pencil of Raphael were the living-rooms of the papal court in the time of Leo X. His frescoes suffered during the occupation of Rome by the imperial troops, in 1527, and by subsequent neglect, when the popes had transferred their residence to the Quirinal. In the years 1702 and 1703 they were cleaned and restored, by Carlo Maratti, who re-painted the larger portion of the decorative framework.

The Camera della Segnatura was the first worked on by Raphael. The figures of Theology, Poetry, Philosophy, and Justice on the ceiling preceded in execution the large paintings on the walls. Of these last the Disputa del Sacramento, as it is commonly called, was the earliest. In simple beauty and severe dignity, in energy and individual character, this work has never been surpassed; in technical excellence, and the picturesque qualities of breadth, composition, and softness, it is certainly inferior to the Parnassus and the School of Athens, which came next. The allegorical figures of Temperance, Fortitude, and Prudence, in the semicircular division on the remaining side of the room, are among the most beautiful of Raphael's designs.

In the Stanza d'Eliodoro, the fresco of Heliodorus, together with that of the Mass of Bolsena and the scripture subjects in the ceiling were executed in the pontificate of Julius. It is impossible to show more complete understanding of the application of painting to a story than Raphael has displayed in the first of these compositions. The colouring of the Mass of Bolsena is admirable.

In 1513 Leo X. succeeded to the papal chair. The two remaining frescoes in the Stanza d'Eliodoro, that is to say, Attila repelled from Rome, and the Liberation of St. Peter, belong to his reign. The latter is supposed to allude to the pope's escape, when Cardinal de' Medici, after the battle of Ravenna, and the former to the retreat of the French from Italy.

In the third room, or Stanza del Incendio, the ceiling contains some paintings of P. Perugino, which were spared when those of other masters were destroyed to make room for the works of Raphael. The subjects on the walls are the Burning of the Borgo, or suburb of Rome, the Victory over the Saracens at Ostia, the Coronation of Charlemagne, and the Death of Leo III. The execution of all these was more or less left to pupils; those in the Sala di Costantino were wholly painted by Julio Romano and others, from designs by Raphael.

The loggie, or open colonnades, designed by Bramante, were decorated under the directions of Raphael by his principal scholars. The Cartoons for the tapestry to be hung round the Sistine Chapel were prepared in 1515 and 1516, at the desire of Leo X. These cartoons were cut into strips for the convenience of the workmen at Arras. By some unaccountable neglect they remained in Flanders, and seven of the ten were, after the expiration of a century, bought by Charles I. at the suggestion of Rubens. When the property of the crown was sold by the Commonwealth, they were valued at 300*l.*, and purchased by Cromwell's order at that price for the nation. William III. caused these precious fragments to be properly mounted and put up at Hampton Court. In 1766 they were removed to Buckingham House; thence carried to Windsor; and in 1804 again restored to Hampton Court. The Cartoons have far greater pretensions to be considered as original works of Raphael than the paintings in the two last rooms of the Vatican just referred to. In composition they are unrivalled, and their whole conception is admirably adapted to the purpose which they were meant to fulfil. [CARTOONS.]

The Isaiah in San Agostino was probably painted in 1512 or 1513; and the Sibyls in Santa Maria della Pace shortly afterwards. Rumohr, on technical grounds, places the latter (one of the artist's most admirable works) about 1515. Their subjects and their mode of treatment sufficiently establish in a general sense that imitation of Michael Angelo of which so much has been said.

We must now return to the smaller works of Raphael.

Vasari says that his portrait of Julius II. was so like as to inspire fear, as if it were alive. The original thus spoken of is supposed to be in the tribune at Florence. Two copies of it are in the Pitti Palace, and one in our own National Gallery. The last came from the Borghese collection. On the subject of Raphael's own portrait a good deal of controversy has taken place. It is certainly difficult to detect much resemblance between the portrait in the Florence collection and that purchased by the king of Bavaria from the Altoviti family; and the expression of Vasari, 'à Bindo Altoviti fece il ritratto suo,' is ambiguous, but nevertheless we believe the picture now at Munich to be the work of Raphael, and his own portrait. Missirini and the Italians would probably have discussed the question with much less angry zeal if the picture had not been transferred to a foreign country.

Three portraits exist, which are believed to represent Raphael's mistress, the so-called Fornarina, painted by himself. One of these is in the Barberini, another in the Sciarra palace (at Rome), and the third is in the Tribune at Florence. This last picture bears the date of 1512, and was at one time attributed to Giorgione. Certain it is that the colour would be worthy of the Venetian master, and that the face and form are Venetian in their character.

The Madonna della Seggiola, the Madonna del Duca di Alba, and several others of somewhat similar feeling belong to the early part of Raphael's residence at Rome. The Madonna di Foligno, now in the Vatican, was painted for Gismondo Conti, probably about the time of the completion of the Camera della Segnatura. The Vision of Ezekiel is said to have been paid for in 1510; two pictures of the subject exist, one in the Pitti palace, and another, from the Orleans gallery, in the collection of Sir Thomas Baring. It is disputed whether either, and if either, which of these two is the original. Dr. Waagen prefers the claims of the Florence picture. The St. Cecilia at Bologna was ordered about 1510, and completed somewhat later; it has suffered greatly from restoration.

The four great altar-pieces of Raphael's later time are—

1. The Madonna del Pez, painted for San Domenico at Naples, and now (1833) in the Iglesia Vieja of the Escurial. It is a composition of the purest and simplest beauty.

2. The Madonna di S. Sisto, the well known pride of the Dresden gallery. This picture has had the good fortune to be engraved better than any other in the world. It is painted on canvas, and Rumohr conjectures that it was intended for a 'drapellone,' or large standard, to be carried in procession, attached to two poles. A picture, by Guido, painted on grey silk, and called 'il pallione,' from being used in this manner, is to be seen in the Pinacoteca at Bologna (No. 138). The most striking points in the Madonna di S. Sisto are the deeply meditative anticipation of future suffering in the Virgin, and the superhuman character imparted to the Christ by the union of a childish form with the severe thoughtfulness of maturer age.

3. The Spasimo di Sicilia, executed for Santa Maria dello Spasimo, at Palermo, is now in the public gallery at Madrid. There is something academical in the figure of the executioner, but the deep feeling in the right-hand group of women reminds us of the Borghese entombment. This picture has suffered much by restoration, and has acquired a sort of brickdust colour.

4. The Transfiguration, usually considered to be Raphael's masterpiece. It was left unfinished at his death.

Besides the above-named works, we must allude to the Visitation and the Perla, both in the Sacristy of the Escurial. The latter formed part of the collection of Charles I of England.

The Archangel Michael, and the Holy Family, painted in 1518, for Francis I., are first-rate pictures of the artist's later time. In the portrait of Leo X., with the Cardinals de' Medici and Rossi (painted not earlier than 1518), Raphael has shown that he could rival the Flemish masters in the accurate imitation of ordinary household objects. The Violin-Player, in the Sciarra palace at Rome, also bears the date of 1518. The portraits of Joanna of Aragon, Baltasar Castiglione, and others, we have not space to dwell on.

Raphael occupied himself with architecture as well as painting, and seems to have felt a zealous interest in all remains of antient art. The Psyche and the Galatea, executed in the Farnesina at Rome for Alessandro Chigi, are his principal works which represent mythological subjects.

On the 6th of April, 1520, being Good Friday, this greatest of all modern painters died of an attack of fever, at the age of thirty-seven.

All that is recorded of his public and private character represents him as most amiable, and as the object of sincere affection on the part of his immediate friends. As an artist he was especially distinguished in two things. In the first place, whatever was the principle of art which he adopted at different periods of his life, in each and all successively he attained the greatest excellence. In his early pictures the spirit of Perugino and of the Umbrian school beamed with double purity and beauty; but his powers were not limited within the narrow circle which hemmed in his master and caused him to reproduce the same forms and the same expression through the course of a long life. Raphael came to Florence at a fortunate moment. The anatomical studies of Leonardo and M. Angelo, and the powers of Masaccio, had exactly provided the fresh food for which his genius was craving. The religious feeling of his earlier works became a little unspiritualised in the worldly city of Florence, but his technical power received a great accession of strength, while his capacity for seizing real life is sufficiently shown by the portrait of Maddalena Doni. His Madonnas at this time lose something of their thoughtful melancholy, and often acquire a smiling character, such as we find in the works of Leonardo. Still his pictures exhibit excellence peculiar to himself.

In his third period, many persons, like Monsieur Rio (*L'Art Chrétien*), may consider the 'Disputa' as the last gleam of primitive simplicity or beauty. It may be said that thenceforth the Christian painter became paganised by contact with the heathen courts of Julius II. and Leo. X. It is true that at this particular time a change took place in the style of art adopted by Raphael. He had acquired a new sense for the effect of masses in his drapery and in his lights and shades, and he worked on principles more consonant with the modern notions of picturesque composition. Which of the two sources of pleasure from painting is the purest and the most genuine may be a subject of dispute, but there can be no dispute as to the fact that in each line, as he successively adopted them, Raphael attained the highest pitch of excellence of which they respectively admitted. We cannot however allow that an artist who could execute the Cartoons had lost the power of conceiving and worthily embodying Christian subjects.

The second consideration which seems to place Raphael before all other painters is the fact that of the large number of works attributed to him with any certainty, hardly one can be called ordinary or commonplace in its character. If we consider the early age at which he died, his pictures are very numerous. The best of them are confessedly superior to the finest productions of other masters, and their average quality is in a still greater degree superior to the average quality of the works of any other painter.

(Vasari, *Vita dei Pittori*, vol. iii.; Lanzi, *Storia Pittorica;* Quatremère de Quincy, *Vita di Raffaello, tradotta da Longhena;* Rumohr, *Italienische Forschungen*, vol. iii.; Bunsen, &c., *Beschreibung der Stadt Rom.*, vol. ii.; Waagen, *Kunstwerke und Künstler in England und Paris;* Passavant, *Rafael von Urbino; Quarterly Review*, No. cxxxi.; Rio, *L'Art Chrétien.*)

RA'PHANUS, a Brassicaceous or Cruciferous genus of plants, is only remarkable for containing the common radish, Raphanus sativus. This plant, a native of China, has been cultivated in this country for upwards of 250 years, and has given rise to numerous varieties, which are divided into long-rooted or spindle-shaped, and round or turnip-rooted. They are also denominated spring, summer, autumn, or winter radishes, according to the season in which the respective sorts are found best adapted for use.

The *Scarlet* or *Salmon-coloured*, and the *Radis rose demi-longue*, are the best for early sowing; the latter variety is very tender and of a fine bright colour. The purple, another early long-rooted variety, is sometimes sold under the name of *Salad Radish*, the seed-leaves being larger and consequently better adapted for small salading than those of the other varieties. With the colour of the preceding sorts, the *Long White Transparent* will form an agreeable contrast. Of the round or turnip-rooted varieties, the *Early White Turnip-rooted* and the *Purple Turnip-rooted* are the best. The *Yellow Radish* succeeds in hot weather, being fit for use when the earlier kinds are apt to run to seed; and it precedes the autumn and winter varieties, of which the following is the order of succession: *Round Brown, White Spanish, Oblong Brown, Black Spanish*, and *Purple Spanish*. None of these are however esteemed in this country, where they are generally unknown.

If the early white turnip-radish be sown in August, it will come into use in autumn. The principal sowings should however be made in January and February, and successionally till May. The winter varieties require to be sown in July. In cold frosty weather the beds should be protected by straw, as is commonly practised, or by such other efficient means as may be at command. The covering should be always dispensed with when the days are fine; but it ought to be replaced before the cold of night ensues. Radish seed-pods are sometimes pickled, whilst tender, and may be used instead of capers, when the latter cannot be obtained.

RAPHOE, a city in Ireland, in the parish and barony of Raphoe, in the county of Donegal in Ulster, 145 miles north-west of Dublin, through Drogheda, Monaghan, Omagh, and Lifford. The parish comprehends 34,356 statute acres, chiefly land of good quality. The population, in 1831, was 1408 for the town, and 4819 for the rest of the parish; making a total of 6227, chiefly agricultural. The town (which derived its early importance from a monastery, founded, it is said, by St. Columb, and afterwards made the seat of a bishopric) consists of three small streets meeting in the market-place. There is a neat market-house. The cathedral is also the parish church; it is a plain cruciform building, with a square tower, which was added about a century ago. The date of the erection of the church is not known. There is a handsome and spacious episcopal palace at a short distance from the town. The Presbyterians have a meeting-house in the parish.

There is a market on Saturday for provisions and occasionally a little linen-yarn: the markets on the first Saturdays in January, February, March, April, and December, are great markets: there are several yearly fairs. There are petty-sessions every fortnight, and a body of the county police are stationed here.

The population, in 1834, comprehended 1149 persons belonging to the Establishment, 2730 Catholics, and 2552 Presbyterians. The congregations at the church and the Presbyterian meeting-house were increasing. The benefice is a rectory, the average gross yearly income of which for the three years ending with December, 1831, was 1050*l.*, exclusive of fines on the renewal of leases the glebe, the value of which is included in the above return, comprehends about 209 or 210 statute acres · the average net income was 771*l.* · the living constitutes the corps of the deanery of Raphoe.

There were in the parish, in 1835, ten day-schools, with a total of 505 scholars, viz. 332 males and 173 females; and four Sunday-schools. Among the day-schools were a royal endowed school with 27 boys, a national school with 70 boys and girls, and four hedge-schools.

RAPHOE, DIOCESE OF, one of the bishoprics of the ecclesiastical province of Armagh. It is bounded on the north and west by the Atlantic, on the east by the diocese of Derry, from which it is separated in one part by Lough Swilly, and in another part by the river Foyle; and on the south by the diocese of Clogher. It comprehends part of the county of Donegal. The dimensions of the diocese, as given by Dr. Beaufort, are 44 Irish or 56 English miles in length, and 32 Irish or 40 English miles in breadth; the area at 515,250 acres Irish, or 827,779 acres (1293 square miles) English measure.

The time when the diocese was established is unknown. Bishops of Raphoe are mentioned in the ninth century. The cathedral has been already described. [RAPHOE.] The chapter consists of the dean, the archdeacon, and four prebendaries. The gross revenue of the bishopric for the three years ending with December, 1831, was 5787*l.* 8*s.* 2*d.*; the net revenue, 5052*l.* 11*s.* 2*d.* The bishop presents to one of the dignities, three of the prebends, and twelve other benefices.

In 1792 the number of parishes was stated by Dr. Beaufort to be 31, of benefices 25, of churches 32, and of glebe-houses 17. By the Returns made to parliament in 1835 by the Commissioners of Public Instruction (*Parl. Papers* for 1835, vol. xxiii.), the number of benefices was 34, two of them unions of two or more parishes; the number of churches 34, and of other places of worship of the Establishment 7. The diocese was estimated to contain 33,507 members of the Established Church, 145,385 Roman Catholics, 28,914 Presbyterians, and 24 other Protestant Dissenters. There were 36 Catholic chapels, 27 Presbyterian meeting-houses, and 14 other places of worship not of the Establishment, chiefly belonging to the Methodists, who, in the account of the population, are classed among the members of the Established Church.

By the Returns of the same Commissioners (*Parl. Papers for* 1835, vol. xxiv.) there appear to have been in the diocese 263 day-schools, with about 14,500 scholars: of these schools 127 were wholly supported by the payments of the children, and 136 were wholly or partly supported by endowment or subscription. Only four were in connection with the National Board. The number of children under instruction was 6·98 per cent. of the whole population; this was considerably under the average of the dioceses of the province of Armagh, and also below the average of all Ireland.

This diocese has, by virtue of the Act 3 and 4 Will. IV., c. 37, been united to the diocese of Derry. In the Roman Catholic division of Ireland, the diocese is co-extensive with that of the Established Church. The cathedral and the bishop's residence are at Letterkenny, not far from Raphoe.

RAPHUS, Brisson's name for the Dodo. [DODO.]

RAPI'N, PAUL DE, a younger son of Jacques de Rapin, Sieur of Thoyras, was born at Castres, in 1661, of a Protestant family which came originally from Savoy. He studied in the Protestant College of Saumur, and afterwards entered the profession of the law. But the revocation of the Edict of Nantes by Louis XIV., in 1686, drove him from his native country, and he went first to England and afterwards to Holland, where he entered the service of William of Nassau as a volunteer. He accompanied William to England in 1688, was made an officer in an English regiment, served in Ireland under General Douglas, and was wounded at Limerick. Not long after, he was appointed travelling tutor to the young duke of Portland, with whom he spent several years. Having completed his engagement, he retired with his wife first to the Hague, and afterwards, for the sake of economy, to Wesel, where he commenced his great work, the 'History of England,' which occupied him for seventeen years. The application requisite for this undertaking is said to have exhausted his frame, and he died at Wesel in 1725. His work is entitled

'Histoire d'Angleterre depuis l'Etablissement des Romains jusqu' à la Mort de Charles I.,' 8 vols. 4to., La Haye, 1724, and foll. It was continued by others down to the accession of George II. The work was translated into English by Nicholas Tindal. This translation went through various editions; that of 1757 9 consists of 21 vols. 8vo., and is enriched with additional notes and a biography of Rapin. Rapin writes with spirit and ease; he quotes his authorities; and his work was the only complete history of England existing at the time of its appearance. Some French critics have accused him of partiality and of being unjustly severe upon his native country, which they attribute to the impression produced upon him by the persecution of his fellow-Protestants by Louis XIV. But this is a vague assertion, unless substantiated by facts. Rapin wrote also a 'Dissertation sur les Whigs et les Torys.'

RAPTATO'RES, Illiger's name for his third order of birds, comprehending the *Birds of Prey*.

His *Raptatores* consist of the following families and genera:—

Nocturni.—*Strix*.

Accipitrini.—*Falco, Gypogeranus, Gypäetus*.

Vulturini.—*Vultur, Cathartes*.

This order is placed by Illiger between the *Ambulatores* and *Rasores*.

The *Accipitres*, Linné's first order, include the genera *Vultur, Falco, Strix*, and *Lanius*.

RAPTO'RES, the name assigned by Mr. Vigors to the *Birds of Prey*. [RAPTATORES.]

The *Raptores* of Mr. Vigors form his first order, and the following families are arranged by him under it:—VULTURIDÆ, FALCONIDÆ, STRIGIDÆ, *Gypogeranidæ?*

The *Raptores* of Mr. Swainson comprise the families of *Vulturidæ, Falconidæ*, and *Strigidæ*.

Mr. G. R. Gray also makes the *Raptores* consist of the families *Vulturidæ, Falconidæ*, and *Strigidæ*.

RAREFACTION is an augmentation of the intervals between the particles of aeriform fluids, so that the same number of particles are made to occupy a volume greater than that under which they were previously contained. The term is used in opposition to condensation, and in the same sense as dilatation, which last is applied both to fluids and solids. Rarefaction or dilatation is caused by a repulsive power existing either in the particles of bodies or in those of the caloric between them, by which power the particles are made to recede from one another when not prevented by some external resistance.

The experiments of Lavoisier and Laplace have shown that, between the temperatures of freezing and of boiling water, the dilatations of all metals and of the fluids called non-elastic are constantly proportional to the increments of temperature; but beyond the temperature of boiling water, the experiments of Dulong and Petit indicate that the dilatations increase in a higher ratio. A remarkable circumstance is observed in the state of water when near congelation. On being cooled to a temperature within the limits of 33·9° and 34·5° (Fahrenheit), its volume remains stationary, and in this state water seems to have attained its maximum of density; for, on continuing the cooling process, the water begins to expand, and it continues to do so until it is converted into ice.

From the experiments of M. Gay-Lussac and Dr. Dalton it has been ascertained that, under equal external pressures, the rarefactions of all dry gases and of the aeriform substances produced by the evaporation of liquids are equal at equal temperatures, between the points of freezing and boiling water, and that they vary in volume proportionally to the increments of heat expressed by the expansions of mercury in the thermometer. [HEAT, p. 89, col. 1; GAS, p. 81, col. 1; and PNEUMATICS, p. 295, col. 1.]

The density or closeness of the aerial particles in any given portion of the atmosphere depends on the pressure or weight of the column of air above the given point; and by the law of Boyle or Mariotte, whatever be the temperature, provided it be constant, the density is proportional to the pressure; or, conversely, the rarefaction is inversely proportional to the pressure. It has been proved [PNEUMATICS] that the densities of the strata of air decrease upwards in a geometrical progression when the altitudes of the strata increase by equal increments; and this is equivalent to saying that the rarefactions of the air at such altitudes increase in a geometrical progression. Now if A be any point on the surface of the earth, and C any point above it, the formula

$$\text{AC (in fathoms)} = 10670 \times \log.\frac{\textit{density at A}}{\textit{density at C}} \text{ [PNEUMATICS]}$$

will afford the means of computing the rarefaction of the air at any point C, when its height above A is given. But if the density at A be considered as unity (the temperature being = 55°) the equation may be transformed into

$$\frac{\text{AC}}{10670}\left(= \log.\frac{1}{\textit{density at C}}\right) = \log.\ \textit{rarefaction at C},$$

in which, substituting for AC any given value in fathoms, the rarefaction may be found. For example, let AC = 3212 fathoms (= 3·65 miles); then the second member of the equation will become ·30103 (= log. 2), which shows that at the height of about 3¾ miles the rarefaction of the atmosphere is twice as great as at the surface of the earth; and by forming the progression of heights—

0 , 3·65 , 7·3 , 14·6, &c. in miles,

we have for the corresponding rarefactions—

1 , 2 , 4 , 8, &c.

A formula for the rarefaction of the air in an air-pump, after any number of strokes of the piston, is given near the end of the article PNEUMATICS.

The limits to which rarefaction may be carried are unknown, but the experiments of Mr. Boyle and others have proved that, by simply removing the external pressure, air may be so rarified that a given volume of the same density as at the surface of the earth will occupy a volume more than 13,000 times as great. It has been however discovered that at very high degrees of rarefaction the elasticity of the air decreases in a higher ratio than the density; and this may serve to prove that rarefaction cannot take place to an infinite extent.

RASAN. [RIASAN.]

RASA'RIUS, or, more properly, **GIAMBATISTA RASARIO**, an Italian physician, was born of a noble family, in 1517, in the province of Novara, in the Sardinian territories. After having studied at Milan and Pavia, he took the degree of doctor of medicine at the university of Padua. Upon his return to Milan, his learning soon gained him so great a reputation, that the republic of Venice invited him to their city, where he was professor of rhetoric and the Greek language for two and twenty years. Here he distinguished himself by his eloquence, particularly on occasion of the battle of Lepanto, 1571, when, at the command of the doge, and with a very short time for preparation, he pronounced in the church of St. Mark a public oration that has been several times printed. (See vol. iii., *Orat. de Bello Turcico per Nic. Reusnerum*, Lips., 4to. 1596.) He afterwards went to Rome, where the pope, Pius IV., made him the offer of some good appointments, which however he thought fit to decline, as he did not like a residence in that city. He chose rather to accept the office of professor of rhetoric at Pavia, where he died about four years after, in 1578, at the age of sixty-one. His works consisted principally of editions and translations of various Greek writers, such as:—'Galeni Comment. in Hippocr. libr. ii. et vi. Morb. Popular., De Alimentis, et De Humoribus,' Cæsaraugustæ (Saragossa), 1567, 4to.; 'Oribasii quæ restant Omnia, Tribus Tomis digesta,' Basil., 1557, 8vo.; 'Georgii Pachymeris Epitome Logicæ Aristotelis,' Paris, 1547, 8vo; 'G. Pachym. in Univ. Aristot. Disserendi Artem Epitome,' with 'Ammonius in Porphyr. Inst.,' Lugd., 1547, fol.; 'Xenocrates de Alimento ex Aquatilibus,' in Fabricii 'Bibl. Gr.,' tom. ix., pp. 454-474; 'Joannis Grammatici (sive Philoponi), Comment. in primos iv. Aristot. de Naturali Auscult. Libros,' Venet., 1558, fol.

RASIS, or rather **AR-RA'ZI'**, is the patronymic of a celebrated Arabian writer, whose entire name was Ahmed Ibn Mohammed Ibn Músa. He was denominated Ar-razí because his family was from Ray, a province of Persia. He was born at Cordova, about the middle of the third century of the Hejira (A.D. 864-70). His father Mohammed Ibn Músa, who was a native of Persia and a wealthy merchant, was in the habit of travelling yearly to Spain with drugs and other produce of the East. Being a man of some learning and ability, he met with great favour and protection from the sultans of the house of Merwan, who then reigned in Cordova, and in one of his visits was prevailed upon to settle in that capital, where he filled offices of trust, being employed in various embassies. He died in the month of Rabi-l-akhar, A.H. 273 (October, A.D. 886). His son Ahmed, when still young, wrote some poems, which he dedicated to Abdu-r-rahman III., sultan of Cordova. He also distinguished himself by his early acquirements in theology and jurisprudence, on which sciences he is said to have left several excellent treatises. But it is in his capacity of royal historiographer that Ar rází gained most renown. Besides many historical works, the titles of which have not reached us, he wrote a very voluminous history of the conquest of Spain by the Arabs, together with a geographical description of that country, and a few interesting details on its natural productions, industry, commerce, &c. He wrote likewise a history of Mohammedan Spain under the dynasty of the Beni-Umeyyah [MOORS]; and a topographical description of Cordova, the seat of their empire. There is also a genealogical history by him of all the Arabian tribes who settled in Spain at the time of the conquest or soon after it. A portion of the first-mentioned historical work was translated into Spanish, about the end of the thirteenth century, by a converted Moor, named Mohammed, and by Gil Perez, a chaplain to King Dinis of Portugal, by whose orders the version was made. Both Casiri (*Bib. Ar. Hisp. Esc.*, vol. ii., p. 329) and Conde (*Hist. de la Dom.*, vol. i., p. 9) have asserted, without the least foundation, that the 'Historia del Moro Rasis'—for such is the title of the Spanish version—is apocryphal, but there can be no doubt that the work, though containing numerous interpolations, and abounding with blunders, like most translations from Eastern languages made during the middle ages, is an authentic one. Notwithstanding the great importance of the history of Ar-rází, it has never been printed; though manuscript copies are not uncommon. There is one in the library of the British Museum. The year of Ar-rází's death is not known; but as his history falls rather short of the reign of Abdu-r-rahmán, whose historiographer he was, we may safely conclude that he died before A.H. 350 (A.D. 961), the date of that sovereign's death.

RASKOLNIKI. [RUSSIAN CHURCH.]

RASO'RES. The *Rasores* of Illiger contained the following families and genera:—

Gallinacei.—*Numida*, *Meleagris*, *Penelope*, *Crax*, *Opisthocomus*, *Pavo*, *Phasianus*, *Gallus*, *Menura*, *Tetrao*, and *Perdix*.

Epollicati.—*Ortygis* (*Turnix*), *Syrrhaptes*.

Columbini.—*Columba*.

Crypturi.—*Crypturus* (*Tinamus*, Lath.).

Inepti.—*Didus*.

The order, which is the fourth in Illiger's method, is placed between the *Raptatores* and *Cursores*.

The order (v.) *Gallinæ* of Linnæus was placed between the *Grallæ* and the *Passeres*, *Struthio* being the last genus of the former, and *Columba* the first of the latter order.

The genera of *Gallinæ* are *Didus*, *Pavo*, *Meleagris*, *Crax*, *Phasianus*, *Numida*, and *Tetrao*.

The *Rasores* of Mr. Vigors consist of the families *Columbidæ*, *Phasianidæ*, *Tetraonidæ*, *Struthionidæ*, and *Cracidæ*

The *Rasores* of Mr. Swainson comprehend the families *Pavonidæ*, *Tetraonidæ*, *Struthionidæ*, *Columbidæ*, and *Megapodiidæ*.

The *Rasores* of Mr. G. R Gray embrace the families *Cracidæ*, *Phasianidæ*, *Tetraonidæ*, *Chionidæ*, and *Tinamidæ*.

RASPBERRY. The species from which the varieties of this fruit have been derived is the *Rubus Idæus*, a native of Britain and also of various other parts of Europe. The wide dispersion of the species is easily accounted for from the fact of its seeds resisting the powers of digestion in an eminent degree. Favourable localities would consequently become supplied with seeds by the migration of birds and other subjects of the animal kingdom. Seeds of a raspberry found in the body of a person who had been interred in Dorsetshire in the time of Hadrian, were sown and vegetated some years since. On its fruiting, it proved very similar to the red raspberry commonly met with in woods at the present day; and from this type, it may be observed, the most improved varieties are not by any means so far removed, with regard both to size and flavour, as are the generality of cultivated fruits from their original species.

For a selection, the following varieties may be enumerated:—Red Antwerp, Yellow Antwerp, Barnet, Bromley Hill, Cornish, Superb, Woodward's Red Globe, and Double Bearing.

The best soil for raspberries is a light rich loam. They will thrive well in sandy peat, provided it is not too dry. In all cases the ground for a plantation should be well trenched and manured previous to planting. The plants from suckers, of which there are generally abundance, should be planted in rows four or five feet apart, and three feet from plant to plant in the row. When planted they should be cut to within six inches of the ground; for although this is not absolutely essential, yet by so doing the shoots for the following season are greatly strengthened.

Pruning should be performed in autumn. It consists in first clearing off all dead portions, and retaining only a few of the strongest summer shoots of each plant, which should be shortened according to their strength, generally at a bend, which indicates where the shoot becomes weak, near the extremity. In the following summer the shoots just mentioned bear the fruit, whilst others spring up at their base for a succession; and in all cases succession shoots should be disposed so as neither to crowd the fruiting portion nor each other.

The ground of a raspberry plantation should be kept loose and supplied with well-rotted manure, but in so doing a fork should be used in preference to a spade, in order to preserve the roots as much as possible, and the roots should not be at all disturbed after active vegetation takes place in spring. Notwithstanding the best management in these respects, it becomes adviseable to make a new plantation in fresh soil after four or five years; for the roots diffuse themselves so thoroughly in every portion of the soil near the stools, that it soon becomes exhausted.

The fruit of the raspberry is extensively used in a variety of ways, both by the cook and the confectioner, and also in the preparation of cordial spirituous liquors.

RASTADT is a town with a population of 5680 inhabitants, in the grand-duchy of Baden, on the river Murg, not far from the Rhine. It is regularly built. Among the public buildings is the Favorita, a fine palace, built on the model of that of Versailles, and till 1771 the residence of the margrave of Baden. There are three churches, the principal of which is reckoned very handsome; two chapels; a lyceum; and a Roman Catholic seminary for the education of schoolmasters. The manufactories of starch, succory (as a substitute for coffee), snuff, and tobacco are flourishing. A manufactory of papier-mâché produces very handsome articles, which are highly esteemed. The other manufactures are fire-arms, mathematical and philosophical instruments, and carriages. Rastadt has been the scene of important negotiations. In 1713, Prince Eugene and Marshal Villars commenced the negotiations which terminated the war of the Spanish succession by the peace of Rastadt, on the 6th of March, 1714. The German empire not being included in this peace, a separate treaty was concluded by Eugene and Villars on the 7th of September, 1714, which terminated the war between France and the empire.

On the 9th of December, 1797, a congress was assembled at Rastadt, under the mediation of Prussia and Austria, to negotiate a peace between France and the German empire, which was dissolved by the emperor on the 7th of April, 1799. The French ambassadors, Roberjeot, Bonnier, and Jean Debry, after the interruption of the negotiation, left Rastadt, on the 28th of April, at nine in the evening, provided with passports from Baron Albini, envoy of the elector of Mayence; but they were attacked, about five hundred paces from the suburb, by a troop of hussars of the regiment Barbaczi. Roberjeot and Bonnier were killed. Jean Debry, though wounded, and the secretary Rosenstiel, escaped to Rastadt, and were escorted to the frontier by Szekler hussars. Notwithstanding the strict investigation ordered by the Diet at Ratisbon, and conducted by the archduke Charles, no satisfactory evidence was obtained respecting the authors of this crime.

RASTALL, or RASTELL, JOHN, one of our early printers, is said by Bale to have been a citizen of London, and by Pits a native of that city. Wood says he was educated in grammar and philosophy at Oxford, and returning to London, set up the trade of printing. The first work which bears his name as printer, with a date, was published in 1517, the last in 1533. There are numerous others without dates. His residence was at the sign of the Mermaid, at Paul's Gate next Cheapside. He married Elizabeth, sister to Sir Thomas More, with whom Herbert supposes he became intimate in consequence of being employed to print Sir Thomas's 'Dyalogue' on the worship of Images and

Reliques, published in 1529; but, as will hereafter be seen, his eldest son was born in 1508.

Bale and Pits ascribe the authorship of various works to John Rastall; the most remarkable of which is his 'Anglorum Regum Chronicon, or Pastyme of People,' a work of extreme rarity, reprinted in 1811 in the 'Collection of English Chronicles.' He translated from French into English the Abridgement of the Statutes before the reign of Henry VII., and also abridged those of that reign which were made in English, as likewise those of Henry VIII., including the twenty-third and twenty-fourth of his reign. He also compiled several law-books. Of these, his 'Exposition of Law Terms and the Nature of Writs,' and the book called 'Rastall's Entries,' continued long in use.

Wood says that Rastall, by frequent conferences with Sir Thomas More, improved his knowledge in various sorts of learning, which is probable; but he omits to notice, what is more important, that Rastall became a convert to the reformed religion by means of a controversy with John Frith. Rastall published 'Three Dialogues,' the last of which treats of purgatory, and was answered by Frith. On this, Rastall wrote his 'Apology against John Frith,' which the latter answered with such strength of argument as to make a convert of his opponent. Rastall also wrote a book called 'The Church of John Rastall,' which, being in the list of prohibited books published by Bishop Bonner, annexed to his injunctions in 1542, is supposed to have contained some retractation of his former opinions, at least of what he had written concerning purgatory.

He died at London, in 1536, leaving two sons, William and John; the latter afterwards a justice of the peace. The notice of the former immediately follows.

RASTALL, WILLIAM, was born in London, in 1508, and about 1525 was sent to Oxford, which he left without taking a degree, and entered at Lincoln's Inn for the study of law. In the first of Edward VI. he became autumn or summer reader of Lincoln's Inn; but on the change of religion, he retired with his wife to Louvain, whence he returned on the accession of Queen Mary. In 1554 he was made a serjeant-at-law, one of the commissioners for the prosecution of heretics, and, a little before Mary's death, one of the justices of the Common Pleas. Queen Elizabeth renewed his patent as justice, but he preferred retiring to Louvain, where he died, August 27, 1565. His wife, who died in 1553, on their first going to Louvain, at the age of twenty-six, was the daughter of Dr. John Clement, one of the physicians sent by Henry VIII. to Cardinal Wolsey during his last illness.

From 1530 to 1534 (Dibdin, in his edition of Herbert's 'Ames,' thinks till 1554), William Rastall carried on the business of a printer, in conjunction with his practice as a lawyer. When Justice Rastall, he published 'A Collection (abridged) of the Statutes in Force and Use,' in 1557, often reprinted.

(Wood's *Athen. Oxon.*, edit. Bliss, vol, i., col. 100; Dibdin's edit. of Herbert's *Typogr. Antiq.*, vol. iii., pp. 81-110, 370-383; Chalmers's *Biogr. Dict.*, vol. xxvi., p. 51-54.)

RAT. [MURIDÆ, vol. xv., p. 506.] Few animals are more destructive of every kind of grain than rats. When a barn is infested with them, it is scarcely possible to get rid of them. They will leave it for a time, and the farmer imagines that they are all destroyed; but no sooner is the corn brought in than they resume their depredations. There are means however of destroying them, and some of these means are equally effectual and ingenious. The most obvious way of destroying rats is to poison them, which appears an easy matter; but it is not so without an accurate knowledge of the habits of these creatures. Their sense of smelling is more acute than we can well conceive, and their caution is not easily deceived. It is difficult to entice them with food when they have plenty of grain to satisfy their hunger. Patience and perseverance alone can lull their caution to rest.

The principle on which all rat-catchers proceed is to entice the rats to some particular spot, convenient for their future operations. There are some strong scents which these animals seem to delight in; and, by means of these, their natural sagacity is deceived. Oil of rhodium, of carraway, or aniseed, and musk, are great favourites with rats. Rags, impregnated with these, and which have not been in contact with any part of the body of a man, being laid, as if by accident, will induce them to come out of their hiding-places in the night, and frequent the spot where the smell attracts them. Gradually they will become familiarised with the place; and pieces of tallow or cheese or malt-dust may be placed near without exciting their suspicion. After they have been fed for a time, they will readily eat anything that may be thrown down, provided it has not been touched by the hand without the covering of a glove properly scented. It will take some time to accomplish this; and when they are to be poisoned, a quantity of poisoned food, similar to what they have been accustomed to feed on, must be prepared, sufficient to poison all those which are supposed to frequent the place. The poisons commonly used are arsenic, nux vomica, powdered Spanish flies, and cocculus indicus, which intoxicates them, so that they may be taken by the hand. A small chamber, or a large chest or box, is convenient to collect the rats; and in order to induce them to go in, pieces of toasted cheese or red-herring are trailed along the ground from the rat-holes to the place where it is wished that they should assemble. As soon as they have been accustomed to find food which they like, they will all come to it in the night; and they can be poisoned, or caught by some contrivance by which the only entrance to the place or box can be suddenly closed. When traps are set, they should be left open for a time, and the rats allowed to go in and out without hindrance, till they crowd together in them, and can be taken in great numbers. When rats have been caught in a trap, and have soiled it with their excrements, it should not be washed, nor much handled: it should be left in the same spot, as long as any rats are caught. Any change of position excites their caution. An ingenious trap is made by stretching a piece of parchment over the open end of a cask, and enticing the rats to eat the food laid upon the parchment. When they have evidently been there to feed, cross cuts, a few inches long, are made in the parchment with a penknife; and in the bottom of the tub, which has four inches of water in it, a brick is set on its edge, so as just to rise out of the water. The rats coming for food, as usual, some one soon slips through the parchment, and, falling into the water, seeks refuge on the brick: as more fall in, they fight for the possession of the brick, and their noise attracts all the rats within hearing. Thus it is said that a great number may be caught in one night. In the 'Cyclopædia of Agriculture,' by Loudon, there is a description of a very complicated trap for rats, which appears very ingenious; but whether it is effective we have not had an opportunity of proving.

RATANY, RHATANY, or RATANHI'A, is the Krameria triandra of botanists; a half-shrubby plant found on the dry gravelly soil of Peru, whose root is excessively astringent, and is exported to Europe on that account. The stem lies prostrate, is two or three feet long, and covered with silky hairs. It has oblong, sharp-pointed, undivided, hoary leaves, and solitary, dull brown flowers, succeeded by a bur-like fruit. The extract of this root is a powerful styptic and tonic. The bark is turned black by iodine, and contains much tannin. It is used medicinally in this country as an astringent medicine in passive bloody or mucous discharges, weakness of the digestive organs, and even in putrid fevers. Its powder, mixed with charcoal, forms excellent tooth-powder.

RATA'RIA. [CIRRHIGRADA, vol. vii., p. 201.]

RATE, an assessment levied upon property. Rates are of various kinds, and are denominated with reference to the objects to which they are applied.

Church-rates are payable by the parishioners and occupiers of the land within a parish, for the purpose of repairing, maintaining, and restoring the body of the church and the belfry, the churchyard fence, the bells, seats, and ornaments, and of defraying the expenses attending the service of the church. The spire or tower is considered part of the church. The duty of repairing and rebuilding the chancel devolves on the rector, or vicar, or both together, in proportion to their benefice, where there are both in the same church. But by custom the parishioners may be liable to repair the chancel; and in London there is a general custom to that effect. Church-rate exists in England by virtue of the common law; nothing is known as to its commencement or introduction. In the early period of the church there appears to have been a division of the tithes,—either tripartite, one portion to the clergy, one to repairs of the church, and one to the poor; or quadripartite, one to the bishop, the other three to the clergy, the church, and the poor. That period was before the existence of parishes, when the only ecclesiastical division was the episcopal district or diocese, then called parochia. At that time the bishop resided at the cathedral church, together with his clergy, and on him devolved the duty of repairing the church, caring for the poor, and supplying ecclesiastical ministry. It was then the duty of every Christian man to pay to the bishop not only the decimæ, or tithes, but also the ecclesiæ census, church-scot, and the nummus eleemosynarius (alms money). The object to which church-scot was devoted is not known. It was also the duty of the bishop to admonish even the king that the temples of God be properly furnished; so that some other contribution seems to have been expected from the laity. There is no symptom that any alteration of usage occurred when the local endowment of churches was introduced. Church-rates, or something equivalent, certainly appear to have been in existence as a payment by the laity, independent of tithes, in the time of Canute, whose 63rd law, 'de fano reficiendo,' states that all persons ought of right to contribute to the repair of churches.

Church-rates are imposed by the parishioners themselves, at a meeting summoned by the churchwardens for that purpose. Upon the churchwardens, conjointly with the minister, devolves the care of the fabric of the church and the due administration of its offices. With a view to provide a fund for such expenses, it is the duty of the churchwardens to summon parish-meetings for the purpose of levying rates; and if they neglect to do so, they may be proceeded against both civilly and criminally in the ecclesiastical courts. A mandamus also is grantable to compel such meeting to be held. If the parish fail to meet, the churchwardens may themselves impose a rate. But if the meeting should assemble, it rests with the parishioners themselves to determine the amount of the rate; and they also, it would seem, have authority to negative the imposition of a rate altogether.* The only mode of compelling the parishioners to impose one is by ecclesiastical censures and laying the parish under interdict. The existing poor-rate of the parish is generally taken as the criterion for the imposition of the church-rate. All property in the parish is liable except the glebe-land of that parish and the possessions of the crown. Stock in trade is not generally rated, but a custom may exist rendering it rateable in a particular parish. The ecclesiastical courts have the exclusive authority of deciding on the validity of a rate, and the liability of a party to pay it; but a rate-payer cannot by an original proceeding in those courts raise objections to a rate for the purpose of quashing it altogether. If he wishes to dispute it, he ought to attend at the vestry, and there state his objections; if they are not removed, he may enter a caveat against the confirmation of the rate, or refuse to pay his assessment. In the latter case, if proceeded against in the ecclesiastical court, he may in his defence show either that the rate is generally invalid, or that he is unfairly assessed. The consequence of entering a caveat is an appeal to the ecclesiastical judge, who will see that right is done. There appears some reason to doubt whether the grounds on which a poor-rate is held to be bad because retrospective, are on principle applicable to a church-rate. The ecclesiastical courts have however decided that a retrospective church-rate is bad. Previously to 53 Geo. III., c. 127, the only mode of recovering church-rates from parties refusing to pay was by suit in the ecclesiastical court for subtraction of rate. By that statute, where the sum to be recovered is under 10*l.*, and there is no question as to the validity of the rate, or the liability of the party assessed, any justice of the county where the church is situated may, on complaint of the churchwarden, inquire into the merits of the case, and order the payment. Against his decision there is an appeal to the quarter-sessions. By several statutes, principally the 58 Geo. III, c. 45, and 59 Geo. III., c. 134, acts passed for the promotion of building churches, the common-law powers of churchwardens have been varied, and extended so as to enable them to raise money on the security of church rates, and to apply them for the enlargement, improvement, &c. of churches, and for the building of new ones, &c. &c. As to other rates, see SEWERS, SHIRE, WAY.

(Lyndwood; John de Athon; Selden's *History of Tithes*; Gibson's *Codex*; Burn's *Ecclesiastical Law*; Rogers's *Ecclesiastical Law*, 1840.)

* In Burder v. Veley, the question was raised whether the churchwardens had power to impose a rate after the parishioners in vestry assembled had negatived the imposition. The Court of Queen's Bench, after hearing elaborate arguments, and taking time to consider, determined that they had no such power. The case has since been argued in error, and the court have not yet pronounced their decision.

RATEL. [URSIDÆ.]

RATHKEALE. [LIMERICK.]

RATIO. One of the most frequent mathematical terms has no other name in our language than a Latin word which is but a bad translation from the Greek of Euclid. The older English writers introduced the word *reason*, as a translation of ratio, which completed the confusion; for it is easier to attach any meaning we please to a word in a dead language than to the literal translation of it in our own.

The word ratio is the translation of λόγος, as used in the third definition of the fifth book of Euclid, which is *Λόγος ἐστὶ δύο μεγεθῶν ὁμογενῶν ἡ κατὰ πηλικότητα πρὸς ἄλληλα ποιὰ σχέσις*. This has been translated as follows:—By Athelard (in what is called Campanus's translation from the Arabic), 'Proportio est duarum quantecunque sint ejusdem generis quantitatum certa alterius ad alterium habitudo.' By Billingsley, in the earliest English translation 'Reason is an habitude of two magnitudes of the same kind, compared the one to the other, according to quantity.' By various later English writers, 'Ratio is a mutual habitude of two magnitudes of the same kind with respect to quantity.' By Gregory, in his translation which accompanies the Greek, 'Ratio est duarum magnitudinum ejusdem generis secundum quantuplicitatem mutua quædam habitudo.'

The common translation partakes more of the confusion of the Arabic than of the clearness of the Greek; and it will be worth while to offer some remarks on the probable meaning of Euclid. In the first place, let it be observed that he never attempts this vague sort of definition except when, dealing with a well-known term of common life, he wishes to bring it into geometry with something like an expressed meaning, which may aid the conception of the thing, even though it does not furnish a perfect criterion. Thus, when in speaking of a straight line, he says that it is the line which lies evenly (*ἐξ ἴσου κεῖται*) between its extreme points, he merely calls the reader's attention to the well known term *εὐθεῖα γραμμή*, tries how far he can present the conception which accompanies it in other words, and trusts for the correct use of the term in the axioms which the universal conception of a straight line makes self evident. Let us suppose him doing the same thing here, and we shall find that the definition before us, considered with reference to the place it is in, and the subsequent purpose which it serves, is as clear as the translation of it is confused.

The term λόγος contains (λεγ, λογ), a root the original meaning of which seems to have contained the idea of collection or bringing together. It is certain however that the secondary sense which it obtained in common usage was that of speaking; so that the first sense in which λόγος appears in writings is that of speech. Subsequently, speech being the distinctive character of reasoning beings, and their mode of communication, the word was applied to every sort of communication, not only with reference to the mode of communication, but also to its subject; thus explanation, defence, apology, teaching, assignment of cause or reason, &c., are among the recognised uses of the word. The Latin translators have taken the geometrical word as being properly translated by *ratio*, a word which may very well signify the technical meaning of λόγος, but has no reference to its primary meaning. For ratio, in its primitive sense, means rather computation or reckoning than reason.

But what has speech to do with the sense of ratio in geometry? Robert Recorde answers this question (NUMERATION, vol. xvi., p. 367) when he reduces his pupil to silence by forbidding him the use of number, and asking him questions. Numbers are but certain ratios, and ratio is a generalised idea of number. Our gift of speech with reference to magnitudes would be altogether annihilated if we did not consider a certain habitude or mode of existence which they have, or more correctly a certain conception of our own, which always accompanies the presence of two magnitudes, which prompts us to inquire how many times one is contained in the other. A foot being known, speech can carry a correct knowledge of other lengths all over the world; but let it be attempted to describe a foot in words without reference *κατὰ πηλικότητα* to some other magnitude, and all the powers of language utterly fail. We conceive then that in this definition Euclid simply conveys the fact that the mode of expressing quantity in terms of quantity is entirely based upon the notion of *quantuplicity* or that relation of which we take cognizance when we find how many times one is contained in the other.

The word πηλικότης has been translated 'quantity,' by many editors, which makes nonsense of the whole; for magnitude has hardly a different meaning from quantity, and a relation of magnitudes with respect to quantity may give clear ideas to those who want a word to convey a notion of architecture with respect to building, or of battles with respect to fighting; and to no others. Wallis, we believe, restored the true meaning of the word, and was followed by Gregory, as seen above: and Euclid himself, in another place, shows in what sense he used it. In the fifth definition of the sixth book (omitted by many editors), he says that a ratio is compounded of two other ratios when the πηλικότητες of the latter *multiplied* (πολλαπλασιασθεῖσαι) together, make the former. Now, this would be unmeaning if the Greek word meant simply quantities, unless they were quantities represented by numbers (though Gregory has here forgotten his own previous correction, and writes quantitas instead of quantuplicitas). The lexicographers generally give 'quantitas;' but they are not for the most part adepts in the mathematical use of terms implying relations of magnitude.

The first and rough notion of ratio being thus given, we may find a synonyme for the word in the more intelligible term *relative magnitude.* Six feet, though greater than three feet, is, relatively to four feet, a less magnitude than three feet is, relatively to one foot: the number of times which six feet contains four feet is less than the number of times which three feet contains one foot. The relative magnitude of six to four is less than the relative magnitude of three to one; or the ratio of six to four is less than the ratio of three to one.

Given two magnitudes, how are we to find the means of expressing the first in terms of the second? Euclid answers this question, when it can be answered, in the tenth book, by giving the rule for finding the greatest common measure of two magnitudes, in which he employs a process exactly the same as that of the arithmetical rule in common use. Let A and B be two magnitudes (say lines), of which B is the less. From A cut off a part equal to B, do the same again, and so on, until R_1, the part left, is less than B. Say it is found that A contains 5 times B and R_1. Measure R_1 upon B in the same way, and suppose B contains 4 times R_1 and R_2. Suppose now that R_1 contains 6 R_2 and R_3, and also that R_2 contains exactly 7 times R_3. We have then

$$R_2=7R_3,\ \ R_1=6R_2+R_3=43R_3$$
$$B=4R_1+R_2=172R_3+7R_3=179R_3$$
$$A=5B+R_1=895R_3+43R_3=938R_3.$$

We have then the same means of expressing A in terms of B that we have of expressing 938 in terms of 179: or we should give the power of deducing either when the other is known, by saying that the 179th part of the first is the same magnitude as the 938th part of the second.

But it may happen that the magnitudes have no common measure [INCOMMENSURABLE], in which case the preceding process would never have an end, and the means of expression would fail. We can describe the diagonal of a square as a part of a certain figure, and the description is perfect; but if we attempted a description *secundum quantuplicitatem,* we should never succeed; for no possible line exists of which it can be said that the diagonal of a square and its side both contain that line exactly. Such quantities are called by Euclid ἄλογοι, irrational, or having no ratio; and in the primitive meaning of the term this is correct, for there is no quantuplicitative mode of expressing one by the other. But the term ratio, both in Euclid and all other writers, immediately acquires another sense; and it is this new sense in which we proceed to speak of ratio. Since the relative magnitude of two quantities is always shown by the quantuplicitative mode of expression, when that is possible, and since proportional quantities (pairs which have the same relative magnitude) are pairs which have the same mode (if possible) of expression by means of each other; in all such cases sameness of relative magnitude leads to sameness of mode of expression; or proportion is sameness of ratios (in the primitive sense). But sameness of relative magnitude may exist where quantuplicitative expression is impossible; thus the diagonal of a larger square is the same compared with its side as the diagonal of a smaller square compared with *its* side. It is an easy transition to speak of sameness of ratio even in this case; that is, to use the term ratio in the sense of relative magnitude, that word having originally only a reference to the mode of expressing relative magnitude, in cases which allow of a particular mode of expression. The word irrational does not make any corresponding change, but continues to have its primitive meaning, namely, incapable of quantuplicitative expression. And it is worth noting that this of itself shows that the original meaning of λόγος referred to expression, not to the thing expressed; for ἄλογος (not having a ratio) would have been absurd as applied to incommensurable quantities, if the primitive mathematical meaning of the first word had coincided with its modern one.

The idea of relative magnitude is one which strikes us in all cases in which we compare the parts of an original with the corresponding parts of any model or imitation. It does not closely connect itself with any mode of expression or measurement: if a part of the model were only in a slight degree too large or too small, the detection of the error might require a formal measurement, but anything which is very much out would be rejected by one glance of the eye. Let us suppose now that the formal measurement is attempted. The first and simplest notions of relative magnitude are gained from repetition; and the ideas of two, three, four, &c., originally used in their simple cumulative sense, soon become the representatives of those simple relative magnitudes which are suggested by pairs in which one is quantuple of the other. The next step is to those magnitudes in which neither is quantuple of the other, but both are quantuple of a third: from which we learn how, admitting aliquot parts, to extend the mode of expression. Thus, of the magnitudes 10 R and 7 R, we see that every relation of quantuplicity can be derived from the simple numbers 10 and 7: the first number is $1\frac{3}{7}$ of the second, a mode of expression which equally applies to the magnitudes 10 R and 7 R. The preceding would be unnecessarily laborious if it were not as an introduction to the remaining and most frequently occurring case of quantities, the relative magnitude of which cannot be expressed by that of number to number; or incommensurable magnitudes.

Let D and S be two incommensurable magnitudes: how are we to describe their relative magnitudes? That they have a definite relation is certain; suppose, for precision, that S is the side of a square, and D its diagonal; any alteration of D, or any error in D, S being given, would make the figure cease to be a square. There are many mathematical notions in which accuracy is not attainable in finite terms, but is the limit towards which we approach when number or magnitude, as the case may be, is increased or diminished without limit. In the present case the expression of ratio or relative magnitude, which is not accurately attainable by one or more relations, can be continually amended by adding one or more relations, until the inaccuracy of the mode of expression is rendered as small as we please: in such a case, accuracy must be imagined to reside in the supposition of an infinite number of given, or at least of attainable, relations.

To explain our meaning, suppose that the person whom we address is altogether ignorant of the relative magnitude of the diagonal D and the side S. He asks for a relation, and knowing the mode of dealing with the ratios of commensurables, naturally desires to know how many diagonals make an exact number of sides. If we could answer this question, if for instance we could say that 100 diagonals make 142 sides exactly, the question would be settled: for an arithmetical rule would always deduce the diagonal when the side is given. But we are obliged to reply, that no number of diagonals whatsoever will make an exact number of sides. He then asks how he is to form a perfect conception of the diagonal; we answer by placing two equal sides at right angles to one another, and joining the extremities. This, he replies, and properly, is not a mode of finding the relative magnitude, which is something connected with magnitudes only, and that the permission given by Euclid to join two given or determined points is not any real determination of the included length. We then tell him that it is at his pleasure to name a fraction of the side, and we can express the diagonal with an error not so great as that fraction; he names, say one-millionth of the side, and we give him the promised information in telling him that 1,000,000 of diagonals exceed 1,414,213 sides, but fall short of 1,414,214 sides. The consequence is, that the diagonal lies between 1·414213 and 1·414214 of the side: these differ from one another by one-millionth of the side, and the error of the diagonal is of course less. If he should ask how he is to carry this process yet further for himself, we give him the arithmetical symbol $\sqrt{2}$, and instruct him how to perform the arithmetical operation of approximating to its value. In this we show him how to find between what number of sides any number of diagonals lies: and in so doing we give the ratio of the diagonal to the side, as far as the nature of the case will admit of its expression.

The relative magnitude, then, of two magnitudes is given, when the place of any multiple whatsoever of the one among the multiples of the other can be found from the data. For example, we carry on the *multiple scale* of the side and diagonal of a square, in the power of extending which ad infinitum lies that of expressing the ratio, so far as expression is possible, and of absolutely comparing the ratio with others, in as accurate a manner as if expression had been perfect.

S, D, 2S, 2D, 3S, 4S, 3D, 5S, 4D, 6S 7S, 5D, 8S, 6D, 9S, 7D, 10S, 11S, 8D, 12S, 9D, 13S, 14S, 10D, 15S, 11D, 16S, 12D, 17S, 18S, 13D, 19S, 14D, 20S, 21S, 15D, &c.

In this table we see, for instance, that 10 diagonals are more than 14 and less than 15 sides, and so on. The only doubt that can possibly remain may be thus expressed:—Is the preceding scale a property of the diagonal and of nothing else? May there not be a length so near to the diagonal that its multiples shall never fall out of the same intervals as those of the diagonal? Let K be a given quantity, no matter how small; we say that it is impossible that all the multiples of D+K can lie in the same places among the multiples of S as the multiples of D. Take m times both: then m(D+K) and mD differ by mK. Now however small K may be, it is possible to take m so great that mK shall exceed S, or any multiple of S previously named: whence the thing asserted is evident. The definition of the ratio of S to D lies, then, in this scale; or rather, whatever the definition may be, the mode of finding all relations between S and D lies in the formation of this scale, so far as may be necessary for the purpose in hand. The definition of proportion is then contained in sameness of multiple scales; that is, D is to S as A to B, when any multiple whatever of D is contained between the same two multiples of S, that the same multiple of A is contained between of B. We here come to the subject of PROPORTION, which the reader should now consult as a continuation of the present one.

The next step to be made is rather an abstract one: ratio itself is a magnitude, that is, the relative magnitude of one magnitude to another is itself a magnitude. To understand this, remember that by magnitude we do not mean merely physical magnitude, as size, weight, length, &c., but any conception of our minds as to which it is evident that either greater, equal, or less, must be a term applicable to every two such conceptions, and that a mode of measuring excess or defect, as also of ascertaining equality, can be found. This is easily done as follows, with which the considerations connected with greater and less ratio in the article PROPORTION may be read:—Which is the greater ratio, that of P to Q, or of A to B? that is, which magnitude is relatively greater, P as compared with Q, or A as compared with B? Choose any quantity, Z, and let the ratio of A to B be that of X to Z, while that of P to Q is that of Y to Z. The question is then reduced to the following: which is greatest, X considered relatively to Z, or Y relatively to the same Z? The answer obviously depends upon which is absolutely the greater of the two, X or Y. Let X be the greater, then the ratio of A to B is greater than that of P to Q. But in what relation is the ratio of A to B greater than that of P to Q? Repeat the transformation, and the ratio of X to Z is greater than the ratio of Y to Z, in exactly the same manner as X is greater than Y: that is, the ratio of X to Y is the ratio of the ratio of A to B to that of P to Q. To find the ratio of two ratios then, namely, A to B, and P to Q, let

$$A : B :: X : Z$$
$$Q : P :: Z : Y$$

and the ratio of X to Y is the ratio of ratios required. This process is called by Euclid the composition of the ratios of A to B and of Q to P; that is, he would say that the ratio of the ratios of A to B and of P to Q is the ratio compounded of the ratios of A to B and of Q to P. Later writers called this process of composition by the name of addition*; though it may easily be made to appear that where one of the ratios is that of number to number, composition is multiplication of the corresponding terms. Thus, to compound the ratio of the diagonal D and the side S with that of 7 to 3, we have

$$D : S :: 3D : 3S$$
$$7 : 3 :: 7D : 3D$$

whence the ratio of 7D to 3S is the compounded ratio. This term of addition was an anticipation, to a small extent, of the principle of logarithms. Thus, if

$$A : B :: V : W$$
$$A : B :: W : X$$
$$A : B :: X : Y$$

the ratio of V : Y, compounded of the ratios of A to B, A to B, and A to B, was said to contain the ratio of A to B three times. Thus if any given ratio (as A to B) were taken as a measure, all other ratios might be measured by it, either exactly or approximately. Thus, if the ratio of V to Z were required to be measured by the ratio of A to B, there would be taken $V : V_1$, $V_1 : V_2$, $V_2 : V_3$, &c., all the same ratios as A : B; if V_n be the last of these which is less than Z, and V_{n+1} the first which is greater, it would be said that the ratio of V to Z contains that of A to B more than n times and less than $n+1$ times. Hence arise the use of the duplicate (or double) ratio, as being the ratio compounded of that of A to B with itself; of triplicate (a triple ratio) as that compounded of the ratio of A to B, A to B, and A to B, and so on. The following summary shows both the old and modern algebraical use of these terms, the capital letters representing magnitudes, the small letters numbers.

Duplicate ratio of A to B. The ratio compounded of those of A to B, and A to B. Do. of a to b is that of a^2 to b^2.

Triplicate ratio of A to B. The ratio compounded of the duplicate ratio of A to B, and of A to B. Do. of a to b is that of a^3 to b^3. And so on.

Subduplicate ratio of A to B. The ratio whose duplicate ratio is that of A to B. Do. of a to b is that of $\sqrt{a}$ to $\sqrt{b}$.

Subtriplicate ratio of A to B. The ratio whose triplicate ratio is that of A to B. Do. of a to b is that of $\sqrt[3]{a} : \sqrt[3]{b}$. And so on.

Sesquiplicate ratio of A to B. The ratio compounded of that of A to B and its subduplicate. Do. of a to b is that of $\sqrt{a^3}$ to $\sqrt{b^3}$.

We have not spent any space in drawing the analogies, which are very close, between the doctrine of fractions and that of ratios. The reader who understands what we have here said, will easily supply this part for himself, remembering that when A and B are numerical, the fraction A÷B is the expression of the ratio of A to B. Modern writers employ fractions instead of ratios, and with great advantage. But the student who leaves untouched that consideration of ratio which includes incommensurables as well as commensurables will never be more than a mathematician to a certain number of decimal places.

The older writers on geometry, and even algebra, are frequently unintelligible to a reader who is not versed in the language of ratios as used by the Greeks and augmented by the inquirers of the middle ages. Many a young reader has met for the first time with what purported to be an explanation of logarithms in Halley's celebrated paper, which was prefixed to Sherwin's 'Logarithms,' and, we believe, to others. The following is a sample:—

'But first it may be requisite to premise a definition of logarithms, in order to render the ensuing discourse more clear, the rather because the old one, *numerorum proportionalium æqui differentes comites*, seems too scanty to define them fully. They may more properly be said to be *numeri rationum exponentes*, wherein we consider *ratio* as a *quantitas sui generis*, beginning from the *ratio* of *equality*, or 1 to 1=0; being affirmative when the *ratio* is increasing, as of unity to a greater number, but negative when decreasing; and these *rationes* we suppose to be measured by the number of *ratiunculæ* contained in each. Now these *ratiunculæ* are so to be understood as in a continued scale of proportionals infinite in number between the two terms of the *ratio*, which infinite number of mean proportionals is to that infinite number of the like and equal *ratiunculæ* between any other two terms, as the logarithm of the one ratio is to the logarithm of the other. Thus if there be supposed between 1 and 10 an infinite scale of mean proportionals whose number is 100,000, &c. *in infinitum*, between 1 and 2 there shall be 30,102, &c. of such proportionals, and between 1 and 3 there will be 47,712, &c. of them; which numbers therefore are the logarithms of the

* Euclid's words for compounding (συγκεῖσθαι and συντίθεσθαι) both imply addition.

rationes of 1 to 10, 1 to 2, and 1 to 3; and not so properly to be called the logarithms of 10, 2, and 3.'

The way in which the preceding would be put in our day is given in LOGARITHMS, p. 85. We leave it to the reader to satisfy himself that what is there said is a translation of the preceding into modern language.

For any one who would wish to see the manner in which the notion of ratio was formerly treated, we should recommend Meibomius 'De Proportionibus Dialogus,' Copenhagen, 1655, for the sake of the answer by Wallis, which is in the collection of his works (vol. i, p. 229), and was previously published in his 'Operum Mathem. pars prima,' Oxford, 1657.

RATIONAL. A quantity, algebraic or arithmetical, is rational when it can be expressed without the use of the signs of evolution, such as those of the square root, cube root, &c. [IRRATIONAL.]

RATIONALISM is a system of theology, which, as a system, began to be developed in Germany during the latter half of the last century. To understand the origin and character of this school of theology it will be necessary to take a glance at the state of theology previous to the appearance of Rationalism.

During the first half of the last century theology in Germany was what it had been during the seventeenth century; its literature was little more than a series of controversial writings, in which the disputed points were often discussed in a coarse and uninstructive manner, and most of the topics themselves were altogether unimportant. At the same time men of acknowledged talents in England and France abandoned Christianity altogether, and endeavoured by their writings to undermine its foundations. We allude to the numerous English deists, and to the school of Voltaire and his followers. These writers not only denied the historical authenticity of the biblical records, but declared them to be fabrications. Reimarus of Hamburg was the first German who adopted these and similar views, and he introduced them among his countrymen in a work called 'Die vornehmsten Wahrheiten der natürlichen Religion,' Hamb., 1754. Another still more important work by Reimarus consisted of several essays on various points in the New Testament. These essays were not printed, but distributed, in MS., among his most intimate friends. When Lessing was librarian at Wolfenbüttel, he obtained a copy of these essays, and, in 1773, began publishing them, under the title of 'Fragmente eines Ungenannten,' pretending that he had found them in MS. in the Wolfenbüttel library, whence they are generally called 'Die Wolfenbüttelschen Fragmente.' In these fragments, or essays, an attempt was made not only to show the improbability and impossibility of a revealed religion in general, but more especially to prove that the books of the Old and New Testaments were not of divine origin, and that the plan which Jesus endeavoured to realise was of a political nature. This scheme, it was further alleged, was thwarted by his execution, and his disciples, discouraged by this blow, are represented as having propagated a report of the resurrection of their master, and as having disguised their real object by cunningly introducing some modifications into their system. The publication of these fragments created an extraordinary sensation in Germany, and roused the theologians from their inactivity. The majority however remained faithful to their belief in the scriptures; but another class of German divines, though opposed to the views of the fragmentist and the deists, struck out a middle path. These were the Rationalists, who indeed went half way with their adversaries, in as far as they denied the divine origin of the scriptures, but they dissented from the deists, who affirmed that the Bible was the product of fraud, and they maintained that, notwithstanding all the apparent incongruities of the Bible, it was based on genuine historical foundations, to ascertain which was the problem of reason. The authors of the biblical books, according to the Rationalists, were not impostors, but men of moral purity, who, being deluded by the excited state of their imagination, considered things to be miraculous which were only natural occurrences. Other portions of the Bible, they said, which have hitherto been considered as recording supernatural events, need only to be divested of the figurative and allegorical mode of expression so peculiar to all Eastern nations, in order to appear as the records of ordinary occurrences. This mode of interpretation was the more readily adopted by a great number of theologians, as it had been and was then still applied to the fabulous stories of heathen antiquity. Attempts had been made to elicit real history from mythical traditions, by stripping them of their poetical embellishments and marvellous ingredients. But the skeleton which remained after such a process was generally imperfect and disjointed, and it could only be completed by supplying secondary and additional circumstances, which were thought necessary to make up something like a connected history, and which the writer himself was supposed to have overlooked or neglected, though the narrative did not contain any thing to justify such a supposition, and in many cases was even directly opposed to it. The history thus constructed out of the interpreter's imagination was offered as discovered truth, and this mode of interpretation, though in reality the most irrational, was called the rational method of interpreting the scriptures. To account for the way in which the supposed collateral circumstances and the minute details in the accounts of so many miracles arose, merely out of the psychological state of the beholder or reporter, would in most instances suggest to the mind of the reader of these rationalistic interpretations a greater miracle than that which they endeavour to explain away. This method moreover leaves such a wide field of speculation, that twenty expounders, each taking his own view of a case, and translating the supposed allegorical expressions into his own language, might possibly produce twenty different stories, all of which might with equal plausibility be elicited from the original report, and each might claim to be the true historical foundation. In fact, according to this theory, there is no end of probabilities and possibilities.

The theologians who first came forward as advocates of this new system were Semler, J. D. Michaelis, and J. G. Eichhorn. They directed their attacks against the deists as well as against the orthodox divines, but they confined the application of the rationalistic principle chiefly to the books of the Old Testament. Semler's principal works in this department are, 'Apparatus ad liberalem Veteris Testamenti Interpretationem,' Halle, 1773; 'Abhandlung von der Untersuchung des Kanons,' 4 vols., Halle, 1771-75, compare Semler's 'Leben, von ihm selbst verfasst,' 2 vols., Halle, 1781-82. The principal works of Michaelis are 'Einleitung in die göttlichen Schriften des alten Bundes,' 2 vols., Göttingen, 1750; 'Mosaisches Recht,' 6 vols., Frankfurt, 1770-75. Eichhorn was by far the most important writer of the school; he laid down and carried out the new principles in his 'Allgemeine Bibliothek der biblischen Literatur,' 10 vols., Leipzig, 1788-1801; 'Einleitung in das Alte Testament,' of which there appeared, in 1824, at Göttingen, the fourth edition, in 5 vols.; 'Einleitung in das Neue Testament,' in 2 vols., and several other works.

Eichhorn, whom we may consider as the representative of the new school, previous to the time when Dr. Paulus began to occupy a prominent position in it, sets out from the principle that the early history of the Jews should be considered in the same light and treated in the same manner as the early history of every other nation; and that a direct interference of the deity in the early affairs of all nations must either be admitted or denied. The reasons which led him to consider the fact of such a direct interference inadmissible in the case of other nations, led him to deny it in the case of the Jews also. Rejecting the views of the deists as unphilosophical and incompatible with the character of early history in general, he proceeds to state that it is natural to all nations in their primitive ages to speak of a divine interference in their affairs, wherever their ignorance concealed from them the real causes of the things which fall within their experience.

It is this belief, according to Eichhorn, which gives a form to all their ideas and expressions. But we, who live in a far more advanced and enlightened age, have neither reason to suppose that any miracles actually took place, nor that any kind of imposition was practised: we have only to translate the expression of those early ages into the language of our own time. In the infancy of mankind everything of which no direct cause appeared was referred to the intervention of supernatural powers; and accordingly all elevated thoughts, great determinations, useful inventions and institutions, and particularly dreams, were considered as the effects of a direct interposition of the deity; extraordinary knowledge and skill were looked upon by the people as proofs of supernatural power and of an intercourse with beings of a higher order. Moreover, not only the people, but the wise and great, were themselves fully convinced that they were acting under the immediate influence and were merely the especial favours of the Deity. Taking these premises for granted, and at the same time admitting that the biblical books were written by contemporaries, Eichhorn thought that all the facts of the Mosaic history might be explained as natural occurrences, without supposing, with the deists, that the writer was an impostor. The temptation and the eating of the forbidden fruit, the histories of Noah, Abraham, and Moses, are thus stripped of their supposed allegorical dress and of those features which it is supposed that they have received from the imagination of the writer, and are explained as natural events. According to Eichhorn, Moses was nothing but a great and benevolent patriot, who, after having long entertained the idea of delivering his countrymen from foreign slavery, was suddenly reminded of his scheme in a dream, and believing the dream to be from the deity, he represented it as a summons from Jehovah. The burning and smoking of Mount Sinai, according to this system of exposition, were only the effect of a fire which Moses kindled on the Mount for the purpose of keeping up the excitement of his people; and a storm with lightning, which fortunately happened at the same time, was a useful aid to him. The shining of his face was nothing but the consequence of great heat and excitement, which the law-giver as well as his people, not knowing the real cause of it, believed to be the effect of a direct interference of the deity.

This system of interpretation was, as we have observed, principally applied to the Old Testament, but the New Testament also contains passages which were too tempting to be passed over by the Rationalists. It was at first chiefly the appearance of angels in the New Testament on which Eichhorn tried the rationalistic interpretation, and all passages of this kind ought, according to this critic, to be considered as figurative expressions or allegories: thus a happy chance is represented as a saving angel; an internal joy, as the salutation of an angel; and great calmness and peace of mind, as a comforting angel, &c.

The way being thus prepared, the number of rationalistic divines increased, and their influence became apparent in many other departments of knowledge. A Utilitarian school had at the same time acquired considerable power; and as far as it endeavoured to instruct the people in the so-called useful sciences, and to do away with everything which was deemed superstitious, it went hand in hand with and supported Rationalism, which now began to be carried out in its whole extent with regard to the New as well as the Old Testament.

Among the works which gained the greatest popularity, we may mention K. F. Bahrdt, 'Briefe über die Bibel im Volkston,' 1782; Eck, 'Versuch über die Wundergeschichten des Neuen Testaments,' 1795; 'Die Wunder des Neuen Testaments in ihrer wahren Gestalt für echte Christusverehrer,' 1799; 'Natürliche Geschichte des grossen Propheten von Nazareth,' 1800. The two last works, which were published anonymously, were written by Venturini. Most of these, and the numerous other works of the same tendency, were written in a popular style; and those of Bahrdt had often a coarse and vulgar tone. But none of these writers equalled Dr. Paulus of Heidelberg, either in learning or ingenuity; and it is he who has most completely developed the whole system of Rationalism. His principal works are—'Philologisch-kritischer und historischer Commentar über das Neue Testament,' 4 vols., Lübeck, 1800–1804 (this work was republished in 1830–33, in 3 vols., with numerous alterations and corrections, under the altered title of 'Exegetisches Handbuch über die drei ersten Evangelien'); 'Das Leben Jesu, als Grundlage zu einer reinen Geschichte des Urchristenthums,' 2 vols., Heidelberg, 1828. Paulus first insists upon the necessity of distinguishing between those passages of the Bible in which the writers simply state facts and those in which they give their own opinions of them. A *fact*, according to him, is that which the writers describe as having taken place within their own experience; an *opinion*, on the other hand, is the manner in which they interpret an occurrence and trace it to what they conceive to be its causes. But as these two elements are in most cases interwoven and mixed up with each other in the biblical writings, Paulus considers it to be the chief object of the biblical critic to separate them, and to discover the genuine historic truth in the various disguises with which the opinions of the age and of the writer have surrounded it, and he thinks, with Eichhorn, that this object may be accomplished if the critic transports himself as much as possible to the scene of the events, and supplies such accessory and explanatory circumstances as may have been neglected or overlooked by the reporter or eye-witness. Thus the New as well as the Old Testament is deprived of its divine character, and all supernatural interference in the affairs of the Hebrews and in the introduction and establishment of Christianity is denied. Christ is no longer the son of God, but a wise and virtuous man; his miracles are either acts of friendship and humanity, and manifestations of his skill in the healing art, or the effects of a happy chance. In short, the whole history of the Bible assumes an aspect totally different from that of the original records, and from that which their authors manifestly intended; in fact it becomes a romance without any foundation except the assertion of the Rationalist that things did actually happen thus and thus.

A reaction against the spirit of this school manifested itself during the first ten years of the present century. The dreadful ravages caused by the French Revolution created a general desire to restore or maintain the good old times by returning to the religious and political institutions of past times. But although this reaction was successful in other departments, it had very little effect in theology, as it manifested itself rather in passive and retired mysticism than in energetic efforts against the system of the Rationalists. A vigorous opposition however began in 1810, which was called forth by the publication of Reinhard's 'Geständnisse,' in which Rationalism and Supernaturalism were declared to be diametrically opposed and utterly irreconcilable with each other. This assertion was denied by other theologians, who endeavoured to reconcile the two schools. The contest which then commenced, was carried on in a calm and philosophic spirit till 1817, when the centenary anniversary of the Reformation was celebrated in Germany, and the supernaturalistic party, headed by Dr. Harms of Kiel, endeavoured to make the question a practical one, and to draw to it the attention of the governments and of the whole German nation. The Rationalists were now universally decried as infidels, and as men who had forfeited all right to be called Christians; and innumerable works were written by the theologians of both parties to defend their opinions. The principal champions on the supernaturalistic side, besides Harms, were Hengstenberg and Tholuck; on the side of the Rationalists, Gesenius, Wegscheider, and Paulus. In these controversies the rationalistic theory itself almost disappeared, and the question assumed the more general character, whether the Protestant church should allow freedom of thought or not. This turn of the question induced many of the moderate Supernaturalists, who would not sacrifice their liberty of conscience, to side with the Rationalists. Their wish however was merely to bring about some kind of a reconciliation, and not to allow the question to become a national one. Their opinion was that it should be kept strictly within scientific limits, and confined to the learned. Although willing to make concessions to the Rationalists on many points, they were yet anxious to prevent any practical innovations.

After this fierce contest, which led to no decisive results, there followed a period of exhaustion and languor. The moderate party, consisting of men of both schools, increased, and repeated though fruitless attempts at reconciliation were made by them at different times. At last a complete indifference prevailed, and all hopes of producing any definite result seemed to be given up. Each party however continued to maintain its tenets. Some individuals from time to time endeavoured to renew the contest, but no lively or general interest was created on either side. One of the more important rationalistic works which appeared during this period was: 'Was heisst glauben, und wer sind die Ungläubigen?' by David Schulz, 1830.

Notwithstanding the wide breach between the two parties, approximations were made on both sides, so that the Supernaturalists as well as the Rationalists might each be divided into two parties. Some of the latter, such as Paulus, Wegscheider, Gesenius, Schulthess, Schulz, and others continued to consider reason as their only guide in matters of religion, and rejected every supernatural revelation; others, the so-called Supernaturalistic Rationalists, admitted indeed a supernatural revelation, but considered reason as the only means of recognising and acknowledging it; they thus still allowed reason to be the supreme judge in matters of religion. To this class of Rationalists belong Bretschneider, Von Ammon, Böhme, Hase, Klaiber, and others. A similar division exists among the Supernaturalists.

The view which the Rationalists had taken of the Scriptures contained some elements which have of late led to a new crisis in German theology. Some parts of the Scriptures, from which the Rationalists, with all their ingenuity, saw no hope of eliciting a genuine history, they had ventured to declare to be a mere legend, tradition, or mythus. This view was gradually applied to a great portion of the Old Testament, as in Bauer's *Hebräische Mythologie*, Leipzig, 1802. The various and profound investigations into antient profane history had led to similar results in other departments, and the hollowness of the Rationalist interpretation was either loudly proclaimed or tacitly acknowledged by all parties. The consequence was either a return to the supernaturalistic view, or further progress in the path which had been opened by the Rationalists themselves. Those Rationalists who could not do the former now applied the principle, to which they had formerly recourse only in cases of extreme difficulty, to the whole body of the early and miraculous portions of the Scriptures, which they placed on the same footing with the early and fabulous stories of antient Greece and Rome, and considered as a mythical history not written by eye-witnesses or contemporaries, and only recorded after it had been handed down by tradition through many generations. According to this view, all the events in the Bible are either natural events, such as occur in the history of other nations, and which must be examined according to the general principles of historical criticism, or they are of a miraculous and supernatural character, and must for this reason be rejected as not historical, like the fabulous accounts of antient mythology. As the rationalistic school directed its first attacks against the deists, so the mythical school, though diametrically opposed to the Supernaturalists, has hitherto directed its main efforts against Rationalism. We must nevertheless consider this last school as essentially rationalistic, or as a second form of Rationalism, in as far as, like Rationalism in its first form, it takes reason for its sole guide, and denies all supernatural revelation. The only difference is that it denies the Biblical records to be the works of eye-witnesses and contemporaries, and hence draws the conclusion that it is utterly impossible to elicit from those portions which are supposed to consist of mythical stories anything like a true and connected history.

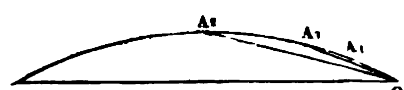
Up to the year 1835, this second form of Rationalism had been applied only partially, and chiefly to portions of the Old Testament; but it has lately been carried out in its full extent with reference to the books of the New Testament, by Dr. David Frederick Strauss, in his *Das Leben Jesu kritisch bearbeitet*, in 2 vols. The first edition appeared in 1835-36; a second was published in 1837, and a third in 1838, which is now out of print. This work, the production of a man of great learning, profound reflection, and critical skill, has called forth a host of polemical works, but the best efforts against it have been made by the supernaturalistic school. Rationalism in its first form seems to have received its death blow from this work and the various controversial writings of Strauss and others, while the new school is making rapid progress. The contest between it and the Supernaturalists is still going on, and is, with few exceptions, conducted in a calm and purely philosophic manner. Both parties have been honest enough to give way whenever any of their disputed points have been proved to be untenable. This is manifest from the 'Life of Christ' lately published by Neander, and from the different editions of the work of Strauss.

For a further account of the history of Rationalism the English reader may consult *The State of Protestantism in Germany*, by the Rev. Hugh James Rose, London, 1829; *An Historical Enquiry into the probable Causes of the Rationalist Character lately predominant in the Theology of Germany*, by Rev. E. P. Pusey, London, Part I., 1828; Part II., 1830; *Reply to the Rev. H. J. Rose's Work on the State of Protestantism in Germany*, by Dr. K. G. Bretschneider, tranlated by a Layman of the Church of England, London, 1828.

RATIOS, PRIME AND ULTIMATE. These terms were first introduced, at least in a system, by Newton, who preferred them to the terms suggested by his own method of fluxions. The first section of the Principia contains the development of their meaning, with various propositions enunciated in their language. In the articles LIMIT and INFINITE we have already had the same notions to consider, couched in different words; but when we remember that the only sure foundation of the differential calculus, that is, of all the higher part of mathematics, must rest upon these notions, it will be worth while to dwell a little upon Newton's form of expression, and his method of employing it. The notions in question actually form part of the knowledge of many persons who are not mathematicians, and all must in some degree possess and appeal to them whose occupations lead them to any considerations connected with measurement.

All who understand the term ratio must see that the ratio of two quantities does not depend on their actual magnitudes. If one line be to another in the ratio of 3 to 7, the halves, thirds, fourths, &c. of the two lines will have the same ratio; and the subdivision into aliquot parts may be continued without limit; thus the hundred-millionth part of one line will be to the hundred-millionth part of the other as 3 to 7. Ratio then always exists, as long as there is magnitude; but if magnitude should cease to exist, and if both lines should vanish, no idea of ratio can be formed. If however the diminution take place by continual subdivision, this evanescence of magnitude never takes place: for into how many parts soever a line may be divided, each part is a length, still subdivisible for ever.

The consideration here introduced is not an easy one at first, for there is a degree of smallness which evades the senses, and reason must come to their assistance. This makes a great difficulty, for many who think themselves rational geometers are not aware how much of their ordinary perception of geometrical truth is the consequence of what they see, not of what they deduce. All magnitude is relative, so far as the notion of great or small is connected with it; we know this when we stop to think, but we do not easily take it along with us in our thoughts; there is nothing absolutely great or small, but we are continually making an absolute greatness out of magnitude which is great compared with our own bodies, and an absolute smallness of that which is in the same sense comparatively small.



Take AO, an arc of a circle, A_2O its half, A_3O its third part, A_4O its fourth part, and so on; let the chords AO, A_2O, A_3O, &c. be drawn. The points A_1, A_2, A_3, A_4, &c. constitute a series continually approaching to O in position, but never reaching it, for no aliquot part of AO is absolutely nothing. Now it can be shown that A_xO, the chord of (A_xO) the xth part of the arc, will be nearer to a ratio of equality with (A_xO) the greater x is taken, so that any approach to equality may be attained and passed by making x sufficiently great. The beginner's notion is, almost invariably, that two small quantities must be nearly equal, because they are small; and the fallacy under which they proceed is the following:—quantities which are nearly equal to the same are nearly equal to one another; small quantities are all nearly equal to nothing, therefore small quantities are nearly equal to one another. The mistake here lies partly in the use of *nothing* as if it were a quantity, having all the properties of quantity, partly in the supposition that quantities which differ little must be nearly equal. If by differing little, be meant that the difference is trifling when compared with the quantities themselves, the notion is a good one: two microscopic animalculæ are nearly equal when they differ by a small portion of an animalcula, but if they differ by the size of a gnat, though their absolute difference is still small, compared with our usual standards, the larger is immensely greater than the other. But if the just notion of nearly equal be adopted, it is wrong to say that the chord and arc are nearly equal on account of their smallness, since their small difference may possibly itself be larger than one of them. And as to using *nothing* as a quantity in the fallacious syllogism above given, it must be remembered that, with reference to possibility of subdivision, any quantity, however small, is as distant from nothing as any other quantity, however great, is from infinity.

Nevertheless, as may be rationally shown, the chord and arc are the more nearly equal the smaller they are. The conception of this proposition may be aided as follows:—

however small a line may be, we may represent it by as great a number as we please, if we take the unit of measurement still smaller, and sufficiently smaller; now let the arc taken be the nth part of the radius; then if a unit be taken so small that the arc shall be represented by $24n^2$, the chord will be a fractional number extremely near to $24n^2-1$. Thus if the arc be one-thousandth of the radius, and a unit be taken to measure it which is its 24-thousandth part, so that the arc is 24,000, the chord will contain that unit a very small fraction more than 23,999 times. And if n be made still greater, the inequality will be made still less, being capable of being made a unit out of any number we may name, however great.

In the article LIMIT we should say that the limiting ratio of the arc and chord is unity; in INFINITE, that an infinitely small arc is equal to its chord. Newton's phrase was that the arc and chord are ultimately equal, or that their ultimate ratio is one of equality. He strives to guard this language as much as possible in the Scholium which terminates the first section, and from which we now quote.

'I have premised these lemmas, that I might avoid the tedium of long demonstration, with reductions *ad absurdum*, after the manner of the antients. Demonstrations are shortened indeed by the method of indivisibles.' [CAVALIERI.] 'But since this hypothesis is somewhat difficult, and the method is not thought very geometrical, I have preferred to make what follows depend upon the ultimate sums and ratios of vanishing quantities. . . . . I do not wish to be understood as using indivisibles, but divisible vanishing quantities; not sums and ratios of determinate parts, but limits of sums and ratios. . . . .

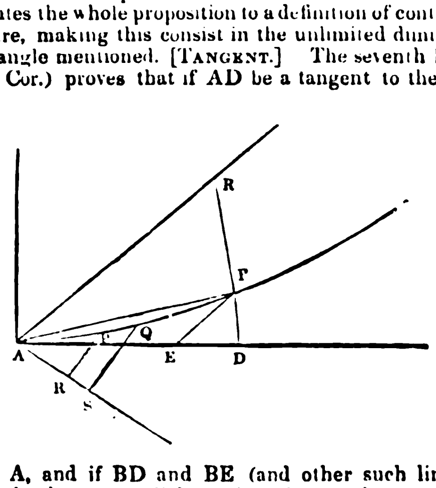
'It is objected that there is no ultimate proportion of vanishing quantities, because, before they have vanished the proportion is not ultimate, and after they have vanished there is no proportion. But by the same argument it could equally be contended, that there is no last velocity with which a body reaches the place where its motion stops; for before the body reaches its final position, it has not its last velocity, and when it reaches it, it has no velocity. And the answer is easy: by the last velocity I understand that which the body has, not before it reaches its last point and the motion stops, nor afterwards, but at the moment when it reaches, namely, that very velocity with which the body reaches its last position, and with which the motion ceases. And similarly, by the ultimate ratio of vanishing quantities, is to be understood the ratio of the quantities not before they vanish, nor after they vanish, but with which they vanish. Similarly the prime ratio of nascent quantities is the ratio with which they begin their existence (ratio quacum nascuntur). And the prime and ultimate sum is that with which (whether increasing or diminishing) they begin and cease. . . . It may also be contended, that if the ultimate ratios of vanishing quantities be given, the ultimate magnitudes will be given; and thus that every magnitude will consist of indivisible parts. . . . . But this objection proceeds on a false hypothesis. The ultimate ratios with which quantities vanish are not really the ratios of ultimate quantities, but the limits to which the ratios of quantities diminishing without limit perpetually approach, and which limits may be attained within any given difference, but can never be passed, nor even actually attained before the quantities are diminished in infinitum. The thing will be more clearly understood by speaking of infinitely great quantities. If two quantities with a given difference be increased in infinitum, the ultimate ratio will be given, that is to say, a ratio of equality, but the ultimate or greatest quantities of which this is the ratio will not therefore be given. In what follows therefore, if ever, thinking of making things more easily conceivable, I should talk of the last possible quantities, or of vanishing or ultimate quantities, do not understand thereby quantities of determinate magnitude, but think always of quantities diminishing without limit.'

This notion, whether of limiting ratios, of ultimate ratios, or of the ratios of infinitely small quantities, is a real and positive conception of our minds, but one of which, put it into what language we may, the mode of expression is liable to some objection. The ultimate magnitudes of the senses are not those of the understanding, but all our terms connected with the latter are derived from habits of thought matured by aid of the former. The ultimate arc of a curve which the eyes perceive is, to those eyes, really straight, all curvature being imperceptible. Indeed sensible straightness begins long before length vanishes. Continued reflection only will clear away the approximate truths of the senses, and enable the student to see how the ultimate truths of the theory of limits are to be established.

The first section of the Principia, consisting of eleven lemmas and the scholium from which we have quoted, opens with a lemma which should rather be the definition of the manner in which the word ultimate is used: and much objection has consequently been taken to it. 'Quantities,' says Newton, 'and the ratio of quantities, which constantly tend to equality during any finite time, and before the end of that time approach to each other within less than any given difference, become ultimately equal. If you deny it, let them be ultimately unequal, and let their ultimate difference be D, then they cannot approach nearer to equality than quantities having a difference D: which is against the hypothesis.' It is obvious that in this lemma Newton has a more decided opinion of the existence of an ultimate state of vanishing quantities, subject to all the relations of magnitude, than the expressions cited from the scholium would lead us to suppose; and the argument against those who would affirm ultimate *in*equality, is sound and conclusive. But those who would deny this lemma would oppose it on the ground that quantities which have vanished, and have ceased to be quantities, have neither ratio nor any relation of magnitude whatsoever, and the same opponents would deny inequality to such ultimate states as well as equality. A student who interprets Newton by his own subsequent expressions will consider this lemma as the definition of the sense in which *ultimate* equality is to be understood.

The second lemma asserts the ultimate equality of the area of a curve with the sum of the inscribed and of the circumscribed rectangles, and has been proved in the article AREA. This lemma confines itself to rectangles standing on equal subdivisions of the base. The third proves the same on the supposition that these subdivisions are unequal; and its four corollaries assert the same ultimate equality when the inscribed figures are bounded by chords and the circumscribed figures by tangents. The fourth lemma (with a corollary) proves that if the inscribed rectangles in one curve are (or ultimately become) in a given ratio to one another, each to each (it being supposed that the same number is inscribed in both), the curvilinear areas are themselves in the same ratio.

The fifth lemma is an assertion of the properties of similar figures, curvilinear as well as rectilinear, for which we refer to SIMILAR FIGURES. It appeals to a geometry supposed to be established and familiar; and it is one of the impediments to a learner of the present day in reading the Principia, that he must frequently be at a loss, when the difficulty occurs, to know whether he should look elsewhere for something more of the nature of preparation, or endeavour to conquer it by reflecting upon the position which stops him. The sixth lemma is of the same kind; it asserts that when a chord drawn from a given point of a curve diminishes without limit, the angle made by that chord with the tangent must diminish without limit, if the curvature be continuous. The proof is of that character which strongly assimilates the whole proposition to a definition of continuous curvature, making this consist in the unlimited diminution of the angle mentioned. [TANGENT.] The seventh lemma (with 3 Cor.) proves that if AD be a tangent to the curve



AB at A, and if BD and BE (and other such lines) be constantly drawn parallel to given lines; then, as B approaches to A, the ultimate ratio of any two of the set AE, AD, &c., the arc AB, and the chord AB, is that of equality: for a further consideration of this point, see TANGENT. The eighth lemma (with a corollary) proves that the ultimate forms of the triangles RAD and RAB (the latter whether bounded by the chord or the arc AB) are those of similar triangles: and the ninth proves that if any line AS (other than the tangent) be drawn from A, and PQ, RS be drawn parallel to any given line from points of the curve P and Q, the ultimate ratio of the curvilinear spaces APR, AQS, will be the duplicate ratio of the ultimate ratio of AR to AS.

In the tenth lemma (5 Cor. and Scholium) it is shown that the spaces described by a point acted on by a finite force (constant or variable) in different times from the beginning of the motion, are, when those times are diminished without limit, ultimately in the duplicate ratio of the times.

In the eleventh lemma (5 Cor.) it is shown that the subtense BD (or BE, &c.) is such that different subtenses drawn from different points of the curve are ultimately in the duplicate ratio of their arcs, or of the chords of these arcs, if the curvature be finite. [TANGENT.]

The study of the theory of ultimate ratios, as given by Newton, is desirable on several grounds. The mere acquisition of the language is a benefit; for subject as all terms in which the propositions can be expressed are to misapprehension, it frequently happens that the associations which one kind of language suggests are corrective of errors which another language has allowed, or even favoured. No student can be sure that his ideas on the subject are sound until, comparing together any proposition (as in DIFFERENTIAL CALCULUS) expressed by means of infinitesimals, limits, and ultimate ratios, the same proposition in the three different ways, he feels a perfect coincidence of meaning between the three statements, and that each expresses as much as, and no more, than the others. Again, the consideration of ultimate ratios puts vividly before the mind of the student who is used to the algebraical methods, a picture of the truth which is meant to be stated, and prevents his resting upon the abstract symbols of the Differential Calculus. For want of such an accompaniment to the latter study, many have found it repulsive, more, unintelligible, at least for a long time, and some have even never arrived at any rational comprehension of its meaning.

RATISBON (in German, Regensburg), the capital of the circle of the Regen, in the kingdom of Bavaria, is one of the most antient towns in Germany, having been built by the Romans, by whom it was called Reginum, Castra Regia, and subsequently Augusta Tiberii. In the second century it was already a place of trade. Under the Agilolfingers it was the capital of Bavaria, and after the deposition of the last duke of that line by Charlemagne, towards the end of the eighth century, it was governed, under the immediate protection of the German kings, by a Count or Grave, and, like other towns which carried on considerable trade, it received the denomination of a royal city. The bishopric is said to have been founded in 740. From 1663 to the dissolution of the German empire in 1806, it was the seat of the Diet.

Ratisbon is situated in 49° N. lat. and 12° 22′ E. long., in an extensive and fertile valley, on the south side of the Danube, opposite to its confluence with the Regen. The Danube here forms two small islands, called Oberwörth and Niederwörth, which are laid out in agreeable promenades. These islands are connected with each other and with the two banks of the Danube by a remarkable stone bridge, 1100 feet in length and 23 feet wide, which was built in the years 1135-1140, and connects Ratisbon with its suburb Stadt-am-Hof on the north bank. The town is surrounded with ramparts, but not capable of defence against an enemy. The ditches have been filled up. Most of the houses are built of stone, but they are very old-fashioned, and their great height adds to the gloominess of the streets, which are narrow and crooked, but cleanly and well-paved. The most remarkable buildings are the large antient town-house, containing the hall in which the German Diet held its sittings, the Gothic cathedral, St. Peter's church, the Lutheran church of the Holy Trinity, the palace of the Prince of Thurn and Taxis, the antient abbeys of St. Emmeran, Niedermünster, and Obermünster. The first abbey comprises a great number of buildings, resembling a little town, and has a library, a fine collection of paintings, and an excellent collection of mathematical and philosophical instruments, the new theatre, and the antient Jesuits' college. There are in all one cathedral and twenty-seven other churches and chapels, of which there are thirteen Roman Catholic and three Lutheran principal churches. Besides the library in the town-house, there are some other considerable libraries and collections of works of art; also a botanical society, a united Roman Catholic and Lutheran gymnasium, an ecclesiastical seminary, a school for the blind, and a school of design. There are extensive bleaching-grounds and celebrated breweries; and manufactories of leather, tobacco, wax candles, soap, cutlery, earthenware, porcelain, fire-arms, and carriages. The inhabitants carry on a considerable trade in salt, timber, corn, and their own manufactures, and do extensive business on commission. The population is about 21,000. Stein's Lexicon (1820), Hassel (1819), and Cannabich (1830) say that two-thirds are Roman Catholics and one-third Lutherans, which the relative number of churches seems to confirm; but Hörschelmann (1834) and the 'Conversations Lexicon' say the majority are Protestants. We believe the latter to be mistaken.

Near the city is a monument, erected in 1817, in honour of Kepler, who was born here, and on a rock on the banks of the Danube stands the Walhalla, a marble temple erected in honour of the great men of Germany. In 1809 there were great battles, for five days, between the French and the Austrians, near Ratisbon, in which the city suffered severely.

RATTLE is a term applied to a common agricultural weed, and derives its name from the dry parchment-like seed-vessels rattling, if shaken, when ripe. It grows a foot high, has narrow lanceolate serrated leaves, dilated and heart-shaped at the base, and a yellow ringent flower enclosed in a bladdery calyx. It is an annual, in many cases very common in bad pastures and meadows. We have in this country two species, the smaller and the larger; the former can scarcely be said to be injurious to the farmer, but the latter sometimes overruns corn-fields to such an extent as almost to destroy the crop, especially in parts of the country where the soil is peaty. Careful fallowing seems the only means of extirpating this kind of weed.

RATTLESNAKE. [VIPERIDÆ.]

RATZEBURG is a small principality belonging to the grand-duchy of Mecklenburg Strelitz, but entirely separated from it by Mecklenburg Schwerin, being situated between the latter and the territory of Lübeck, and the duchy of Lauenburg, which belongs to Denmark. The area is 1?5 square miles, and the population between 14,000 and 15,000. It is traversed by the river Trave, and is bounded on the west by the lake of Ratzeburg, by means of which, and of the Wackenitz, it has a constant communication with Lübeck for the exportation of timber, corn, pulse, flax, and cattle. The inhabitants are likewise much employed in the fisheries. They have paper-mills, lime-kilns, copper and brass founderies. Ratzeburg was formerly a bishopric, but was secularised in 1648, at the peace of Westphalia.

RATZEBURG, the chief town of the principality, belongs to the duchy of Lauenburg (with the exception of the part comprehending what is called the Domhof (the close) and the Palmhof, containing 36 houses, 250 inhabitants, the cathedral school, and the hospital, which belongs to Mecklenburg Strelitz), and is the seat of the government of the principality. [LAUENBURG.]

RAUHE ALP. [GERMANY.]

RAUCHWA'CKE (in Geology), one of the calcareous members of the zechstein formation of Germany, the equivalent of the magnesian limestone formation in England. It is either compact, or cellular, or dolomitic. Associated with gypsum and with beds called stinkstein, asche, zechstein, and kupferschiefer, it makes a series of five terms which may be classed and arranged in comparison with English types and names. This is done by Von Meyer, after Sedgwick, thus:—

German.	*English.*
Asche (friable marl), and Stinkstein (thin-bedded fetid limestone).	Thin bedded limestone of Knottingley.
	Coloured marls and gypsum.
Rauchwacke (limestone).	Yellow magnesian limestone.
Zechstein (limestone).	Compact limestone.
Kupferschiefer (copper-slate).	Marl-slate.

We may perhaps prefer to view the asche, stinkstein, and rauchwacke, as altogether only one feeble upper group, comparable with the upper laminated and cellular limestones of Knottingley, and the zechstein as equivalent to our yellow magnesian limestone, in which case the kupferschiefer is on the parallel of our marl slates (both full of fishes of the genus Palæoniscus).

(See Daubuisson's *Traité de Géologie*, vol. ii.)

RAVAILLAC. [Henri IV.]

RAVEE. [Hindustan.]

RAVELIN, a work constructed beyond the main ditch of a fortress, and in front of the curtain between two bastions. It usually consists of two lines of rampart, which meet in a salient angle on a line drawn perpendicular to and bisecting the curtain; and its form on the ground-plan may be seen at Q, *fig.* 1, Bastion, and at QQ, Fortification. Its profile, or the figure of a vertical section of its rampart, is similar to that of the enceinte. [Bastion, *Fig.* 2.]

The ravelin was probably first constructed in the place of the more antient barbacan by the Italian engineers of the sixteenth century, when, on account of the general employment of cannon in sieges, the antient towers and walls of masonry were either replaced or covered by ramparts of earth. Its original name, *rivellino*, indicates a derivation from *vegliare*, 'to watch;' and both by Maggi (1584) and Errard (1594), rivellino, or ravelin, and bastion, are used as the names of a work beyond the walls of a fortified place. In some cases the rivellino appears to have been merely a parapet of earth covering a small place of arms in which were stationed the men appointed to guard the head of the bridge leading from a postern to the counterscarp of the ditch; and a work of this kind, of a semicircular form, still exists on the exterior of the ditch on one side of Carisbrooke Castle. It can scarcely be doubted that a semicircular form was very frequently adopted for such parapets, and this circumstance may have given rise to the name of demi-lune, or half-moon, by which, even now, the ravelin is often designated. It ought to be observed however that Errard and other writers of that age apply the word ravelin to a work placed immediately in front of the salient angle of a bastion, where the counterscarp of the ditch (which is there in the form of a segment of a circle) constitutes the gorge of the work; and that the name of half-moon may, on this account, have been applied to the work, though its faces were rectilinear. A piece of fortification thus situated is now invariably called a counterguard; and the term ravelin, or demi-lune, is confined to the principal outwork in front of the curtain.

When the necessity of increasing the strength of fortresses by means of works beyond the enceinte, in consequence of the superior means employed in the attack, was strongly felt, the ravelin was made more capacious, and was provided with artillery; and, in order to prevent it from being taken by surprise, its ditch was enlarged, and the covered-way was continued on the exterior of the latter along both the faces of the work. Before the middle of the seventeenth century the ravelins were so small, that the exterior lines (the cordons) of their faces, if produced towards the rear, fell upon the curtain of the enceinte, and the lengths of the faces did not exceed 30 yards. Count Pagan then enlarged the works so that the produced faces fell at the shoulders of the bastions; but Vauban apparently, in what has since been denominated his first system, made the faces of the ravelins about 110 yards long, and directed them towards points on the faces of the bastions at 10 yards from the shoulders [Q, *fig.* 1, Bastion]. The magnitude of the work was then such as to render it capable of making a good defence: it covered the curtain and flanks of the enceinte, so that the enemy could not demolish their parapets by means of artillery in his distant batteries; and, one being placed on each front of the fortress, every two afforded not only a crossing fire on the approaches of the enemy towards the intermediate bastion, but they seriously impeded the formation of the counter-batteries on the crest of the glacis.

It was subsequently perceived that great advantages would arise if the faces of the ravelins were made still longer, and if they were directed to points at a greater distance from the shoulders of the bastions: by the first, a reverse fire, as it is called, might be directed from the angle of the work upon the enemy's lodgments on the glacis before the bastions: and by the other, the power of breaching the shoulders of the bastions by means of a battery on the glacis, before the salient angle of the ravelin, would be taken away from the enemy. At Landau and other places, Vauban, without increasing the lengths of the faces of the ravelins, directed their exterior lines to points at 20 yards from the shoulders of the bastions; while at Neuf Brisac he not only made the lengths of the faces above 120 yards, but he directed them to points at 30 yards from the shoulders. It should be observed however that at about 20 yards from the counterscarp of the main ditch he changed the directions of the faces, and made the portion between this point and the ditch nearly perpendicular to a line joining the salient angles of the collateral bastions, as in the work Y, Fortification; by which means the second advantage, above mentioned, was lost. The intention of Vauban in thus giving flanks to the ravelin was that, by a fire from thence, the difficulty of forming a lodgment on the glacis in front of the bastion might be increased so much as to oblige the enemy to take the ravelin before he could execute such lodgment: but experience has shown that this is not the fact; for the flanks, as he has formed them at Neuf Brisac, having no work to cover their prolongations, are enfiladed, and their guns dismounted, at an early period of the siege.

Cormontaigne (1736) greatly improved the ravelin by giving it the figure represented at QQ, Fortification, making the length of each face about 130 yards, and directing that line to a point between 20 and 30 yards from the shoulders of the bastions. He reduced the terreplein, or space between its parapet and the counterscarp of the reduit Y, to 27 feet, in order that the enemy might not find room on it to form batteries for the purpose of breaching the reduit; and the faces being unbroken in direction, not only are the shoulders of the bastions covered, but the enemy is prevented from breaching any part between the shoulder and the retrenchment X. The gorge, or rear line, of the ravelin, instead of coinciding with the general direction of the counterscarp of the main ditch, is made parallel to the curtain of the place, in order to take away a part of the terreplein which would have been seen by the enemy from his counter-batteries on the glacis of the bastion. It appears that Cormontaigne wished to give the ravelins a greater length of face than that which has been mentioned, and that he was prevented from doing so through the opposition of his cotemporaries. For the advantages to be derived from very salient ravelins, see Fortification, p. 376, col. 2.

The only change which has since been made in the position of the ravelin is that which was proposed by Bousmard (1803), and followed in the works executed by order of Napoleon about Alessandria (1807). It consists in placing the work beyond the glacis of the enceinte, at the foot of which glacis its ditches terminate; the covered-way and glacis before the bastions being continued uninterruptedly along the exterior of the main ditch. It thus becomes impossible to breach the enceinte by artillery placed anywhere on the glacis of the ravelin; and, when the direction of each face is broken, as that engineer recommended, the probability of the rampart being enfiladed is much diminished. It might perhaps be objected that the ravelin so detached is liable to be attacked at the gorge; but if the covered-way of the ravelin be made to join that of the collateral bastions, and if its flanks, or those of the reduit, are disposed so as to allow a fire of musketry to be kept up in the direction by which the enemy must approach the gorge, this danger may be obviated.

The relief of the ravelin, or its elevation above the level of the ground, should be two or three feet less than that of the enceinte, in order that the defenders of the curtain may be able to direct a plunging fire into the work when it is occupied by the enemy. But if in the interior of the ravelin there should be a reduit, this last ought, for the same reason, to have less relief by two or three feet than the curtain; and then, in order to afford a plunging fire from the reduit into the ravelin, the latter should be two or three feet lower than the former. It ought however to have a command of six or seven feet over the glacis in its front, that the fire of its artillery may not annoy the defenders on the banquette of its covered-way. Therefore, if the command of the enceinte over the ground is 18 feet, and that of the glacis is seven feet, the differences between the heights of the enceinte and reduit, and of the reduit and ravelin, may be two feet successively.

RAVEN. [Corvidæ, vol. viii., p. 68.] We subjoin a cut of the head and foot of this species as belonging to an eminently omnivorous form.

Head and Foot of Raven.

RAVENGLASS. [CUMBERLAND.]

RAVENNA, LEGAZIO'NE DI, a province of the Papal State, is bounded on the north by the province of Ferrara, on the west by that of Bologna and by the grand-duchy of Tuscany, on the south by the province of Forli, and on the east by the Adriatic. The area is about 935 square miles, and the population 149,000. (Neigebaur; Calindri.) The eastern part of the province, which lies near the Adriatic, is low and marshy, but the western or inland part, which stretches to the foot of the Tuscan Apennines, in the neighbourhood of Imola and Faenza, is healthy, well cultivated, and thickly inhabited. The chief products of the country are corn, wine, silk, hemp, and cattle. A considerable quantity of sea-salt is derived from the lagoon of Cervia, which belongs to the government, and is a source of revenue. The principal towns of the province are RAVENNA, FAENZA, IMOLA; Cervia, a small town, in an unhealthy situation, near the sea-coast, has about 1000 inhabitants; Brisighella, near the borders of Tuscany, has about 7000 inhabitants, including its territory; and Castel Bolognese, a bustling town, in a fertile district, has about 4000 inhabitants.

The province of Ravenna is crossed by numerous streams, which rise in the Tuscan Apennines, and flow in a north-east direction to the Adriatic. The principal are—the Santerno, which flows by Imola; the Senio; the Lamone, which flows near Faenza; the Montone, which enters the sea below Ravenna; and the Ronco, which joins the Montone above its mouth.

The province is divided, for administrative purposes, into three districts:—Ravenna, Faenza, and Imola. A road leads from Faenza to Tuscany by ascending the valley of the Lamone, and, after crossing the Apennines above Marradi, descends into the valley of the Sieve, north of Florence.

RAVENNA, situated in 44° 26′ N. lat. and 12° 12′ E. long., is an antient city, once a seaport, but now five miles from the sea, which has receded all along this coast, owing to the accumulation of sand thrown up by the waves, and of the alluvial earth brought down by the rivers. The town is now in the midst of a marshy desolate plain covered with ruins, which recalls to the mind of the traveller the Campagna of Rome. Between Ravenna and the sea is the 'Pineta,' or forest of pines, which extends about fifteen miles in length along the sea-coast, and which has been noticed by Dante, Boccaccio, Dryden, and Byron (*Don Juan*, c. iii.). Ginanni has written a description of the various kinds of pines and other trees of which the forest consists: *Storia civile e naturale delle Pinete Ravennati*, 4to., Rome, 1774, with plates.

Ravenna is an archbishop's see, and the residence of the legate of the province: it has a college, and civil, criminal, and commercial courts. The population is about 18,000 (Calindri.) The cathedral, built in the fourth century, but since that time almost completely rebuilt, retains several sculptures and other remains of its early age: the baptistery, detached from the church, is still in its original state. The church of Santa Vitale was built by Justinian in imitation of Santa Sophia of Constantinople: it has some handsome pillars of granite, and a large mosaic, in good preservation, representing the emperor Justinian with his courtiers, and his empress Theodora attended by her ladies. The mausoleum of Placidia, daughter of Theodosius, and sister of Honorius, and that of her second husband Constantius, are in the vaults beneath. Ravenna has many Byzantine monuments and recollections, which give it the appearance of a Greek rather than an Italian city. The church of St. John the Baptist, was built by Placidia, as well as that of St. John the Evangelist, with its altar, made of porphyry and other valuable marbles. The mausoleum of Theodoric, which is outside of the town, has a monolithic dome, nearly 100 feet in circumference, which has been transformed into a church, called Santa Maria Rotonda. There is a portico, supported by eight granite columns, and other remains of the splendid palace of Theodoric, which was inhabited by his successors the Exarchs. Charlemagne stripped it of its ornaments, which he carried into France. The church of St. Apollinaris in Classe, so called because it was built on the site of the old port, is a magnificent structure, raised also by Theodoric, with twenty-four large columns, each of a single piece of marble, which were brought from Constantinople; and a fine mosaic, representing a view of Ravenna in the sixth century, with numerous figures of saints. The great altar is made of porphyry, verde antico, and oriental alabaster; and the pulpit, which is of marble, is of curious workmanship. Ravenna, next to Rome, is the city of Italy which abounds most with valuable and rare marbles from Greece, Asia, and Africa. The church of St. Apollinaris contains the tombs of many of the old archbishops of Ravenna, and a series of their portraits.

The other remarkable churches of Ravenna are—Santa Maria in Porto, built in the sixteenth century; St. Romuald, which now belongs to the college of Ravenna; Santa Agatha; St. Theodore; St. Domenico; St. Michele, which was transformed under the French into a fish-market; and St. Francis, which has the tombs of the Polenta lords of Ravenna. All these churches are adorned with rich marbles, valuable paintings, mosaics, and sculptures. The church of St. Lorenzo, outside of the town, built by the emperor Honorius, was destroyed in 1553, and the marble columns were carried to Rome.

The public library of Ravenna contains 40,000 volumes and 700 MSS., among which are a MS. of the plays of Aristophanes, written in the tenth century, of which Bekker made use for his edition, London, 1829. There is also a cabinet of antient medals and inscriptions, and a gallery of paintings.

The mausoleum of Dante, who died at Ravenna, was raised in the fifteenth century, by Bernardo Bembo, a Venetian podesta, and father of Cardinal Bembo: it has been repaired several times. The names of Honorius, Placidia, Theodoric, Narses, Justinian, and Dante are all associated with Ravenna.

The antient town of Classis, the port of Ravenna, which stood two or three miles south of the city, was destroyed in the year 728 by Luitprand, king of the Longobards: it is now a marsh, four miles distant from the sea. (See the antient topography of the coast about Ravenna, in Bertoldi, 'Memorie del Po di Primaro,' Ferrara, 1785.) Ravenna is 18 miles north-east of Forli, and 30 miles north-west of Rimini. A road leads from Ravenna to Rimini along the shore of the Adriatic, passing by Cervia and Cesenatico.

Ravenna is said to have been originally a town of the Umbri. It was afterwards possessed by the Boii, and formed part of Cisalpine Gaul. It is not particularly noticed in Roman history till the time of the Empire, when the port of Ravenna became one of the two great stations for the Roman fleet, Misenum being the other. Tiberius surrounded Ravenna with walls, of which the gate, or arch, called 'Porta Aurea,' is a remnant. But it was after the separation of the Eastern and Western empires that Ravenna attained its greatest importance. The harbour became the chief means of communication between the two empires; and several emperors of the West, Honorius I., his sister Placidia, and her son Valentinianus III., made Ravenna their place of residence. Afterwards Glicerius, Nepos, Orestes, and other ephemeral puppets, who succeeded each other on the throne of the West, resided likewise at Ravenna. After the fall of the empire, Theodoric made Ravenna the capital of his kingdom, and he greatly embellished the town. When Narses, the general of Justinian, having overthrown the kingdom of the Goths, A.D. 553, was appointed by the emperor, exarch or governor-general of Italy, he fixed his residence at Ravenna, which continued under his successors to be the centre of the Imperial administration in Italy, till Astolphus, king of the Longobards, took Ravenna, A.D. 752. In 755, Pepin, having defeated Astolphus, obliged him to give up Ravenna and the district called the Pentapolis to the see of Rome. But the cession was merely nominal, and the archbishops of Ravenna appear to have had the civil administration of the town and its territory, which was still called the Exarchate for a long period under the Carlovingian dynasty. [PAPAL STATE.]

In the middle ages, Ravenna, like the other towns of North Italy, was a republic, and, like them, it had its factions, which were headed by two powerful families, the Traversari and the Polenta. In the latter part of the 13th century the Polenta drove away the Traversari, and usurped the supreme power. Guido da Polenta, lord of Ravenna, was the father of the beautiful Francesca, who married Lancelot Malatesta, lord of Rimini, and, being detected by her husband in adultery with his brother Paul, was killed by him together with her paramour. This catastrophe has furnished Dante with the subject of one of his most affecting episodes (*Inferno*, v.). Dante in his banishment was the friend and guest of Guido da Polenta, who protected him in his old days and bestowed on him funeral honours after his death. The successors of Guido remained in possession of Ravenna till the year 1440, when the Venetians took it. The Venetians kept it until 1509, when it was taken from them by the French under Louis XII. In 1512 the French army under Gaston de Foix, duke of Nemours, fought a desperate battle near Ravenna against the Spanish and Papal troops. The French won the battle, but lost their commander, and soon after they were compelled to retire from Italy. Nearly 20,000 men lay dead on the field of battle, where a small marble pillar was raised on the banks of the river Ronco, and is still called 'the pillar of the French.' By the treaty of Bologna in 1530, Ravenna and its territory were given up to the pope. (Rubeus Hieronymus, *Historiarum Ravennatum Libri XI.*, fol. Venice 1590.)

RAVENSCROFT, THOMAS, a composer and editor much esteemed at the commencement of the seventeenth century, was born in 1592, educated in St. Paul's choir, and admitted to the degree of Bachelor in Music, by the university of Cambridge, it is supposed, when only fifteen years of age. In 1611 he printed a collection of twenty-three part-songs, under the title of *Melismata, Musical Phansies*, &c., in which is his justly admired four-voiced song, 'Canst thou love and lie alone?' In 1614 appeared his *Brief Discourse*, &c., another collection of twenty part-songs, to which is prefixed a discourse or essay on the old musical proportions, a vain endeavour to rescue them from the neglect into which they had deservedly fallen. In 1621 he made some atonement for this absurd and abortive attempt, by publishing 'The whole Book of Psalms, &c. composed into four parts by sundry authors, to such several tunes as have been and are usually sung in England, Scotland, Wales, Germany, Italy, France, and the Netherlands.' Among the 'authors' appear the names of Tallis, Morley, John Milton (father of the poet), &c. Many are by Ravenscroft, who, had he only produced St. David's, Canterbury, and Bangor tunes, would have ensured the respect and gratitude of his country. The work contains a melody for each of the hundred and fifty psalms, many newly composed, and all harmonised by the above-mentioned persons. (*Supp. to Mus. Lib.*) This, we believe, is the first collection of the kind that had appeared, and, judging from the specimens that have come under our view, it is a most valuable work. [PSALMODY.] Tradition ascribes to Ravenscroft the merit of having been compiler of two other works, similar in character to the *Melismata*—namely, *Pammelia* and *Deuteromelia*, both well known to musical antiquaries, highly valued by them, and now exceedingly rare: and the tradition receives support from an allusion in the 'Apologie' to his 'Brief Discourse,' to 'Harmonies by divers and sundry authors,' formerly published by him, the errors in which, he says, are 'corrected in this (i.e. *The Discourse*) *fourth* and last work.' The *Pammelia*, comprising one hundred pieces, is dated 1609; the *Deuteromelia*, containing thirty-two, bears the same date. A selection from the four above-named secular works was privately printed in 1822, for the use of The Roxburghe Club, by the Duke of Marlborough, who unhesitatingly ascribes the *whole* to Ravenscroft, though it might have been seen at a glance that this composer was author of but a few, while he may have been editor of all.

RAWITSCH. [POSEN.]

RAY. [LIGHT.]

RAY, JOHN, or WRAY (as he at one time spelt his name), who may be considered as the founder of true principles of classification in the vegetable and animal kingdoms, was the son of a blacksmith, and was born at Black-Notley near Braintree in Essex, on the 29th of November, 1627. He received a good education, being sent first to the grammar-school at Braintree, and afterwards to the university of Cambridge, where he entered at Catherine Hall, but subsequently removed to Trinity College, of which he was elected a fellow in 1649, together with Isaac Barrow. At the age of twenty-three he was appointed Greek lecturer, and two years afterwards mathematical tutor to his college. He was also private tutor to several gentlemen of rank, and among others to one who possessed a kindred spirit to himself, and whose name afterwards became closely associated with his own in the paths of science, Francis Willughby. Ray was always fond of the study of natural history, but it is recorded by his biographers that the circumstance which chiefly gave rise to his cultivation of the science of botany (in which he afterwards became so distinguished) was an illness, for the removal of which he was recommended to take frequent exercise out of doors. Being compelled to remit his drier studies, he collected and investigated the different wild plants which he met with in his walks about Cambridge, and in 1660 published a 'Catalogus Plantarum circa Cantabrigiam nascentium,' 1 vol. 8vo., which he says took him ten years to compile.

During his residence at the University he travelled over the greater part of England, Wales, and Scotland, in the pursuit of botanical and zoological information, and was generally accompanied in these excursions by his friend and pupil Mr. Willughby. At the Restoration he took orders, but never held any church preferment, nor performed regular parochial duty; and two years afterwards he was obliged to resign his fellowship in consequence of the passing of the Act of Uniformity, to which he could not conscienciously subscribe. After leaving the University he resided chiefly with Mr. Willughby at Middleton Hall in Warwickshire, and devoted the remainder of his life solely to the pursuit of natural history. In 1663 he embarked for the Continent with Mr. Willughby, where they remained for three years travelling through the Low Countries, Germany, Italy, Switzerland, and France; and collecting information respecting the animals and plants which inhabit these different countries. Willughby attended chiefly to zoology, and Ray to botany. An account of this tour was published by Ray in 1673, 1 vol. 8vo. In 1667 he was elected a fellow of the Royal Society, to the Transactions of which learned body he contributed some valuable papers. In 1672 he had the misfortune to lose his friend Mr. Willughby, who died at the age of 37, leaving him guardian to his two sons (the younger of whom was afterwards created Lord Middleton) and a legacy of 60*l.* per annum. After superintending the education of Mr. Willughby's children for some time at Middleton Hall, he removed to Sutton Coldfield, in Warwickshire, and then to Falkbourn Hall, Essex, and lastly he settled in 1679 at Black-Notley, his native place, where he remained till his death, which took place January 17, 1704-5, at the age of 77. In 1673 he married a young lady 24 years younger than himself, by whom he left three daughters. Ray was not more respected for his scientific acquirements than for his benevolence, which was combined with high moral and religious worth.

Ray left many works, among which the botanical and zoological hold such a conspicuous place in the history and literature of those sciences, that they demand a brief notice. His first publication was the 'Catalogue of the Plants growing in the neighbourhood of Cambridge,' which we have already mentioned. This work contains a description of 626 species arranged alphabetically, and accompanied with the synonyms of the principal botanical authors who had preceded him: it is curious, from its being the first production of a man who afterwards attained to such great celebrity, and it exhibits traces of those singular powers of observation which he afterwards so eminently displayed. In the preface, which in this, as in most of his other works, contains much interesting matter, he describes the difficulties which he had to overcome in the prosecution of his botanical studies, the principal of which was the want of some acknowledged guide which he might follow in the determination of species. Many curious notes are introduced into this catalogue, which have not only reference to the structure and properties of the plants themselves, but to other parts of natural history, particularly entomology, to which he appears to have already paid considerable attention: among other facts he observed the hermaphroditism of the snail. A supplement to this catalogue appeared in 1663, and a second in 1685.

In 1682 appeared his 'Methodus Plantarum Nova,' 1 vol. 8vo., in which he proposed a new method of classifying plants, which, when altered and amended, as it subsequently was by himself at a later period, unquestionably formed the basis of that method which under the name of the system of Jussieu is universally received at the present day. In the formation of the principal groups into which he divided the vegetable kingdom, Ray derived his characters sometimes from the fruit, sometimes from the flower, and sometimes from other parts of the plant, as each in its turn seemed to offer the most strongly marked points of distinction. He first proposed the division of plants into dicotyledons and monocotyledons. 'Floriferas dividimus,' he says, 'in *dicotyledones*, quarum semina sata binis foliis anomalis seminalibus dictis quæ cotyledonum usum præstant è terra exeunt, vel in binos saltem lobos dividuntur quamvis eos supra terram foliorum specie non efferant; et *monocotyledones*, quæ nec folia seminalia bina efferunt nec lobos binos condunt.'* He extended these divisions both to trees and herbs, stating that palms differ as much in this respect from other trees, as grasses and lilies do from other herbs. Though he made these great discoveries and improvements, Ray obstinately continued in the old error of separating woody from herbaceous plants, or trees from herbs, and he held a long controversy with Rivinus on this point: he even went so far as to state that one of these divisions might be distinguished from the other by the presence of buds, which he says are only developed in woody plants. To him is due however the honour of the discovery of the true nature of buds, for he says that they are points at which new annual plants spring up from the old stock, but he stopped short in his discovery in not extending them to herbaceous plants. In the first edition of the 'Methodus' he formed 25 classes, taking the woody plants first, which he divided into trees and shrubs. In this system he fell into many errors, one of the most glaring of which, as he himself afterwards observed, was the separation of the different species of corn from the other grasses. He subsequently altered this, and revised the whole arrangement, making 34 groups instead of 25; many of which are almost exactly the same as are adopted by botanists of the present day under the name of natural orders. The following table, taken from the second edition of his 'Methodus,' published in 1703, will give an outline of his system:—

Herbaceous plants and undershrubs not bearing buds	Imperfect or without visible flowers	1. Submarine plants.
		2. Funguses.
		3. Mosses.
		4. Capillary.
	Perfect or flowering plants:—	
	Dicotyledones	5. Stamineous, *i.e.* Apetalous.
	Flower compound	6. Planipetalous, milky.
		7. Discoid with pappus seed.
		8. Corymbiferous.
		9. Capitale.
	Flower simple:—	
	With 1 naked seed	10. Monospermous.
	With 2 naked seeds	11. Umbelliferous.
		12. Stellate.
	With 4 naked seeds	13. Rough leaved.
		14. Verticillate.
	With many naked seeds	15. Polyspermous.
	Seeds coated with pulp	16. Pomiferous.
		17. Bacciferous.
	In several distinct vessels	18. Multisiliquous.
	In a single vessel	19. Monopetalous and D[i]petalous plants.
		20. Siliquose.
		21. Leguminose.
		22. Pentapetalous.
	Monocotyledones, or grass leaved:—	
	Bearing flowers	23. Bulbous or not bulb[ous].
	Without proper flowers	24. Stamineous grasses.
		25. Anomalous plants.
Trees or shrubs bearing buds.	Monocotyledones: with arundinaceous leaves	26. Palms
	Dicotyledones:—	
	Flowers remote from fruit	27. Coniferous.
	(Monœcious or diœcious)	28. Not coniferous.
	Flowers contiguous to fruit:—	
	Fruit	29. Umbilicated.
		30. Not umbilicated.
		31. Dry, not siliquose.
		32. Siliquose.
	Flower	33. Papilionaceous.
		34. Anomalous plants.

This arrangement was too far in advance of the k[now]ledge of the day, and the consequence was that it was [not] appreciated or adopted by his contemporaries and im[me]diate successors, who, instead of improving the arrange[ment] so ably sketched out, set about establishing others on a[rti]ficial principles, all of which are rapidly sinking into obli[vion] while the principles of Ray are tacitly admitted, and m[any] of his fundamental divisions adopted in that beautiful [but] still imperfect natural system which has been formed b[y the] labours of Jussieu, Brown, De Candolle, Lindley, [and] others.

While he made these important improvements in cla[ssifi]cation, this great botanist did not neglect the stu[dy of] species; his 'Catalogus Plantarum Angliæ' first app[eared] in 1670, arranged alphabetically, and has been the bas[is of] all subsequent Floras of this country. A second edition [ap]peared in 1677, and in 1690 he published a third, ent[itled] 'Synopsis Methodica Stirpium Britannicarum,' which [is] arranged according to his natural system. Another ed[ition] of the 'Synopsis' came out in 1696, and it was again rep[ub]lished by Dillenius in 1724. This work, of which the e[di]tion of 1696 is the best, is very accurate. Ray examin[ed] every plant described in the work himself, and investiga[ted] their synonyms with great care.

In 1694 he published 'Stirpium Europæarum extra Br[i]tannias crescentium Sylloge.' This work contains a descrip[tion] of all those plants which he had himself collected on [the] Continent, as well as many which had been described [by] others. The synonyms are here very exact.

His largest botanical work was a general 'Historia Pl[an]tarum,' the first volume of which came out in 1686, f[ol.], second appeared in 1688; and a third, which was sup[ple]mentary, in 1704. In this vast work he collected a[nd ar]ranged all the species of plants which had then been [de]scribed by botanists; he enumerated 18,625 species. Ha[ller], Sprengel, Adanson, and others speak of this work as t[he] the produce of immense labour, and as containing m[uch] learning and acute criticism; but from its nature it was [of] course principally a compilation.

Ray made many researches in vegetable physiology. H[e] published a very interesting paper in the 'Philosophi[cal] Transactions' (No. 68), on the mode of ascent of the sa[p], and we find many observations on the structure and fu[nc]

* 'Methodus Plantarum,' edit. 2, p. 2.

tions of plants scattered through his various works. In the first volume of the 'Historia Plantarum' he collected together, under the title of 'De Plantis in Genere,' all the principal discoveries which had been made on the structure and properties of plants by Cesalpin, Grew, Malpighi, and others, as well as by himself; so that he thus published by far the most complete introduction to botany that had then appeared.

In zoology Ray ranks almost as high as in botany; and his works on this subject are even more important, as they still in a great measure preserve their utility. Cuvier says, that 'they may be considered as the foundation of modern zoology, for naturalists are obliged to consult them every instant, for the purpose of clearing up the difficulties which they meet with in the works of Linnæus and his copyists.' Mr. Willughby, at the time of his death, left to his friend Ray the task of arranging and publishing the various materials which he had collected for an extensive work on the animal kingdom. Ray exhibited as much zeal as fidelity in the execution of this trust, for he might have called the works partly his own without much injustice, as he had assisted in the first collection of the materials, and had the entire task of arranging and classifying them; besides which, it is easy to observe, as Cuvier has remarked, that the histories of plants and animals are both written by the same hand.

The 'Ornithologia' of Willughby, which was the first part of the work that appeared, was published in 1676, one vol. fol., with seventy-seven plates. An English translation of it, by Ray, appeared the following year. The remaining part, which is the most complete, was the 'Historia Piscium,' and did not come out till 1686, 2 vols. fol. These works contain a great number of new species of birds and fishes, which had been discovered by Willughby and Ray in Germany and Italy, as well as those which had been previously described. Cuvier says, 'the fishes of the Mediterranean are described with rare precision, and it is frequently easier to find species in Willughby than in Linnæus.' Many of the figures in these works are original, and very good.

Ray published several works of his own on zoology. He undertook to form a classical arrangement of the whole animal kingdom, as he had of the vegetable; and, in 1693, he published his 'Synopsis Methodica Animalium, Quadrupedum, et Serpentini Generis,' one vol. 8vo. Similar volumes on birds and fishes were also prepared by him, but were not published till after his death, by Dr. Derham, in 1713. The two last are principally abridgments of the great works published under the name of Willughby. He also left a history of insects, which was likewise published by Dr. Derham, at the expense of the Royal Society, and contains an appendix on beetles, by Dr. Lister. This last work is remarkable for the numerous and accurate descriptions of insects which it contains, part of which, he says, had been prepared by his friend Mr. Willughby. The author here rejects the theory of spontaneous generation. The most important character of the zoological works of Ray is the precise and clear method of classification which he adopted. The primary divisions of his system were founded on the structure of the heart and organs of respiration. His arrangement of the classes of quadrupeds and birds has been followed by many naturalists. Both Linnæus and Buffon borrowed largely from the works of Ray. Buffon extracted from Willughby's 'Ornithology,' almost all the anatomical part of his history of birds; and Cuvier says that the 'Dictionnaire d'Ichtyologie,' by Daubenton and Haüy, in the 'Encyclopédie Méthodique,' consists in great part of translations from Ray's works on fishes.

In addition to his numerous scientific writings, Ray composed several works on divinity and other subjects: the best known of these are, 'A Collection of Proverbs,' which came out in 1672, and went through several editions; 'The Wisdom of God in the Creation,' 1690, which also had an extensive sale; 'A Persuasion to a Holy Life,' 1700; and the 'Physico-Theological Discourses concerning Chaos, the Deluge, and the Dissolution of the World,' 1692.

(*Life*, by Dr. Derham; Haller's *Bibl. Bot.*; *Life*, by Cuvier and Du Petit Thouars, in the *Biog. Univer.*; and *Life*, by Sir J. E. Smith, in Rees's *Cyclop.*)

RAYED or RADIATED ANIMALS, *Radiaria* or *Radiata*, Lamarck's name for a class of invertebrate animals, which he divides into the *Radiaires Molasses* and the *Radiaires Echinodermes*. Of the former, the *Medusæ* are an example [PULMOGRADA]; the latter consist of the ECHINODERMATA. The class is treated of under the article STELLIRIDIANS.

RAYMOND, Counts. [LANGUEDOC.]

RAYMUND LULLY. [LULLY.]

RAYNA'L, GUILLA'UME THOMA'S FRANÇOIS, born in 1711, at St. Geniez, in the province of Rouergue, now the department de l'Aveyron, studied in the Jesuits' College at Pézénas, and took orders as a priest. He afterwards left the Jesuits, and came to Paris, where he was made assistant-curate of the parish of St. Sulpice, in 1747. It is stated, in the 'Biographie Universelle,' that he was dismissed from the service of that parish in consequence of simoniacal practices; among others for exacting illegal fees for performing the office of the dead. He next turned to literary pursuits, and having made himself acquainted with several influential men, he became editor of the 'Mercure de France.' He also wrote 'Histoire du Stathouderat,' 12mo., 1748, which has been reprinted several times: the last edition is that of Paris, 1819, with additions. It is a superficial work, and written in a declamatory style. His 'Histoire du Parlement d'Angleterre' is equally superficial and inaccurate. From these and his 'Anecdotes Littéraires,' 'Anecdotes historiques, militaires, et politiques,' and other similar light works, he derived a considerable profit. At the same time Raynal speculated in mercantile affairs, and, it is said by Désessart, in his 'Siècles Littéraires de la France,' that he employed capital in the slave-trade. At Paris he frequented the society of Helvetius, Holbach, and Madame Geoffrin.

In 1770 he published his great work, by which he is chiefly known, 'Histoire Philosophique des Etablissemens des Européens dans les deux Indes,' 4 vols. 8vo., La Haye, without the author's name. The work was reprinted several times, both in France and out of France, with additions by the author; and although many passages were written in a very violent tone against monarchy, and especially the French monarchy, and against Christianity, the French government allowed the book to circulate undisturbed. In the meantime Raynal travelled in Holland and England, and collected fresh materials for his work, of which he published a new and enlarged edition at Geneva, 10 vols. 8vo., 1780, with his name and his portrait.

The French authorities now took notice of the book. In May, 1781, the parliament of Paris condemned it to be burned by the hand of the executioner, and ordered the author to be arrested and his property sequestrated, but his friends in office gave him timely notice to quit France and to place his property in safety. Raynal repaired to Spa, where a young Belgian addressed to him a laudatory epistle, 'La Nymphe de Spa à l'Abbé Raynal,' which drew upon the author the censure of the prince bishop of Liege, the sovereign of the county. Raynal replied by another letter, in which he abused the clergy, and bishops in particular, in the most virulent manner. He had long since openly renounced his priestly character, and spoke of himself as 'having been once a priest.' From Spa he repaired to Saxe-Gotha, and from thence to Berlin, where he sought an audience of Frederic the Great, who, being displeased at some passages of his work which reflected upon himself, declined seeing him for a long time, until at last, Raynal having made a written application, Frederic gave him an audience at Potsdam, made him sit down, and talked to him about his former histories of the Stathouderat and of the parliament of England. Raynal eagerly said that he had written more important works since. 'I am not acquainted with them,' replied Frederic drily, thus putting an end to further remarks on that topic. (Thiébault, *Mes Souvenirs de Vingt Ans de Séjour à Berlin.*) Frederic afterwards wrote to D'Alembert concerning his interview with Raynal, who, he said, spoke much about the wealth, the resources, and the power of nations, and in so positive a manner, 'that, in listening to him, I almost fancied that I was listening to the voice of Providence.' In 1787, Raynal was allowed to return to France, but not to Paris. His friend Malouet, who was intendant-general of the navy at Toulon, received him hospitably in his house. Raynal marked his residence in the south of France by several acts of beneficence and philanthropy, as he had done previously during a journey in Switzerland. Droz, in his 'Histoire du Regne de Louis XVI.,' says: 'Raynal was a good-hearted man, easy and mild in his manners; but the obscurity in which his former works had left his name irritated his vanity

Fearing that the valuable materials which he had collected in his principal work on the trade of the East and West Indies might not be sufficient to attract public attention to himself, he interspersed his narrative with republican disquisitions, licentious descriptions, and contradictory assertions, which he lived to regret. It is well known that the most reprehensible passages of this compilation belong to Diderot, but Raynal shared the responsibility by adopting them as his own.' Turgot, in a letter which is found in the 'Mémoires de l'Abbé Morellet,' thus characterises Raynal's history:—'Whilst I admired the talent of the author, I have been somewhat shocked at the inconsistency of his ideas, and at seeing so many conflicting paradoxes put forward, and all supported with a like warmth, a like eloquence, and a like fanaticism. He is at times immoral, like Helvetius, and at others a rigorist, like Richardson; now he speaks with enthusiasm of mild virtues, and now he extols with an equal warmth savage courage and lust; he pretends to detest slavery, and yet he thinks there must be slaves; he reasons badly in physics, badly in metaphysics, and also often in politics. You gather no fruit from his book: you perceive that the author is a very clever man, possessed of extensive information, but who has no fixed ideas, and is carried along by an enthusiasm worthy of a young rhetorician.'

Raynal's work is a fair sample of that species of composition which was known in the last century by the name of 'philosophical history,' the specimens of which have been greatly multiplied, especially in France, and have largely contributed to lead astray the minds of the people on subjects of morality and politics by confounding their ideas of right and wrong. It is one of those works which, by glowing descriptions of wrongs inflicted in ages past, accumulated as it were in one view, are apt to excite feelings of indignation and revenge against whole classes of living persons who are innocent of those evils, but who are considered as the representatives of the former perpetrators, such as kings, nobles, and priests, and which, by stimulating all the passions and removing all checks upon self-gratification, are calculated to loosen the bonds of society; leaving to the chances of futurity the task of reconstructing something on the desolation which they have helped to effect.

The distribution of Raynal's work is as follows:—Book i. is on the discoveries of the Portuguese, and their conquests in and trade with India; ii., on those of the Dutch; iii., of the English; iv., of the French; v., of the Danes, Swedes, and other northern nations; vi., vii., and viii., Conquests of the Spaniards in America; ix., of the Portuguese in Brazil; x. to xiv., Colonization of the West India Islands; the eleventh book treats of the slave-trade; xv. to xviii., Settlements of the French and English in North America; book xix. consists of general reflections on the state of society, on religion, government, war, commerce, agriculture, manufacture, population, taxation, public debt, the fine arts, sciences, philosophy, and morality, terminating with a summing up of the good and the evil derived to Europe from the discovery of America. [COLONIES.]

Raynal's work has been the subject of many strictures, refutations, and corrections. A Virginian wrote 'Recherches Historiques et Politiques sur les Etats Unis de l'Amerique Septentrionale,' 4 vols. 8vo., Paris, 1788. A Dutchman published, in 1791, one volume of extracts from Raynal's book concerning the commerce of the Dutch colonies. The duke of Almodavar extracted and translated into Spanish the part concerning the colonies of Spain, and refuted several fallacies. An anonymous writer published 'Observations sur plusieurs Assertions extraites littéralement de l'Histoire Philosophique des établissement des Européens dans les deux Indes,' 8vo., Amsterdam and Paris, 1776.

When the first symptoms of the French Revolution showed themselves, Raynal was elected by the city of Marseille as their representative in the states-general. He declined the honour on the plea of old age; but the fact was that his opinions had undergone a great change. In December, 1790, a letter appeared in the papers, purported to be addressed by Raynal to the National Assembly, expressive of his altered sentiments on political subjects. This however was disavowed by Raynal's friends: but on the 31st of May, 1791, Raynal did address an eloquent letter to Bureau de Puzy, president of the National Assembly, in which, after drawing a gloomy sketch of the state of France, of the persecutions of the clergy, of the inquisitorial power exercised against opinions, of the disorders and violence of every sort which were daily perpetrated by mobs with impunity, and all in the name of liberty, he stated his regret that 'he was one of those who, by expressing in his works a generous indignation against arbitrary power had perhaps been the means of putting weapons into the hands of licentiousness and anarchy.' This letter, being read publicly by the president, occasioned a violent storm in the Assembly. Roederer called the president to order for reading the letter. ('Moniteur,' 31st May, 1791.) Journals and pamphlets vied with each other in abusing Raynal as a renegade and a dotard. Raynal however remained quiet in the neighbourhood of Paris; he passed unmolested through the period of terror; and he died in March, 17[illegible], at the house of a friend at Chaillot. Just before his death the Directory had named him member of the National Institute, and his 'éloge' was read by Lebreton at one of the first sittings of that body.

A new edition of Raynal's 'History' was published at Paris in 11 vols. 8vo., 1820-21, with a biographical notice and reflections on the works of Raynal, by M. A. Jay.

The following works have been erroneously attributed to Raynal: 1, 'Inconvénients du Célibat des Prêtres' (by the Abbé Gaudin); 2, 'Des Assassinats et des Vols Politiques sous le Nom de Proscription et de Confiscations' (by Servan).

RAZOR-SHELL, the vernacular name for the shells of some species of the genus *Solen*. [PYLORIDEA, p. 146.]

RAZZI, CAVALIERE GIOVANNI ANTONIO, called **IL SODOMA**, an eminent painter, was born about the year 1479, according to some, at Verceil in Piedmont, and as stated by others at Vergelli, a village near Siena. It is certain however that he received the right of citizenship at the latter place. He was instructed, according to Vasari, by Giacomo dalle Fronte, but he chiefly formed his principles by an attentive study of the works of Leonardo da Vinci. M. Périès, in the 'Biographie Universelle,' observes that his flesh-colours, his style of chiaroscuro, and other qualities inherent in the old Milanese school and in that of Girolamo Giovenone, who flourished at Verceil, during the earlier years of Sodoma, leave traces of the manner of that master, especially in the works which were executed in the earlier period of his career of celebrity. Among his earliest performances were the pictures he painted in 1502, at Monte Oliveto, representing the history of S. Benedetto. He was employed at Rome, in the pontificate of Julius II., to decorate part of the Vatican; but his works, with those of some other artists, not being to the taste of his holiness, were removed to make way for the frescoes of Raffaello. Some grotesques however from his hands were preserved. In the Chigi Palace, now called the Farnesina, are some of his pictures, representing the history of Alexander the Great, the most noted of which is the Marriage of Roxana, which were executed by order of Agostino Chigi, and which Mr. Fuseli considers to possess much of the chiaroscuro though not the dignity and grace of Leonardo da Vinci, and to be remarkable for beauties of perspective and playful imagery. At Siena he painted many works. The Adoration of the Magi, which is in the church of S. Agostino, resembles the style of Leonardo da Vinci, and some amateurs prefer the Scourging of Christ, his chef-d'œuvre, which is in the convent of S. Francisco, to the same subject by Michael Angelo; nor is the Swoon of St. Catherine of Siena, painted in fresco, in one of the chapels of S. Domenico, unworthy of the pencil of Raffaello. The St. Sebastian, in the gallery at Florence, is supposed to be painted from an antique torso. M. Périès also mentions a picture of the Sacrifice of Abraham, painted for the cathedral of Pisa, which was in the Louvre in 1814, and was returned to Tuscany in 1815, in which, although the light is distributed in too small masses and somewhat scattered, the forms exhibit great knowledge of art, and there is an admirable expression of truth in the figures

He is said by Lanzi to have frequently painted in a hurried manner, without any preparatory study, especially in his old age, when, reduced to poverty at Siena, he sought employment at Pisa, Volterra, and Lucca; but still, though careless of excellence, Sodoma never painted badly, and in all his pictures the traces of an able artist are visible; and Mr. Fuseli observes, when alluding to the same circumstance, 'in all his works we trace the master-hand, which, in spite of negligence, performs with power.' Vasari seems to have been a systematic opponent of Sodoma, and gene rally styles him a buffoon, 'but,' says Lanzi, 'Giovio has written of Razzi in a different manner; when speaking of the death of Raffaello, he subjoins: "plures post pene grandi varietate arcum exsuperunt, et in his Sodoma Vercellensis." He who objects to the testimony of this eminent scholar, will receive that of a celebrated painter. Annibale Caracci, passing through Siena, said, 'Razzi appears a master of the very highest eminence and of the greatest taste, and (speaking of his best works at Siena) few such pictures are to be seen.'

He seems to have had many pupils, the principal one of whom was Bartolommeo Neroni, generally called Maestro Riccio. Sodoma died in the year 1554, and is placed by Lanzi in the second epoch of the Sienese school. (Lanzi, *Storia Pittorica*, i. 300; *Biographie Universelle*; Pilkington's *Dictionary*, by Fuseli; Bryan's *Dictionary*.)

RE, in Music, the name given by the Italians and French to the second note of the diatonic scale, and generally throughout Europe to the second of the syllables used in SOLMIZATION.

RE', or RHE', ILE DE. [CHARENTE INFÉRIEURE.]

READING, the county town of Berkshire, situated in the hundred of Reading, but with separate jurisdiction, on the river Kennet, just above its junction with the Thames, 38 miles in a direct line west of St. Paul's, or 42 miles from the General Post-office by Brentford, Hounslow, and Maidenhead.

The first mention of Reading is in the year 871, when it was occupied by the Danes, who had thrown up an intrenchment between the Kennet and the Thames, to defend the tongue of land on which the town stands. They repulsed an attack of the West Saxons, under their king Ethelred and his brother Alfred, but quitted the town towards the close of the year. In A.D. 1006 it was burnt by the Danes, who destroyed an abbey of nuns, on the site of which a new abbey was erected by Henry I., who was buried here. In the civil war of Stephen and Maud, the town and castle changed hands more than once. It is supposed that the castle was demolished soon after that time. In the following reigns the kings frequently resided at Reading, and parliaments were held here. On the dissolution of the abbey, the buildings were appropriated as a royal palace. In the civil war of Charles I. Reading was made a parliamentary garrison; but Henry Marten, the governor, with the garrison, fled on the approach of a party of royalist cavalry (November, 1642), and the town was garrisoned by the king. In April, 1643, the Parliamentarians, under the Earl of Essex and General Skippon, besieged the town, and took it, after a faint resistance. The Royalists, under Prince Rupert, who had attempted to relieve it, were repulsed, at Caversham Bridge, near the town. Sir Arthur Aston, who had the command of the garrison, was wounded, and Colonel Fielding, who took the command, was condemned to death for the surrender, but pardoned. After the first battle of Newbury (September, 1643), the town was again occupied by the king, who left a garrison under Sir Jacob Astley, but in May, 1644, the Royalists quitted the town, which was finally occupied by the Parliamentarians. Reading suffered severely from being so long a garrison town. In the Revolution of 1688, the troops of James II. occupied the town; a slight skirmish took place here, and the king's forces speedily retired.

The town lies partly between the Kennet and the Thames, partly on the south side of the Kennet; it comprehends the three following parishes:—

	Area in Acres.	Population in 1831.
St. Giles . .	480	4740
St. Lawrence .	340	4048
St. Mary . .	1260	6798
	2080	15,595

The town altogether is very irregularly laid out. The parish of St. Lawrence, which is on the north-east side of it, occupying the point of land at the junction of the Kennet with the Thames, is probably as much covered with buildings as ever it will be, the unoccupied part consisting of low marshy meadows along the bank of the Thames; it contains the market-place, and two of the best streets in the town for business. The parishes of St. Mary on the west, and St. Giles on the south-east, contain portions of the trading part of the town. A large portion of the poorer classes reside in St. Mary's. St. Giles contains the residence of most of the gentry and persons of independent fortune. It is the favourite part of the town for building on, and several new streets and squares have been laid out along the London road. The town is well paved, and lighted with gas, and amply supplied with water from the Kennet. The houses are in general substantial, and built of brick; but there are some old ones of lath and plaster, with high gables. St. Lawrence's church appears to have been considerably repaired in 1434, but there are some portions of the original structure of Norman character; it consists of a nave and north aisle, separated from each other by a row of octagonal pillars, supporting five elliptical arches with ogee mouldings, and a chancel. There is a fine tower at the west end, of perpendicular character, and of chequered flint-work; it has a peal of ten bells. St. Mary's church consists of a nave, south aisle, a small north aisle, and a chancel: it was rebuilt about 1551, chiefly from the materials of the abbey church, then pulled down; it has a tower of similar character to that of St. Lawrence, but not equal to it. A large part, if not the whole, of the exterior part of the church is of chequered work. St. Giles's contains little that is remarkable. The town-hall is a modern building, over a part of the free-school; and there is a building termed (for what reason is not known) 'the oracle,' erected by Mr. John Kendrick, a great benefactor to the town, early in the seventeenth century, for the employment of the poor; the principal gateway, which is the most striking portion, is of mingled Gothic and Grecian architecture. As the river Kennet has a divided channel, there are many bridges; that over the main stream, in Duke Street, is a handsome stone bridge of one arch, with balustrades. There are some ruins of the abbey, especially one of the gates, and also some interesting remains of the abbey mill.

The trade of the town is considerable. There was anciently a large manufacture of woollen cloth, but it has become extinct. Some silk ribands and galloons are woven, and some floor-cloth and sail-cloth is made. There are iron foundries, breweries, and yards for boat-building. Trade is carried on in corn, seeds, malt, timber, bark, hoops, wool, cheese, and beer. There are markets on Wednesday and Saturday, the latter chiefly for corn; and four yearly fairs, one a large cheese-fair. The Kennet is navigable to the Thames, and the Kennet and Avon canal affords a water-communication with the west of England. The Great Western railway passes the town, and the main road from London to Bath and Bristol runs through it.

Reading claims to be a borough by prescription; the earliest known charter is of 37 Henry III., A.D. 1253. The corporation, by the Municipal Reform Act, consists of six aldermen and eighteen councillors; the town is divided into three wards. The spring assizes, and the Epiphany, and occasionally, though rarely of late years, the Michaelmas sessions for the county, are held here; and there are quarter-sessions for the borough, a court of record for causes not exceeding 10*l.* in amount, and a court leet, holden by the corporation as the lords of the manor. Petty-sessions are held here weekly for the division. There is a small borough gaol, altogether unfit for its purpose; and a county gaol, of very defective construction, so as to preclude the carrying into effect of many arrangements which the good discipline of the prison requires.

Reading is one of the polling-stations for the county. Two members of parliament are returned by the borough. It has possessed the right of election from 23 Edward I.; it was a scot and lot borough. The number of electors in 1835-6 was 977.

The living of St. Giles is a rectory, of the clear yearly value of 522*l.*, with a glebe-house; that of St. Lawrence is a vicarage, of the clear yearly value of 276*l.*, with a glebe-house; and that of St. Mary a vicarage, of the clear yearly value of 661*l.*, with a glebe-house. There is a chapel-of-ease in St. Mary's parish, and there are several dissenting chapels and a Catholic chapel in the town. Reading is in the archdeaconry of Berks, which the Ecclesiastical Commissioners have proposed to transfer from the diocese of Salisbury to that of Oxford.

There were in the borough, in 1833, two infant-schools, with 193 children; thirty-five day-schools or boarding and day schools, with 720 boys, 406 girls, and 20 children of sex not mentioned; three day and Sunday schools, with 502 scholars in the week and 651 on Sundays; and sixteen Sunday schools, with 698 boys and 630 girls. One of the day-schools is a free grammar-school, of which the late Dr. Valpy was for many years master. Several of the other schools are supported, at least in part, by endowments or subscription.

There are a public library and news-room, called the Reading Institution, a subscription news-room, a small theatre, and baths. There are several almshouses, and a dispensary.

REAL ESTATE. [PROPERTY.]

REALEJO, a seaport on the Pacific, in Central America, in the republic of Nicaragua, and in the department of Leon, in 12° 30′ N. lat. and 87° 7′ W. long. The harbour is formed by a small bay, at the entrance of which are two islands, called El Cardon and El Castanon. Vessels enter the harbour by the strait which separates these two islands. The harbour is spacious and safe, and has good anchoring-ground. The town is built on the northern shores of an inlet near the bay: it contains a population of less than 3000, but if that of the neighbouring village of Chinandego is included, it hardly falls short of 15,000. The inhabitants are chiefly merchants and persons occupied in ship-building, for which the neighbouring forests supply abundance of timber. Ship-building is a large branch of industry, and there are docks for that purpose. The commerce with the other republics of South America is considerable. The principal articles of trade are cacao, indigo, sugar, timber, mahogany, cedar-wood, tar and pitch, sail-cloth, and hides. Realejo may be considered as the port of the town of Leon, which is only about twelve miles distant, and connected with it by a carriage-road, the whole intervening distance being nearly on a level.

(Juarros, *Statistical and Commercial History of Guatemala*, translated by Baily; and Haefken's *Central America*.)

REALGAR. [ARSENIC.]

REALISTS. [NOMINALISTS.]

REAPING (or cutting the corn when it is ripe) is one of the most important operations of harvest. It requires many hands to accomplish it in proper time, so that the corn which is ready for the sickle may not be too ripe and shed, nor the fair weather be allowed to pass before all the corn is secured in barns or stacks. The labourers who are required all the year for the common purposes of husbandry seldom suffice for the harvest, especially on extensive farms, and recourse is usually had to the assistance of mechanics and artisans from the neighbouring towns and villages where the population is considerable, or labourers are induced by good wages to come from a distance. As the harvest is later in those parts of every country which have a more northern situation, or are higher above the level of the sea, bands of reapers from these come to assist in the harvest of those tracts whose produce is earlier. To encourage the annual return of so desirable assistants, every encouragement is given them, not only by wages, but also by food and drink, and amusements after the toil of the day. Thus the time of harvest is a time of rejoicing both to the labourers and the master.

The common reaping-hook, or sickle, with which the corn is usually cut, is one of the oldest instruments of husbandry; and the goddess Ceres was generally represented by the antients with a sheaf of corn and sickle in her hand. In reaping with the sickle, a portion of the stems is collected with the left hand, and held fast; while the sickle in the right hand is inserted below the left, taking the stems in its semicircular blade, and cutting them through by drawing the sickle so as to act as a saw, for which purpose the edge is finely serrated in a direction from the point to the handle. The heads of the corn, with the upper part of the straw, are then laid on the ground in quantities which may readily be collected into a sheaf. Practice soon gives dexterity to the reaper; and he finds it more expeditious to cut small quantities in succession until he has filled his hand, than to attempt to cut through a large handful at once. Severe wounds are often inflicted on the fingers of the left hand by beginners, even to the loss of a finger; but this soon makes them cautious and expert. The division of labour is introduced with advantage amongst a band of reapers. A certain number cut the corn, while others follow to gather the sheaves; some only preparing the bands, and others tying them and setting up the sheaves into stooks or shocks, which usually consist of ten or twelve sheaves. The smaller the sheaves are, the less injury the corn sustains in a wet harvest; as the moisture in a thick sheaf does not so readily evaporate. Hence it is the interest of the farmer to see that the reapers do not make the sheaves too large. In many places there is a regular measure for the circumference of a sheaf, which should never exceed thirty inches. The bands are made by taking two small handfuls of the cut corn, and crossing them just below the ears into a knot. The sheaf is then pressed with the knee, and the band drawn tightly around it. The ends are twisted together like a rope, and inserted under the band, which effectually fastens it. This operation is soon learnt, and is done very rapidly. The sheaves should be so tied that there may be no danger of their falling loose when pitched into the cart or stacked, without being so tight as to prevent the moisture in the straw from evaporating. They should not be tied too near the ears, but rather nearer to the butt. The sheaves, when tied, are placed two and two on the butt-ends, with the ears leaning against each other: sometimes they are placed in a circle, all the ears being together, and the butts slanting outwards: a sheaf is then opened, by inserting the hand into the middle of the ears, and reversed over the tops of the preceding, forming a cone, and covering all the other ears, while it hangs down around them. In this position they will bear much rain without injury. It is a good practice to place the shocks across the furrows between the stitches or lands, so as to allow the air to circulate more freely around them. In this case four or five sheaves are placed in a row, leaning against as many in a parallel row; and two sheaves, being opened, are reversed over them to protect the ears. Whatever be the mode adopted in reaping the corn, the same kind of sheaves are formed, and set up in shocks.

Wherever the sickle is used for reaping, the straw is cut at a certain height from the ground, and the remainder forms a long stubble, which is usually mown at leisure after harvest, and carried into the yard for litter; but in the neighbourhood of large towns, where straw is sold at a good price, or exchanged for stable dung, it is important that as much as possible of it should be cut with the corn. This has introduced the practice called fagging, and sometimes bagging, the origin of which provincial expressions is not well known. The instrument used for this purpose partakes of the nature of a scythe, as well as of a reaping-hook. It is shaped like a sickle, but is much larger and broader; and instead of being indented like a saw, it has a sharp edge like a scythe, which is renewed when blunt by means of a stone or bat. The fagging-hook cuts the straw close to the ground by a stroke of the hand; and its curved form is only useful in collecting stray stems, and holding a certain quantity of them between it and the left hand of the reaper when he makes up a sheaf. A certain quantity is cut towards the the standing corn, the left hand pressing it down at the same time. When as much is thus cut as would make half a small sheaf, the reaper comes backwards, cutting in a direction at right angles to the first, and rolling together the two parts, which he carries in the bend of his hook and places on the band which has been prepared for him. A full-sized sheaf is usually composed of two cuttings. Two men will fully employ a third to make bands for them, to tie up the sheaves, and set them up. This method of reaping is laborious, on account of the stooping required to cut near the ground. The Hainault scythe, which has been described in most agricultural works, does the work better, and with less fatigue. It is in fact a fagging-hook, not quite so curved, of which the handle is longer, and placed at an angle with the plane of the blade. It requires some practice to give the proper swing to it by a peculiar motion of the wrist; but when this is once acquired, a considerable saving of labour and time is effected. Many attempts have been made to bring it into use in England; but, from the obstinacy of the labourers, or the want of perseverance in the masters, without much success. A better instrument however on extensive farms is the cradle-scythe, which, in the hands of an expert mower, will do more work and more effectually secure all the straw than any other instrument.

The objection to the great barn-room required for so much straw is obviated by the practice of stacking the corn in the open air on proper stands to keep it dry and out of the reach of vermin. The additional trouble in threshing is not so great as that of mowing or raking the stubble, which is generally deferred till half of it is lost by decomposition by the air and moisture. The advantage of mowing extensive crops is clearly shown in a paper in the fourth number of the 'Journal of the Royal Agricultural Society of England,' by Mr. Rodwell of Alderton Hall, Suffolk, who has found by experience that the crop of wheat which was mown by the scythe and tied up in sheaves was fully as soon fit to be carried as that which had been reaped. When the saving of time is considered as well as the saving of expense, there seems to be no doubt that on an extensive farm the scythe is far preferable to the sickle for cutting every kind of grain. Barley and oats are usually mown and carried without tying them into sheaves, but this is a slovenly and wasteful practice: by means of the cradle-scythe they may be mown so regularly as to be readily tied into sheaves; and the additional expense will be fully compensated by the saving of all the corn which, being on the outside of the stack, is lost by the depredations of small birds.

Beans are usually reaped by the sickle, the stems being too strong and too wide apart to admit of the scythe. Where it can be done conveniently, without the soil adhering too much to the roots, it is better to pull them up, and tie them in bundles with straw bands, or tar-twine, which will be found both a convenient and economical method.

Peas are generally reaped by means of two large hooks similar to the fagging-hooks, one of which is held in each hand; and the stems, which are generally much interwoven, are partly cut and partly torn from the roots, and so rolled up into a small bundle laid loose in order that it may dry. Tares are reaped in the same way.

The expense of reaping corn is considerable, especially where the population is scanty. In the eastern counties men are engaged for the whole harvest, which, in favourable weather, is supposed to be completed in a month. During this time they have their usual daily wages, with or without food, and a certain sum besides, as harvest money. In other districts the labourers reap the corn by the acre, with a certain allowance of beer, or money instead of it. The price of fagging in Middlesex and within 20 miles around London varies from nine to twelve shillings per acre, according to the crop, and if it is lodged, as much as fifteen shillings is often paid, including beer. The use of the scythe considerably diminishes the expense, as fewer labourers are required.

There have been many attempts to introduce machinery for reaping corn. Some of the inventions were ingenious and promised well, but none, when put to the test, answered the expectations formed. The various inclinations of the straws prevent any regular mode of cutting. A patent is at this moment obtained for an invention for reaping corn and mowing grass, of which the particulars have not yet been published: whether it will be more successful than its predecessors remains to be proved. The principle of most reaping-machines is that of a revolving edge to cut the straw, and a drum to lay the cut corn down regularly. Wherever the corn is laid or lodged, it is evident that no machine can collect straws lying in every imaginable direction and interwoven with each other. Till some better invention appears, the scythe will probably be found the cheapest and most expeditious instrument for reaping the corn. [HARVEST.]

REASON, according to the common notion, is the highest faculty of the human mind, by which man is distinguished from brutes, and which enables him to contemplate things spiritual as well as material, to weigh all that can be said or thought for and against them, and hence to draw conclusions, and to act accordingly. A man may therefore be said to possess reason in proportion as he actually exercises that power, that is, reasons and acts according to the conclusions or results at which he has arrived. In such expressions as 'We have reason to believe such an account,' or 'He has no reason to be dissatisfied,' the word 'reason' does not signify the mental power itself, but the conclusion or result of the process of reasoning, in contradistinction to motives, which are never the results of mental operations, but merely outward circumstances by which our actions are influenced.

Thus far reason is of a purely practical nature, and Kant therefore divided reason (if we may venture to translate his word *Vernunft* by the English word *reason*) into practical and theoretical. The latter, which is also called pure, ideal, or transcendental reason, is, according to him, the mind's power of producing ideas *à priori* from its own resources, or the power of conceiving things and their attributes which lie beyond the sphere of our experience, such as infinity, the absolute, God, the supreme good, &c. How far our knowledge of these things can extend is shown in the work of Kant, entitled 'Kritik der reinen Vernunft,' or 'Criticism of Pure Reason.' Reason, in its practical acceptation, forms ideas *à posteriori*, in as far as it derives them from a consideration and comparison of the phenomena of the external world, endeavours to discover unity in variety, and traces all phenomena to one source, a supreme reason, of which human reason is only a reflex.

Schelling defines reason to be the identity of the subjective and the objective, that is, the identity of the power which knows and that which it knows, which includes the knowledge of this identity. As the original identity, says he, exists in God, or is God, reason is a direct knowledge or an intellectual perception of God, of whom no indirect knowledge is possible. Hence God and reason are essentially of the same nature; they are identical: God is in reason, and reason is in God.

(G. M. Klein, *Beiträge zum Studium der Philosophie als Wissenschaft des All*., p. 219, &c. There are some good remarks on this subject in S. T. Coleridge's *Aids to Reflection*, p. 187, &c.)

RÉAUMUR, RENÉ-ANTOINE FERCHAULT DE, was born at Rochelle in 1683. He was brought up to the law, but being much attached to scientific pursuits, and possessing an independent fortune, he gave up his profession and went to Paris in 1703, where he determined to devote his life to his favourite studies. In 1708 he read some geometrical observations before the Academy of Sciences, which were so well received that he was admitted a member at the age of 24. He belonged to that learned body for fifty years, and contributed a vast number of interesting papers to their Memoirs.

The chief objects of his attention were the improvement of the arts and manufactures of his country, and natural history. In 1711 he made some experiments relative to the manufacture of cordage, and he proved that the strength of a cord is less than the sum of the strengths of the threads of which it consists; whence it follows that the less a rope is twisted, the stronger it is. In 1715, while examining the process of colouring artificial pearls, he discovered the nature of the singular substance which gives the brilliancy to the scales of fishes, and he investigated the mode of formation and growth of these scales. He also made some researches of a similar kind on the development of the shells of testaceous animals. When describing, in 1715, the turquoise-mines which he discovered in Languedoc, and the means which are employed to colour these stones, he found that the substances of which these gems consist are portions of the fossil teeth of an extinct animal since named the mastodon.

The most important of Réaumur's labours in the department of the arts were the experiments which he made on the manufacture of iron and steel. He published his researches on this subject in a separate work (those which we have before mentioned appeared in the Memoirs of the Academy), entitled 'Traité sur l'Art de convertir le Fer en Acier, et d'adoucir le Fer Fondu.' He here described the process of making steel, which was then unknown in France (that metal being solely obtained from abroad), and he made his discovery public, for which national benefit the Regent duke of Orleans settled on him a pension of 12,000 livres. He also discovered the art of tinning iron, which was likewise unknown in France. During his experiments on metals Réaumur first observed that these substances in passing from a fluid into a solid state have a tendency to assume certain definite crystalline forms. Among his other useful labours he greatly improved the manufacture of porcelain in France. He also made a number of experiments on artificial incubation, which has been practised from time immemorial in Egypt. He endeavoured to introduce the art into common use in France, but was not successful, owing principally to the greater coldness of the climate than in Egypt. In 1711 he discovered a species of mollusk from which a purple dye might be prepared analogous to the purple of the ancients.

In general physics the name of Réaumur is celebrated from the thermometer which he invented in 1731. He took the freezing and boiling points of water as two fixed points, and then divided the interval into 80 degrees, the freezing point being zero. The centigrade thermometer now in more general use in France was only an improvement on Réaumur's, the interval between the freezing and boiling points being divided into 100 instead of 80 degrees. [THERMOMETER.]

Though many of the researches which we have mentioned (most of which will be found in the Memoirs of the Academy, together with many papers on other subjects by the same author) were very useful and important, yet his labours in the field of natural history were much more novel and interesting. In 1710 he described the means by which many shell-fish, echinodermata (sea-stars), and other mollusks and zoophytes, execute their progressive movements, and in 1712 he observed the curious phenomenon of the reproduction of the claws of lobsters and crabs.

Of all the works of Réaumur, 'the most remarkable,' as Cuvier says, 'and those which cannot fail to be studied with the most vivid interest by those who wish to have just ideas of nature, and of the marvellous variety of means which she employs to preserve the most fragile of her productions, and those which are in appearance the least capable of resistance,' are his 'Mémoires pour servir à l'Histoire des Insectes,' of which 6 volumes 4to. appeared between 1734 and 1742. Cuvier adds, 'The author here carries to the highest point his acuteness of observation in the discovery of those instincts, so complicated and so constant in each species, which maintain these feeble creatures. He unceasingly excites our curiosity by new and singular details. His style is a little diffuse, but clear, and the facts which he relates may always be depended on.' While collecting materials for this work we find it recorded that he kept numerous insects of all kinds in his garden, for the purpose of observing their habits and instincts. Unfortunately this work is not finished, and the 7th vôlume, which came into the hands of the Academy of Sciences after the death of the author, was left in such an imperfect state that it was not capable of publication. The six volumes which were completed include all the winged insects, except the crickets (*gryllus*), grasshoppers, and beetles. The first two volumes comprise the various kinds of caterpillars, with a description of their forms, mode of life, metamorphoses, &c., as well as the different insects which attack them or live parasitically within them. The third volume includes the clothmoths, aphides, &c. The fourth embrances the gall insects and the various two-winged flies. The fifth contains the history of bees, and Réaumur made many interesting discoveries concerning the habits of these curious insects, which however have been greatly added to since by the labours of Huber and others. The smaller communities of wasps, hornets, &c., together with an account of the different kinds of solitary bees, occupy the sixth and last volume, which is one of the most curious of the whole.

Réaumur formed a large collection of objects of natural history, of which Brisson was the conservator, and the principal materials for that naturalist's works on quadrupeds and birds were collected from it. Many of Buffon's plates were also taken from objects in his museum, which, after his death, went to the 'Cabinet du Roi.' Réaumur passed a quiet retired life, and his private history is unmarked by any important incident. He is said to have died from the effects of a fall which he received while riding in the country. His death took place in October, 1757, in his 75th year. (*Life*, by Cuvier, in *Biog. Univ.*)

REBEC (*Rebec*, Fr.), a musical instrument of the violin kind, which had three strings tuned in fifths, played on by a bow. This, which has long been in disuse, was small in size, something between the modern violin and the dancing-master's *kit*, or pocket-fiddle, and seems to have been the primitive violin. Laborde says that it was the favourite instrument of the minstrels; and the *ribible*, of which Chaucer and Gower speak, is supposed to have been the rebec. It was much used at festive entertainments. Milton, in *L'Allegro*, mentions it as the 'jocund rebec.'

REBELLION. [SOVEREIGNTY.]

REBOLLE'DO, BERNARDINO, COUNT OF, a distinguished Spanish officer and writer, and one of the heroes of the latter period of the thirty years' war in Germany, was born of illustrious parents at Leon, the capital of the province of that name, in 1597. From his early youth he embraced the profession of arms, and joined the Spanish army of Italy, where he so much distinguished himself as to obtain soon after (1622) the command of a galley, with which he assisted in the taking of Port Maurice and the castle of Ventimille from the Genoese. After this he served in the army, and was present at the taking of Nice (1626) and the storming of the fortress of Casal, where he was severely wounded. In 1632 he commanded a considerable body of Spanish infantry in the Low Countries. Having, in 1636, received orders from his government to march to the assistance of the emperor Ferdinand II., who was closely pursued by the Swedes, he succeeded in extricating that monarch from his perilous situation, and was by him rewarded with the title of Count of the Germanic Empire and the government of the Low Palatinate. At the conclusion of the war, Philip IV. rewarded Rebolledo's services by appointing him his ambassador to the court of Denmark; and rendered signal service to the king of Denmark when Charles Gustavus marched his army across the frozen sea and bombarded Copenhagen. Though a zealous Catholic, Rebolledo felt for the royal house of Denmark a kind of personal devotion, which he seized every opportunity of manifesting in his writings. He had early evinced some talent for poetry, and his taste for military and political affairs had not prevented him from successfully cultivating literature. He had whilst in Germany composed a sort of didactic poem on the art of war and state policy, entitled 'Selvas Militares y Politicas,' which he afterwards published at Copenhagen in 1652, 16mo. But it was not until his mission to that capital, when he had attained the age of maturity, that Rebolledo found leisure to prosecute with assiduity his poetic studies. He seems to have taken particular interest in the history and geography of Denmark, a compendium of which he put into verse, which was printed at Copenhagen, under the title of 'Selvas Danicas,' 1665, 4to. After a residence of several years at the court of Denmark, Rebolledo was recalled to Madrid, where he was soon after appointed president of the Board of War in the council of Castile. He died in 1676, in the eightieth year of his age. Besides the two above-mentioned works, Rebolledo wrote—1, 'La Constancia victoriosa y Trinos de Jeremias,' Colonia (Copenhagen), 1665, 4to., being a paraphrase of the Book of Job and the Lamentations of Jeremiah; 2, 'Selvas Sagradas,' Ib., 1657, and Antwerp, 1661, 4to. [These are sundry poems on moral and religious subjects, and chiefly translations of the Psalms, where the author displays some poetic feeling, though much disguised under the pedantic forms of the Gongorine school.]; 3, a play entitled 'Amor despreciando Riesgos' (Love dreads no Danger), possesses considerable interest. Rebolledo was particularly successful as a writer of madrigals, some of which are so good as to remind the reader of the best times of Spanish poetry, which in Rebolledo's time was fast on its decline. His lighter poems appeared at Antwerp, 1660, 16mo., under the title of 'Ocios' (Leisure Hours). An edition of Rebolledo's works was collected in his lifetime, and appeared at Antwerp, 1660, in vols. 4to. But the best and most complete is that of Madrid, 1778, 4 vols. 4to.

REBUTTER. [PLEADING.]

RECAPTION. [REPLEVIN.]

RECAPTURE. [PRIZE.]

RECEIPT is when, in an action between others, a stranger whose rights or interests may be compromised by the result of the suit, prays to be received as a party to it for the purpose of defending them.

This was a remedy partly existing at common law, partly created by statute. The object of it was to prevent the tenant of the freehold, or the termor, &c. respectively, by means of an action collusively brought against him, from defeating the rights of the termor, or the tenant of the freehold, &c. by offering no real defence to the action. In such case the party sought to be thus defrauded was allowed to come and defend his own rights himself. (2 *Inst.*, 233; Com. *Dig.* tit. 'Receipt.') Something analogous to this has been provided by stat. 11 Geo. II., c. 19, § 11, 12, under which, in case of ejectment against a tenant, the landlord, heir, mortgagee, &c. is allowed to come in and defend in his stead. [EJECTMENT.] In actions of a personal character, by the statute of Interpleader, 1 & 2 Will. IV., c. 58, a defendant who has no interest in the matter for which he is sued, may substitute in his place a third party who claims an interest in it.

In its more general and popular sense receipt means a written discharge of a debtor on the payment of money due. When given for sums greater than five pounds, it must be stamped. The amount of the stamp duty varies with the sums for which it is given, from 3*d*. up to 10*s*. A receipt, though evidence of payment, is not absolute proof, and the evidence may be rebutted by showing that it has been given under mistake, or obtained by fraud. (Impey's *Stamp Act*; stat. 55 Geo. III., c. 184; 3 & 4 Will. IV., c. 23.)

RECEIVER. A Receiver is a person appointed by the Court of Chancery to receive the rents and profits of land, or the produce of other property, which is in dispute in a cause in that court. He is an officer or agent of the court, and as such under its general control.

A receiver is never appointed unless a suit is pending concerning the property in question; and he can only be appointed upon motion in court, after notice has been given to the proper parties. The motion is generally made after answer; under special circumstances it may be made before answer, but the motion must be supported by sufficient affidavits. The cases in which a receiver is appointed are those in which there is great danger of property being wasted or lost, owing to the want of a proper person to look after it. The following are some instances in which a receiver will be appointed: when an infant is entitled to real estate, especially if it be of considerable magnitude; in suits between partners in trade for the purpose of winding up the concern, when a partner is grossly misconducting himself, disposing of the partnership property, or excluding his copartners from the management of the partnership affairs; when the representation to a person deceased is in dispute in the ecclesiastical courts, and no person has been appointed executor; but if probate has been granted, and there is a suit in the ecclesiastical courts for recalling probate, a receiver will not be granted on that ground only (Watkins v. Brent, 1 M. and C., 97); when there is danger of the assets of a testator being lost or wasted through the misconduct of an executor. A manager of West India estates has power to set and let them, and to expend money in repairs; but a receiver has not such power, except as hereafter mentioned.

Certain persons are disqualified from being receivers, such as a solicitor in the cause, the next friend of the infant plaintiff, a peer of the realm, and a receiver general of a county. The order which is made on motion for the appointment of a receiver, refers it to the master to appoint a proper person, and the master's appointment is conclusive, unless it can be shown to the court that he has appointed an improper person. The receiver must find sufficient sureties, according to the value of the property of which he is appointed receiver; and on the sureties being approved by the master, they and the receiver enter into recognizances before him, and he makes his report of the appointment, which is filed in the report-office.

It is the duty of the receiver, when his appointment is completed, to inform the tenants of the estate in question of his appointment, by the production of the order and the master's report appointing him receiver, that they may pay the rents to him. In every order which directs the appointment of a receiver of landed property, there must be inserted a direction that such receiver shall manage as well as set and let, with the approbation of the master, who is to receive any proposal for the management or letting of the estate from the parties interested, but he must make his report thereon to the court for confirmation in the usual way.

A receiver may distrain for rent, but he must distrain in the name of the person who has the legal estate. If there is a receiver of the rents of an estate under an appointment of the court, an action of ejectment cannot be brought against the tenants in possession, nor against him, if he is actually in possession, without the leave of the court (Angel v. Smith, 9 Ve., 335); nor can a receiver defend an ejectment, and charge the expense of the defence in his account, without leave of the court.

A receiver is paid by a per centage on the sum which he receives, usually a shilling in the pound; and sometimes, in the case of large estates, by a fixed salary. But the court, on making an order for a receiver, may refuse to allow a salary; and it often happens that one of the parties in the suit, with the consent of the others, undertakes the office of receiver without a salary. He must annually pass his accounts of receipts and payments before the master, who prepares a report of passing the account, which is filed in the report-office, and does not require confirmation. It is directed in the order or decree for the appointment of a receiver, that the receiver shall from time to time pay the balances which shall be reported due from him into the Bank, with the privity of the accountant-general, to the credit of the cause. A receiver who does not pass his accounts and pay in the balances may be deprived of his salary. (15 Ve., 273.) If he make default in payment of the balances, the recognizances may be put in suit, or an order of the court may be obtained, upon motion and notice to the receiver, that he pay in the balance by a certain day, or stand committed. A receiver of rents and profits has to pass yearly or half yearly accounts, as the rents and profits are received, and he is chargeable with interest at 5 per cent. on balances in his hands which he neglects to pay at the times fixed for that purpose. A receiver of personal estate retaining balances in his hands will lose his salary but in respect of interest he is only to be charged as an executor would be, who had received personal estate. (Potts v. Leighton, 5 Ve., 273.)

When the receiver has passed his final account before the master, procured the master's report thereof, and filed it, and paid the balance into the Bank, or to the person entitled to receive the money, to whom the order directs him to pay it, he may apply by petition to the court for the vacating of the recognizances and his own discharge, and an order will be made accordingly, upon all the facts being proved to the court, which are the foundation of the receiver's right to his discharge.

A receiver is not liable to make good unavoidable losses.

RECEIVER. [Report.]

RECESS. This word is so familiar as to need no explanation, and it can hardly be classed among architectural terms; but that the subject of recesses should hitherto hardly have been treated of at all by professional writers, is somewhat remarkable, because there is nothing which contributes more to effect, or affords greater scope for design and fresh combinations in interior architecture. We shall here briefly notice the several circumstances which belong to recesses, and which tend to modify their character. Besides those of *plan*, *elevation*, and *section*, there are others, one of which is that of *relative size*, as compared with the rest of the plan. Ordinary shallow recesses—which kind might be distinguished by the name of *blank recesses*, since they are little more than breaks in the wall, and do not at all affect the general plan of a room—hardly belong to the subject, since they admit of scarcely any variety. By recesses we here mean those which come under the denomination of exhedræ, tribunes, alcoves, and afford considerable additional space. In plan these may be either curved or rectilinear, that is, semicircular (like the tribune of a Roman basilica) or segmental; or else polygonal, or rectangular, in which latter case the plan may be either a parallelogram, or so deep as to be a perfect square. Neither are these the only varieties of plan, for in each instance the recess may be either simple or *expanded*, that is, wider within than the breadth of the opening towards the room. If the plan be curved, it is usual to make the elevation in the form of an arch, either plain or decorated, in which latter case, it is sometimes the practice either to continue the archivolt without any impost, or to make it rest upon the entablature or capitals of pilasters. Elevations of this class however are only *astylar*: it is when columns come to be introduced into them, that alcoves admit of so many combinations and so much variety of design. The usual mode indeed is merely to separate the recessed part of the plan from the rest by a single line of columns, or rather, by only two columns, forming a *distyle in antis*,—that number being seldom exceeded; but it is by introducing columns behind and within—by extending the recess either laterally or in its background—by admitting light into it from above—that novel and scenic effects may here be produced almost without number. As regards utility and convenience, it is unnecessary to point out the advantage attending a deep alcove for the side-board in a dining-room, communicating immediately with a staircase for the attendants,—of which kind the tribune in the dining-room at Holkham furnishes one of the earliest and best examples; but alcoves and recesses add also to the commodiousness of other apartments—libraries, drawing-rooms, &c., affording nooks for study, or conversation apart, similarly to the spacious bays and recesses of that kind in Gothic mansions.

RECIPROCAL, a mathematical term mostly applied to the fraction made by inverting another fraction; thus $\frac{7}{4}$ is the reciprocal of $\frac{4}{7}$, and $\frac{1}{7}$ of 7 or $\frac{7}{1}$. The term arises from the common meaning of the adjective reciprocal, and would be properly applied in every case in which A has to B the same sort of relation that B has to A. Custom however confines the absolute use of the term to that above mentioned. A reciprocal property is one which each of two things has with reference to the other; thus if A and B be what are called conjugate diameters of a conic section, the tangent at either extremity of A is parallel to B, and that at either extremity of B is parallel to A. Hence these lines are reciprocally connected with each other, and are therefore called conjugate; for the word conjugate, which denotes joined, generally means joined by a reciprocal property.

RECITATIVE (*Recitativo*, It.), language delivered in musical tones, that is, in the sounds of the musical scale, It differs from air in having no fixed time or measure, the lengths of the notes depending on the singer, who regulates them according to his own notion of the emphasis and expression required; and it is not governed by any principal or predominant key, though its final cadence or close must be in some cognate key of the air which follows, or, at least, in no very remote key. Recitative is of two kinds—*Unaccompanied* and *Accompanied*. The first is when a few occasional chords are struck by the piano-forte, or by a violoncello, to give the singer the pitch, and intimate to him the harmony. The second is when all, or a considerable portion, of the instruments in the orchestra accompany the singer, either in sustained chords or in florid passages, as the composer may deem expedient, in order to give the true expression or colouring to the passion or sentiment to be expressed. Perhaps the Italian definition of Recitative, *musica parlante*—speaking music—is the best, as it certainly is the most concise, that can be offered.

There can be no doubt that the language of the antient drama, both Greek and Roman, was delivered in a kind of recitative. [MUSIC; OPERA.]

RECKONING AT SEA is the process of computing the several elements which relate to the determination of the ship's place at any time. The term may include the operations which are performed in finding the latitude and longitude of the ship, the variation of the needle, &c., from celestial observations; and the part which is independent of these is called the *dead-reckoning*. It is this last only which we purpose here to explain.

When a ship crosses the seas towards the place of its destination, its path, on account of the various winds, currents, &c. by which it is impelled, is always indirect, and generally consists of numerous zig-zags, whose portions are lines of a few miles in length. The length of each of these lines, and the angle which it makes with the terrestrial meridian passing through one of its extremities (all necessary corrections having been made) are the data obtained by the *log-line* and *compass;* and the earth being supposed to be a sphere, those lines might be considered as arcs of great circles. Hence the rules of spherical trigonometry might be employed to find the length of an arc joining the two extremities of the series of indirect lines, and the angle which it makes with the meridian passing through either of those extremities; and, from these, the geographical position of the ship. But, because this process is considered laborious, others possessing greater facilities are, according to circumstances, employed, and these will be described after it has been shown what are the corrections which the observed elements require before they can be used in the computations.

The reckoning may be said to commence when the ship is on the point of quitting a harbour or road; and the first circumstances to be recorded are the observed bearing and the estimated distance of some remarkable object on the coast whose geographical position is known, together with the bearing of the ship's line of motion at the time, and her velocity on that line.

Let it be here observed that the said object on the coast is called the point of *departure*, and that the angle which the line of a ship's motion at any time makes with the meridian passing through the actual position of the ship is called her *course*. Now, while the angle indicated by the compass remains the same, the ship's path, except when it coincides with the meridian, or with a line tending due east and west, is a portion of that which is called the *loxodromic curve* [RHUMB-LINE]; yet, to the extent of a few miles, it is the custom to consider it as a right line, and, therefore, as making a constant angle with the meridian passing through one of its extremities. The deviation of the magnetic from the true meridian (the declination or variation of the needle) differing in different places, the amount of that variation (ascertained by celestial observations as often as possible) must be added to or subtracted from the angles observed with the compass, in order to have the bearing, or course, from the true meridian. But while a ship is sailing with the wind in a direction oblique to the line of her keel, she is compelled, by the force of the wind and the resistance of the water against her side, to move in the direction of a line which makes some angle with her keel on the side opposite to that from which the wind is blowing; this angle is called the *lee-way*, and as it differs for different ships, it must always be determined by trial in some one of the ways proposed in treatises on navigation. The estimated amount of the lee-way is a second correction, which must be applied to the course observed with the compass, in order to obtain the correct angle with the meridian.

The velocity of the ship is ascertained by means of the log-line [LOG-LINE], which at once indicates the number of geographical miles (equatorial minutes) she has passed over in an hour; and consequently, supposing her motion to be uniform, the space through which the ship has sailed on a particular course in a given number of hours is known. This is technically called the *distance*.

Again, when a ship is sailing either in a current of the ocean, or in a tide near a shore, her velocity and the direction of her motion will be affected by those of the current or tide. First, if the ship is impelled by the wind in the same direction as the current is moving, it is evident that the velocity given by the log will be only the difference between the ship's real velocity and that of the current, and consequently the latter must be added to the velocity given by the log in order to have the true velocity. On the other hand, if the ship is impelled by the wind in a direction contrary to that of the current, the velocity of the latter must be subtracted from that given by the log, in order to obtain the true velocity of the ship. Again, if the direction of the current is oblique to the line of the ship's motion according to the compass, the true path and velocity of the ship will, by the *composition of motions*, be the diagonal of a parallelogram formed on lines representing the observed directions and velocities of the ship and current; consequently, since this rule is the same as that by which is found a path of the ship which shall be equivalent in length and direction to any two successive paths whose lengths and directions are given, it is evident that among the registered courses and velocities of a ship it will be only necessary to insert the observed direction and velocity of the current, as if the ship had actually moved in that direction, and with that velocity during the time that she continued to sail in the current. The like remark may be made respecting the deviation of a ship from the course on which she appears by the compass to have sailed, in consequence of a swell of the sea, by which she may be driven in some other direction. This direction must be observed, and the velocity estimated according to the judgment of the seaman.

Now, in order to show how all the corrections may be applied to the observed elements, let it be supposed that at the noon of some day a remarkable object A on the shore was observed by the compass to bear W. by N., and that its estimated distance from the ship was 20 miles. At the same moment let the ship begin to sail on a course which is S.W. by the compass; and let the velocity by the log be 3 knots, or 3 miles per hour. Also let the following table express the several memoranda in the order in which they may be supposed to have been made in the course of one day; that is, according to the practice of seamen, between the noon of one day and the noon of the next.

The bearing of the ship from the point of departure being corrected for the variation of the needle becomes N. 77° 15′ E.; the distance is 20 miles.

The first course corrected in like manner becomes S. 21°

Day of Month.	Hour.	Knots.	Wind.	Course.	Lee-Way.	Remarks.
	Noon.	3	W.N.W.	S.W.	0.	The point A of departure bore
	2 P.M.	4½		(or S. 45° W.)		W. by N., distant 20 miles; its
	8	5½				lat. ——, and long. ——.
	10	6	W. by N.	S.E. by S.	¼ E., or	A swell setting towards E.N.E.
	12	4½		(or S. 33° 45′ E.)	2° 49′ E.	from 2 P.M. to 8 P.M.: velocity
	6 A.M.	5½				6 miles per hour.
	8	6	W.	S.S.W.	1 E., or	A current setting towards S.S.E.
	10	6½		(or S. 22° 30′ W.)	11° 15′ E.	from 10 P.M. to 10 A.M.: velocity 3
						miles per hour. Variation N. 24° W.

W.; and the distance run between noon and 10 P.M. is 43·5 miles.

The third course corrected for lee-way and variation becomes S. 60° 34′ E.; and the distance run between 10 P.M. and 8 A.M. is 50·5 miles.

The fourth course corrected in like manner becomes S. 12° 45′ E.; and the distance run between 8 A.M. and noon is 25 miles.

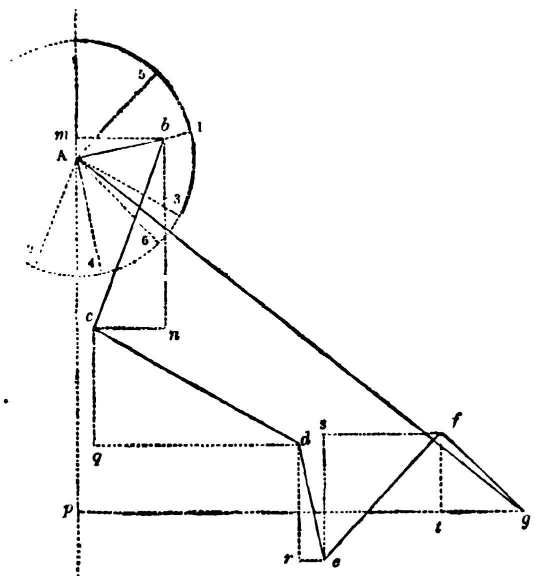
The direction of the swell corrected for the variation of the needle becomes N. 43° 30′ E.; and the distance is 36 miles. Lastly, the direction of the current corrected also for the variation becomes S. 46° 30′ E.; and the distance is 24 miles.

These corrected courses and distances are then inserted in order, as in the first and second columns of the following table:—

Courses.	Distances	N.	S.	E.	W.
N. 78° 15′ E.	20	4·07 (=A*m*)	. . .	19·58 (=*bm*)	. . .
S. 21° W.	43·5	. . .	40·7 (=*bn*)	. .	15·59 (=*cn*)
S. 60° 34′ E.	50·5	. . .	24·82 (=*cq*)	43·98 (=*dq*)	. . .
S. 12° 45′ E.	25	. . .	24·38 (=*dr*)	5·52 (=*re*)	. . .
N. 43° 30′ E.	36	26·11 (=*se*)	. . .	24·78 (=*sf*)	. . .
S. 46° 30′ E.	24	. . .	16·52 (=*ft*)	17·41 (=*gt*)	. . .

Now, if the navigation is comprehended within about ten degrees on each side of the equator, such a zone of the earth may be supposed to be projected on the interior surface of a circumscribing cylinder, and then developed on a plane; in which state the meridians and the parallels of latitude become right lines parallel to themselves respectively, and the length of a degree of longitude on every parallel equal to that of a degree on the equator or on the meridians. This is called the *plane chart*, and the projection of a ship's path on it is called *plane sailing*.

Let the several directions in which the ship has moved, and the distances passed over in each direction, be represented in the subjoined diagram, the construction of which, agreeably to the nature of the plane chart, is as follows:—



Draw the lines A 1, A 2, A 3, &c., making with Ap, the meridian of the point of departure, angles equal to the several courses as they occur successively in the preceding table (col 1), and draw the lines *bc*, *cd*, &c. parallel to A2, A3, &c. respectively; the distances A*b*, *bc*, *cd*, &c. being laid down according to the successive numbers in col. 2 by a scale of equal parts representing geographical miles (or equatorial minutes). At the end of the day the ship is arrived at the point *g*; therefore if A and *g* be joined, and *gp* be drawn perpendicularly to A*p*, the angle *p*A*g* is the resulting course, A*g* the resulting distance, A*p* the difference of latitude between A and *g*, and *pg* is what is called the *departure*, which, in plane sailing, is identical with the difference of longitude between the same points A and *g*.

By drawing lines perpendicular and parallel to A*p*, as in the above diagram, there will be formed the several right-angled plane triangles A*bm*, *bcn*, &c., in each of which there are given the hypotenuse and the angles; and consequently by the rules of plane trigonometry the several sides A*m*, *bm*, *cn*, *bn*, &c. may be computed. Now, let these computed values be placed in the third and succeeding columns of the above table in the following order:—those which are parallel to A*p* in the column N. or S., according as the lines which represent them lie towards the north or towards the south of that extremity which is first, in order of sailing, on the corresponding hypotenuse; and those which are perpendicular to A*p* in the column E. or W., according as the lines which represent them lie towards the east or west of that same extremity. Then the sum of the numbers in the column N. being subtracted from the sum of those in S. will be found to leave 76·24, and this will be the value of A*p* in geographical miles (or equatorial minutes); consequently 1° 16′ 14″ will express the extent in latitude to which, on the whole, the ship has sailed southwards during the day. Again the number in W. being subtracted from the sum of those in E will leave 95·68 (=1° 35′ 41″), and this will be the value of *pg*, or the extent in longitude which, on the whole, the ship has sailed eastward during the day. Thus the position of A being known, we have that of *g*. In the right-angled plane triangle A*pg*, having A*p* and *pg* in miles, as above, we may compute A*g* and the angle *p*A*g*, that is, the resulting distance and course. The former will be found to be =122·35 miles, and the latter S. 51° 27′ E. The series of zig-zag lines which a ship may describe is called a *traverse;* the preceding table is called a *traverse table*, and the whole operation of finding the resulting course and distance is called *traverse sailing*.

In practice, both the construction and calculation above indicated are superseded by the use of the table of *difference of latitude* and *departure*, which is given in treatises on navigation. The numbers in the table are nothing more than the computed values of the sides of right-angled triangles; the hypotenuse, or the distance, and the adjacent angle, or the course, being given. Thus by referring to such a table, the courses and distances being used as arguments, the numbers in the columns N. S. E. W. above, might have been found sufficiently near the truth. And, conversely, seeking in the table the difference of latitude (=76) and the departure (=96), the corresponding distance (=122) would be seen in its proper column, and the angle or course (=51°) at the bottom of the page.

The logarithmic or Gunter's scale [SCALE] was formerly for the sake of expedition, much used in the resolution both of plane and spherical triangles for the purposes of navigation. If, for example, it were required by that instrument to find the values of *cq* and *qd* in the triangle *cqd*, the following proportions

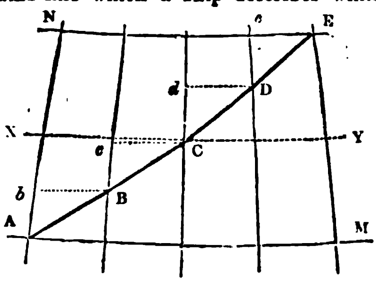
Rad. : sin. *qcd* (60° 34′) : : *cd* (50·5) : *qd* (=44)
Rad. : sin. *cdq* (29° 26′) : : *cd* : *cq* (=25)

might be worked by taking in the compasses the distance from 90° to 60° 34′ on the line of sines, and applying that distance on the line of numbers from 50·5 towards zero; the other foot of the compasses would fall on 44, which is the value of *qd;* again by taking the distance from 90° to 29° 26′ on the line of sines, and applying it on the line of numbers, from 50·5, as before, the other foot of the compasses would fall on 25, which is the value of *cq*. But it is evident that when the angle is small, or nearly a right angle, the instrument must be very inaccurate.

Should a ship, on any part of the earth's surface, sail for a short time in a direction either due east or due west, so that during that time it might be considered, without sensible error, as sailing on the circumference of a parallel of latitude, the determination of its place is obtained by a different process. Thus, the earth being supposed to be a sphere, the length, in miles, of any arc of the equator between the meridian circles passing through its extremities is to the length, in miles, of the arc between the same meridians on any given parallel of latitude as radius is to the cosine of the latitude of the parallel. Therefore, when the number of geographical miles passed over on any parallel of latitude is known by the log (all due corrections being supposed to be made), the difference of longitude corresponding to that distance may be found at once by the above proportion. Evidently also, if any three whatever of the terms are given, the fourth can be found; and thus every variation of the case may be resolved. This is called *parallel sailing*.

But the tables of difference of latitude and departure may be rendered available for finding the required term if we consider the latitude of the parallel on which the ship is sailing to represent what is called the *course* in those tables; the distance in miles on the parallel as the *difference of latitude*, and the difference of longitude in geographical miles as the *distance* in the tables; and then, by inspection as before, the required term may be found.

The third method of operating, which is called *middle latitude sailing*, has been defined under LONGITUDE AND LATITUDE, METHODS OF FINDING, and we have here only to point out its application. Let AE be a portion of the rhumb-line which a ship describes while her mo-



tion continues to coincide with the direction of one point of the compass, that is to say, while it makes a constant angle with the meridians of her successive places. Let this curve be divided into any parts, AB, BC, &c. of small extent, so that each part may, without sensible error, be considered as a straight line; and imagine both meridians and parallels of latitude to be drawn through A, B, C, &c. Then the several triangles BAb, CBc, &c. being considered as plane triangles, if the constant angle BAb, CBc, &c. be represented by A, we shall have—

AB cos. A = Ab , BC cos. A = Bc , &c.; also
AB sin. A = Bb , BC sin. A = Cc , &c.; whence, by addition,—

(AB + BC + &c.) cos. A = Ab + Bc + &c., and
(AB + BC + &c.) sin. A = Bb + Cc + &c.

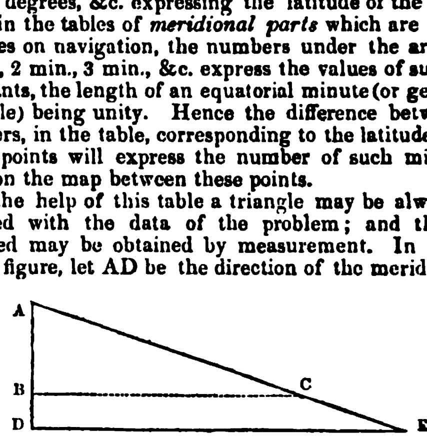
It is evident therefore that the sum of all the distances multiplied by the cosine of the course will be equal to EM, the difference between the latitudes of A and E as in plane sailing; but the sum of all the distances multiplied by the sine of the course (that is, the sum of all the departures, Bb, Cc, &c.) will be less than AM and greater than NE. Therefore, as an approximation to the truth, we may consider the sum of all these departures as the length, in miles, of the arc XY (between AN and ME) of a parallel of latitude equally distant from AM and NE; that is, of a parallel whose latitude is an arithmetical mean between the latitudes of A and E. Consequently, as in the theorem for parallel sailing, the difference between the longitudes of A and E will be obtained from the proportion

Cos. *mid. lat.* (= lat. of XY) : Rad. :: (AB + BC + &c.) sin. A : diff. of long.;

and, instead of working the proportion, the tables of difference of latitude and departure may be used as before.

If we imagine the earth's surface to be developed on a plane so that the meridians and parallels of latitude may be respectively parallel to themselves as in the plane chart; and if the lengths of infinitely small portions of the circumference of the equator have to the lengths of corresponding portions of a meridian, in any latitude, the ratio that the radius bears to the secant of that latitude [MERCATOR'S PROJECTION; RHUMB-LINE], there may be formed a species of chart which will afford a general and at the same time a sufficiently easy method of determining the elements relating to a ship's place. This method is called *Mercator's sailing*. In the chart just alluded to, the length of a degree, minute, &c. of longitude, on any parallel of latitude, is constant, being the same as the length on the equator, on account of the parallelism of the meridians; but, in any latitude, the length of a small meridional arc (which, without sensible error, may be of one minute) varying with the secant of the latitude of the arc, the distance, on the map, of any parallel of latitude from the equator will be equal to the sum of the secants of all the minutes in the degrees, &c. expressing the latitude of the parallel. Now, in the tables of *meridional parts* which are given in treatises on navigation, the numbers under the arguments 1 min., 2 min., 3 min., &c. express the values of such sums of secants, the length of an equatorial minute (or geographical mile) being unity. Hence the difference between the numbers, in the table, corresponding to the latitudes of two given points will express the number of such minutes or miles on the map between these points.

By the help of this table a triangle may be always constructed with the data of the problem; and the terms required may be obtained by measurement. In the subjoined figure, let AD be the direction of the meridian pass-



ing through the ship at A, and BAC be her course: then if AC be made equal to the distance in miles by a scale of equal parts, and BC be drawn perpendicular to AD, AB and BC measured on the same scale will be the differences of latitude and departure as in plane sailing. Now, if AD be made, by the same scale, equal to the difference between the meridional parts which, in the table, correspond to the latitudes of the point A and C, and DE be drawn parallel to BC, DE on the same scale will express, in miles or minutes, the true difference between the longitudes of A and C.

What has been said may serve as an example of the manner of constructing the triangle, when the course, the distance, and the latitudes of the two extremities of the distance-line are given, and it is required to find the difference between the longitudes of those extremities. Again, let the ship's course and distance from any point A, and also the latitude of that point, be given, to find the differences both of longitude and latitude. The formation of the triangle ABC is the same as that just mentioned, and AB being measured on the scale of equal parts is the true difference of latitude (in miles or minutes); this being added to or subtracted from the latitude of A, gives the latitude of C. Then, with these latitudes, find from the table the difference between the meridional parts, and proceed as before to find the difference of longitude. If the latitudes of the ship in two places were given and also the distance between those places, and it were required to find the course and the difference of longitude:—on the meridian line passing through one of the places A, make AB equal to the difference of latitude in miles by the scale of equal parts, and make AD by the same scale equal to the difference between the meridional parts, in the table, corresponding to the latitudes; then draw the indefinite perpendiculars BC and DE, and from A as a centre with a radius equal to the given distance describe an arc intersecting BC in C. Join A and C, and produce the line to E; then ∠BAC will be the course, and DE, measured as before, the difference of longitude.

It is easy to perceive that the table of differences of latitude and departures may be used in Mercator's Sailing in the same way as it would be employed in Plane Sailing, if the meridional difference of the latitudes, from the table of meridional parts, be made to hold the place of the simple difference of latitude. Thus, in the second of the above examples, with the given course and distance, find by inspection in the first-mentioned table the difference of latitude; then, having got by addition or subtraction the latitude of the place at which the ship is arrived, find in the table of meridional parts the numbers corresponding to those latitudes, and take their difference. Lastly with this difference, as a simple difference of latitude, and with the course, find the departure by inspection in the first table; this departure is the required difference of longitude.

When a ship is in a high latitude, it is necessary to determine the difference of longitude, either by middle latitude or by Mercator's sailing, for every particular course on which the ship may have sailed.

The daily differences of latitude and longitude being thus obtained, the seaman knows, within the degree of accuracy of which his data admit, the latitude and longitude of the ship on any day; but it is easy to perceive that the uncertainties respecting the estimates of the distances run, the variations of the needle, the effects produced by currents, &c., must, in time, render the results of the reckoning very erroneous; and therefore it is of the utmost importance to correct them frequently by celestial observations. The determination of the latitude by meridional or other altitudes is easy; and that of the longitude by lunar distances or by chronometers should be made as often as possible. Every geographical position thus determined with precision serves, by comparison with the results of the dead-reckoning, to lead to a knowledge of the causes of the errors which exist in the latter, and becomes a point of departure for the next succeeding portion of the voyage.

RECOGNIZANCE is an obligation of record, entered into before some court of record, or magistrate duly authorised, by which the party entering into it (the cognizor), whose signature is not necessary, acknowledges (recognizes) that he owes a sum of money to the king, or to some private individual, who is called the cognizee. This sum is termed the amount of the recognizance. The acknowledgment is generally followed by an undertaking on the part of the cognizor to do some act, such as to keep the peace, to pay a sum of money, to attend to give evidence, &c. On the performance of this act, the cognizor is discharged from his recognizance. On his default, the recognizance is forfeited, and he becomes indebted absolutely to the amount of the recognizance. A debt on recognizance takes precedence of other debts, and binds the lands of the cognizor from the time of its enrolment. If the recognizance is made to a private individual in the nature of a statute staple, &c., he may on its forfeiture, by virtue of process directed to the sheriff, obtain delivery of the lands and goods of the cognizor till the debt is satisfied, or proceed against the cognizor in an action of debt, or by scire facias. If the recognizance is made to the king, it was formerly, in all cases of forfeiture, estreated into the exchequer, and afterwards recovered by process from that court to the use of the treasury. But now, in the cases of forfeited recognizances taken before the court of quarter sessions, or justices of the peace, provision is made by stats. 3 Geo. IV., c. 46, and 4 Geo. IV., c. 37, for their enrolment among the sessions records, and their immediate recovery by the sheriff. A list of the amounts, &c. is yearly returned by the clerks of the peace and town-clerks for their districts respectively, to the lords of the treasury. A power of appeal by the cognizor against the forfeiture is given to the sessions, and the sheriff is not to levy on the cognizor till the appeal has been decided. Where a recognizance has been estreated into the exchequer, that court may discharge or compound it according to the justice of the case. (Com. *Dig.*, 'Recognizance;' Dalton; 2 Bl. *Com.*; Burn's *Justice*.)

RECONNOISSANCE is an examination of a tract of country or of the sea-coast; the latter previously to a disembarkation of troops, and the former preparatory to the march of an army in order either to meet that of the enemy or to take up quarters for the season.

The *military reconnoissance* of a country is a duty appertaining to the officers on the staff of the quartermaster-general; and if the enemy is in the neighbourhood, it is performed under the protection of an armed force. It is considered as one of the most essential operations connected with the tactics of the field, and serves as the basis of every movement or combination which it may be proposed to make.

A general knowledge of a country which is or may become the seat of war, that is to say, a knowledge of the positions of its fortified places, the directions of its mountains, rivers, and great roads, may be obtained from maps or from geographical descriptions; but that which is necessary for the immediate purposes of a campaign can only be acquired by an actual survey of the ground in detail, and by inquiries made on the spot respecting the means which the country may afford for supplying the wants of the army.

The Maréchal Puységur (1690) appears to have been the first in modern warfare who regularly performed this duty by examining personally the tract through which the army was to march or in which it was to encamp, and of the riding beforehand on the best routes and positions. He observes (*Art de la Guerre*) that before his time it had been customary to trust, for a knowledge of these points, to the reports of the country people, or of officers who might accidentally have been on the ground. He adds that disasters frequently occurred by the lines of march being improperly chosen, and that sometimes, after fatiguing marches, and after all the labour of encamping had been undergone, the troops had been compelled to abandon the positions on account of their unfitness. Since that time armies being more numerous and more widely disseminated, consequently requiring more vigilance in the communication of one part with another, and a greater extent of country for their support, the reconnoissances have been made on a greater scale, and in the military establishments of every nation officers are now particularly instructed in all the details of that branch of service.

Those who are charged with this duty should be habituated to the performance of topographical surveys: in the first place by the most accurate methods and with the best instruments; and, secondly, by such methods as admit of being practised rapidly on foot or on horseback. In these cases a compass held in the hand must be used for observing the angles, and the distances must be obtained by pacing, or be merely estimated by the eye. A facility in representing on the plan the inequalities of the ground is also highly necessary.

In making the reconnoissances previously to the march of an army, the whole of the ground between the actual position of the latter and that which is intended to be occupied should be surveyed if the enemy is near and there is danger of his attacking the columns by surprise; otherwise it may be sufficient to survey the ground within a few hundred paces on each side of the roads by which the columns are to march. A complete plan of the tract of country in which the reconnoissance is made may therefore be required; or it may suffice to represent on paper the line or lines of march. In either case, the officer may be provided with a general map, or an itinerary of the intended route as an outline for his guidance; and his survey, when completed, should be accompanied by a report or memoir, stating in detail what cannot be conveniently represented on the plan. In this report should be expressed, with all necessary references to the plan of the ground, the distances, by the different routes, between the two positions, and the places where troops may halt for repose or to form in order of battle; distinguishing particularly the plains where cavalry may act, and the heights on which artillery may be placed. The nature of the roads should be described, with indications denoting that they are passable for artillery, for cavalry, or merely for infantry; and if defective, estimates should be made of the materials and time requisite for repairing them. It is particularly necessary to state whether the ascents and descents are gentle or abrupt; and, when the road is on the side of a hill, whether it is sufficiently level to allow artillery or carriages to pass safely: it should also be noticed whether or not, at places where roads run through towns, they are reduced to narrow and winding streets. The breadths and velocities of rivers, streams, and canals which cross the lines of march should be ascertained, and a statement made whether the beds are rocky, gravelly, or muddy; also whether the banks are high or low. Mention should also be made of the means which exist for passing them; of the places where they are fordable, where there are ferries or bridges, or where boats may be procured; descriptions should also be given of the bridges or boats, and the manner of working the latter. The situations and extent of marshes should also be shown, and it should be stated whether they are passable or can be made so. In contemplating rivers and marshes as means of retarding an advance of the enemy, it should be ascertained and reported whether, by being dry in summer or frozen in winter, they may not at times cease to be obstacles: it should also be stated how, on a retreat, the roads may be blocked up, the fords rendered impassable, or the bridges destroyed.

Should a sufficient number of roads for the different columns not exist, the officer is to ascertain whether or not others may be made by cutting through hedges, walls, or woods, by forming causeways over marshes, or by constructing or repairing bridges over rivers or streams; and also whether the country affords the materials necessary for those purposes. The rates at which it is possible for troops to march in the several roads, defiles, &c. must be estimated according to the breadth of the latter or the degree of their practicability; for on a right estimate of such rate, together with the known length of the road, depend the number of battalions and the class of troops which ought to be appointed to follow each particular route, when it is required that the different columns should arrive at the same time in some given position. The plan should show the situations of farms, mills, houses, &c. which may be capable of being defended or of affording quarters for the troops; and on it should be indicated, by some scale of numbers or otherwise, the relative heights of the ground, that it may be ascertained what positions can be occupied with advantage for offensive or defensive operations. The representation of a simple line of march should also indicate the places where roads diverge from or cross the route, with the distances of the nearest towns or villages from thence; and any particular survey of the ground for an encampment should extend to at least a mile every way beyond the supposed chain of outposts. [MILITARY POSITIONS; PIQUET.] The report must state what are the resources of the country in corn, cattle, and forage; and the number of carriages, horses, and other draught animals that it may furnish for the conveyance of artillery and stores. If the line of march is in the direction of a navigable river which may be available for the last-mentioned purpose, it will be necessary to ascertain its breadth and rapidity, and also the obstructions which may be met with from shallows, weirs, &c. Marshal Suchet caused his artillery to be conveyed by the Ebro from Mequinenza to Xerta, in 1810, preparatory to forming the siege of Tortosa.

An open country presents the greatest facilities for reconnoitring, since the positions of its towns or villages, and the directions of its roads and rivers, can then be easily distinguished and represented on paper. A tract covered with wood is not only surveyed with difficulty, but it imposes on the officer, in addition, the necessity of ascertaining all the directions in which it is capable of being penetrated by the enemy, and in what manner the passes may be blocked up or defended. Open plains intermingled with wood, fields surrounded by hedges, ground intersected by streams of water, ravines, and hollow ways, demand great exactness in the survey, since such tracts afford the most important advantages, both in the higher and in the secondary operations of warfare, to the army which is best acquainted with their details. They allow troops to pass unseen from one point to another when a surprise is attempted or a rapid retreat is to be made; they also afford cover from whence the enemy may be annoyed with little loss. In mountainous districts it is important to ascertain the forms and directions of the chains of heights, with their acclivities on both sides; and, if the line of march is between them, the collateral ravines should be examined to a considerable distance: the commencements and directions of the ravines should also be shown, and all the defiles by which the valleys communicate with each other. Through these defiles troops detached from the army are enabled to fall suddenly on the enemy during his march, to separate his columns, and intercept his supplies or cut off his retreat; and, on the other hand, since the enemy may attempt the like measures, it becomes necessary that the officer employed to reconnoitre should ascertain by what means the passes may be barricaded either to impede the enemy or enable the troops to defend themselves.

In reconnoitring a country, when it is intended to act on the defensive, it should be well known by what roads the enemy can penetrate, and where are the best situations for forming intrenched camps or establishing posts in order to be enabled to keep the field and cover the magazines. Again, if it be intended to carry the war into an enemy's country, it is necessary to discover the position occupied by his army; to find the tract of country most proper for the march, and the spots where the localities permit encampments to be formed with due support on the flanks and security in the rear. If it be intended to besiege a fortress or to attack the enemy's position, the reconnoissance may be made quite up to the glacis of the place, or to the works which protect the position. In the former case it is necessary to ascertain the nature of the fortifications, and the fitness of the ground about them for the operations of the siege; and in the latter, to find out the strength and dispositions of the enemy's troops. An armed force is generally required on these occasions, as, in order to approach near enough for the purpose, it may be necessary to drive in some of the outposts. During the war which ended in 1814, the English and French out-sentries appear to have entertained a mutual understanding not to molest each other, and to retire to their supports before they commenced firing when either army was about to make a movement. Colonel Napier relates that Lord Wellington, being once desirous of reconnoitring the enemy's position at Bayonne, ordered his escort to fire upon some of the enemy who occupied the top of a hill which he wished to ascend; but one of the men going up to the French soldiers and tapping his musket in a particular way, the latter, who understood the signal, quietly withdrew.

In a *maritime reconnnnoissane* the circumstances which it is of most importance to ascertain are: whether the coast is rocky or bordered by downs, and what is the state of the bays or roads with respect to shelter from the prevailing winds; the seasons in which winds blow off and on the shore, and whether the anchorage is secure or otherwise, the nature of the tides, the hours of high and low water, and the depth at either of those times. Precise information should also be obtained of the places at which troops might land, and where there exist rising grounds on which artillery may be disposed to protect them. Rivers should be ascended to a considerable distance if possible, in order to ascertain their depths and the nature of the vessels employed on them by the people of the country. On the other hand, if it were required to examine the coast preparatory to putting it in a state of defence, it would be necessary to find out what points of land are convenient for the situations of forts or batteries by which the enemy may be prevented from landing, and where beacons may be established for the purpose of giving timely alarm. If there are islands on the coast, it would be proper to include them in the survey, since they might be fortified and made to serve as advanced works; and all places should be indicated which are capable of being converted into military posts to prevent the enemy from penetrating into the interior of the country.

RECORD, a memorial in rolls of parchment of the proceedings and acts of a court of law, upon whose proceedings error will lie. An act of a party which is put on record cannot be varied even in the same term, but a judicial act of the court may be altered during the same term. If a record is lost, the court may order a new entry to be made at any time. In order to prove a record the existence of which has not been denied on the pleadings, an examined copy is sufficient. But if the existence is denied on the pleadings, it can only be proved upon inspection by the court of the record itself; and that is conclusive not only as to the existence of the record, but as to all matters stated in it. For the record of a court of competent jurisdiction is legally considered as the indisputable proof of all those proceedings having taken place which the record sets forth; and no averment to the contrary in pleading can be made. A record found in the proper office is legally assumed to have been always in the same plight in which it is found. The effect of a reversal of a judgment in error is to annul the previous record from the commencement. (*Co. Litt.*, 117 b., 260 a.; Com. *Dig.*, tit. 'Record.') It seems doubtful whether in all cases a record must necessarily be on parchment. (Reg. v. Yeovely, 8 A. and E., 806.) As to what constitutes a Court of Record, see COURTS, and RECORDER.

RECORDE, ROBERT, an eminent mathematician of the sixteenth century, was the first native of Great Britain who introduced the study of analytical science into this country. There is no memorial of the exact time of his birth, though it must have been somewhere about the year 1500. We know that he was a native of Tenby in Pembrokeshire, that he entered himself a student at Oxford about the year 1525, where he publicly taught rhetoric, mathematics, music, and anatomy, and that he was elected a fellow of All-Souls College in 1531. Making physic his profession, he repaired to Cambridge, and in 1545 he received the degree of M.D. from that university, and, says Wood, was highly esteemed by all who knew him for his great knowledge in several arts and sciences. He afterwards returned to Oxford, where, as he had done previously to his visit to Cambridge, he publicly taught arithmetic and other branches of the mathematics with great applause. According to Fuller, he was of the Protestant religion. He afterwards repaired to London, at which place he resided in 1547, and in that year published a medical work entitled 'The Urinal of Physic,' which passed through several edi tion. He was also chosen physician to Queen Mary and Edward VI., to both of whom he dedicates some of his works. With the knowledge of this latter fact, it is scarcely possible to account for the circumstances in which he was at the time of his decease, a prisoner in the King's Bench. He died in the year 1558, probably soon after the date of his will (June 28), in which he styles himself 'Robert Recorde, doctor of physicke, though sicke in body yet whole in mynde.' This document is preserved in the Prerogative Office, and furnishes some facts. To Arthur Hilton, under-marshal of the King's Bench, his wife, and the other officers and prisoners, he gave small sums amounting to 6*l.* 15*s.* 8*d.*; to his servant John, 6*l.*; to his mother, and his father-in-law, her husband, 20*l.*; to Richarde Recorde, his brother, and Robert Recorde, his nephew, his goods and chattels, out of which his debts and the expenses of his funeral were to be discharged. This last item leads us to think that debt was not, as commonly stated, the real reason for his imprisonment; although, indeed, the amount of property enumerated does not constitute a large sum even for those days. In a codicil to his will, made on the 28th of June, 1558, he gives directions that his law books should be sold to Nicholas Adams, a fellow prisoner, for 4*l.*

The works of Recorde are all written in dialogue between master and scholar, in the rude English of the time. They are enumerated by the author himself at the end of his work called 'The Castle of Knowledge,' and there is reason to think that two of his works mentioned in that place are irrecoverably lost, at least no trace of either of them has yet been discovered in print or manuscript. One of them appears to have been entitled 'The Gate of Knowledge,' and the other 'The Treasure of Knowledge.'—Recorde's most popular work appeared as early as 1540, under the title of 'The Grounde of Artes, teachinge the worke and practise of Arithmeticke, both in whole numbers and fractions, after a more easier and exacter sort than any lyke hathe hitherto beene set forth.' We have taken this title from the edition of 1573, the earliest we have yet met with. 'The Grounde of Artes' was dedicated to Edward VI., and continued to be repeatedly reprinted until the end of the seventeenth century, the latest edition we have seen being that edited by Edward Hatton in the year 1699. This work contains numeration, addition, subtraction, multiplication, division, reduction, progression, the golden rule, a treatise on reckoning by counters on a principle much resembling that of the Chinese abacus, a system of representing numbers by the hand like the alphabet of the deaf and dumb, a repetition of all the rules for fractions, with the rules of alligation, fellowship, and false position. On the last rule he remarks that he was in the habit of astonishing his friends by proposing difficult questions, and working the true result by taking the chance answers of 'suche children or ydeotes as happened to be in the place.' 'The Pathway to Knowledge,' a brief compendium of geometry, translated and abridged from the Elements of Euclid, was published at London in 1551.

'The Castle of Knowledge' was published in 1556, dedicated in English to Queen Mary, and in Latin to Cardinal Pole. This work is written in the form of a dialogue between master and scholar on astronomy, and from the preface we gather that Recorde had not altogether abandoned astrology. It begins with an account of the Ptolemaic system, and afterwards proceeds, in an apparently concealed passage, to unfold the elements of the Copernican system of the universe. This passage has already been given in the *Companion to the British Almanac for* 1837, and more latterly in the *Philosophical Magazine*; we do not therefore consider it necessary to repeat it in this place. Recorde appears to have been one of the earliest persons in this country who adopted the Copernican system, if not the earliest person who introduced it among us. All that is cited from Euclid and Proclus is in Greek and Latin, usually both, and Lascaris's edition of the latter author is referred to; but the edition of Euclid is not mentioned.

In the 'Whetstone of Witte,' which was published in 1557, Recorde has amassed together the researches of foreign writers on the subject of algebra, then in its infancy, and has also incorporated several improvements of his own. In algebra we recognise Recorde as the inventor of the sign of equality, and of the method of extracting the square root of multinomial algebraic quantities. In perception of general results connected with the fundamental notation of algebra, he shows himself superior to others, and even, we may say, to Vieta, although of course immeasurably below the latter in the invention of means of expression. All his writings considered together, Recorde was an extraordinary genius; and it must be remembered he was a lawyer, a physician, and a botanist, as well as the first mathematician of his day.

(Principally taken from a pamphlet by J. O. Halliwell, Esq., on *the Connexion of Wales with the early Science of England*, 8vo., 1840, and from an article in the *Companion to the British Almanac for* 1837, by Prof. De Morgan.)

RECORDER (*Recordator*), a judicial officer, described by Cowell as 'he whom the mayor or other magistrate of any city or town corporate having jurisdiction, or a court of record, within their precincts by the king's grant, doth associate unto him for his better direction in matters of justice and proceedings according to law.' The Norman term, *recordeur*, appears to have originally been applied to every person who was present at a judicial proceeding, and to whose remembrance, or record, of what had taken place the law gave credit in respect of his personal or official weight and dignity. Of this we perceive a trace in the ordinary writ of Accedas ad Curiam, by which the sheriff is commanded to go to some inferior court (which, not being the king's court, is not a court of record), taking with him four knights, and there to record the plaint, which is in that court; the remembrance of the four knightly recordeurs of what they saw existing in the inferior court, in obedience to the king's writ, being treated as equivalent to their actual presence at the proceeding to be recorded. So if the proceedings are in the sheriff's court, he is ordered by the writ of Recordari facias loquelam to cause the plaint to be recorded by four knights. And by a record of the eighth year of King John, we find that a judgment of battle in the court of the archbishop of Canterbury being vouched in the king's courts, four knights were sent to inspect the proceedings, who returned 'quod recordati sunt.' (*Placitorum Abbreviatio*, 54.) The practice of certifying and *recording* the customs of London *by the mouth of the recorder*, which is antecedent to the charters granting or recognising the practice, appears to be referrible to the same source. Where criminal or civil jurisdiction was exercised by citizens or burgesses, it would add to the importance of the court if its proceedings took place in the presence of an officer to whose *record* the superior courts would give credit, either in respect of his personal rank, as a peer or knight, or on account of his connection with those courts, as a serjeant or barrister-at-law. [SERJEANT.]

Since 1835 the duties of recorders in the cities and boroughs enumerated in the schedules of the Municipal Corporations Act (5 and 6 Will. IV., c. 76) have been regulated by the provisions of that and of subsequent statutes.

The jurisdiction of the recorder in places of minor importance than those mentioned in the schedules, being taken away, will not require to be noticed. Nor do these acts affect the city of London.

I. The recorder of London is a judge having criminal and civil jurisdiction. He is also the adviser and the advocate of the corporation. In respect of the duties performed by the recorder in the assemblies of the corporation, in the courts of mayor and aldermen, of common council, and of common hall, his office may be said to be ministerial. He is by charter a justice of the peace within the city of London, and a justice of oyer and terminer, and a justice of the peace, in the borough of Southwark.

The first charter of Edward IV. to the city of London grants that the customs of the city be certified and *recorded* by word of mouth, and that the mayor and aldermen of the city and their successors do declare by the recorder whether the thing under dispute be a custom or not.

The business of the mayor's court, in which the recorder ordinarily presides alone, comprehends a court of equity. In the mayor's court the recorder tries civil causes, both according to the ordinary course of common law and the peculiar customs of the city. The amount for which such actions may be brought is unlimited. In London, causes depending in the superior courts at Westminster for sums under 20*l.*, writs of trial are occasionally ordered to be executed by a judge of a court of record in London under statute 3 and 4 Will. IV., c. 42, s. 17. Such trials sometimes take place before the recorder, and sometimes before the judges of the sheriffs' court.

Cases of felony and misdemeanour, and appeals against poor-rates and convictions, arising in the borough of Southwark, are tried before the recorder at the quarter-sessions held for that borough. All the duties of a justice of the peace, including those of chairman, devolve upon the recorder at the quarter and other sessions held at Guildhall for the city of London. At the eight sessions which are held in the year at Justice-hall in the Old Bailey for the metropolitan district, the recorder acts as one of the judges under her majesty's commission of oyer and terminer, and general gaol delivery. At the conclusion of each session he prepares a report of every felon capitally convicted within the metropolitan district, for the information and consideration of the queen in council, and he issues his warrant for the reprieve or the execution of the criminals whose cases have been reported.

The fixed annual salary of the recorder is 1500*l.* The Common Council have added 1000*l.* annually to the salary of the present recorder, and to that of his immediate two predecessors. Besides this, the recorder has fees on all cases and briefs which come to him from the corporation. He is also allowed to continue his private practice.

The recorder is elected by the court of aldermen, most commonly at a special court held for the purpose. Any alderman may put any freeman of the city in nomination as a candidate for the office, but an actual contest seldom takes place. The recorder elect is admitted and sworn in before the court of aldermen. The appointment is during good behaviour, that is, in contemplation of law, for life. The recorder has always been a serjeant-at-law or a barrister. The office has been held by men of considerable eminence: of eleven persons who filled the situation during the last century, one became lord chancellor; another, master of the rolls; another, chief justice of the Common Pleas; and two, barons of the Exchequer. Latterly however, as the duties of the office have occupied a large portion of the recorder's time, counsel in extensive practice have not been desirous of the situation.

By an order made by the court of aldermen in the reign of Philip and Mary, the recorder, common-serjeant, and under-sheriff were directed to be chosen 'from old and learned officers of the city or out of the number of the six learned counsellors,' that number comprehending, in addition to the ordinary city counsel, the attorney and solicitor-general, who were always retained for the city. Three persons by whom the recordership of London has been held during the present century, have previously filled the office of common-serjeant. [SERJEANT.] But no similar instance occurred during the eighteenth century.

The recorder of London deriving his authority from charters, and not being appointed by commission (except temporarily as included with other judges in the commission of oyer and terminer, &c. at the Old Bailey), he is not, like the judges of the superior courts, liable to dismissal by the crown upon an address by both Houses of Parliament. But all recorders may be removed for incapacity or misconduct by a proceeding at common law.

Deputy recorders have in some instances, but not very lately, been appointed by the court of aldermen on the nomination of the recorder. (*Report on Municipal Corporations.*)

II. In cities and boroughs within the Municipal Corporations Act, the recorder (who must be a barrister of not less than five years' standing) is a judicial officer appointed under the sign manual by the crown during good behaviour, having criminal and civil jurisdiction within the city or borough, with precedence next to the mayor.

Criminal jurisdiction is given to recorders by the Municipal Corporations Act, explained by subsequent statute. The 105th section of that Act provides that the recorder shall hold once in every quarter of a year, or at such other and more frequent times as he shall in his discretion think fit, or as the crown shall think fit to direct, a court of quarter-session of the peace, at which the recorder shall sit as the sole judge, and such court shall be a court of record, and shall have cognizance of all crimes, offences, and matters whatever cognizable by any court of quarter-session of the peace for counties in England, provided nevertheless that no recorder shall have power to make or levy any rate in the nature of a county-rate, or to grant licence to keep an alehouse or victualling-house, to sell exciseable liquors, or to exercise any of the powers by that act specially vested in the town council.

The jurisdiction of the county sessions extends, under 34 Edw. III., c. 1, to the trying and determining of all felonies and misdemeanours. The commission under which county justices are appointed however directs that if any case of difficulty arise, they shall not proceed to judgment but in the presence of one of the justices of the courts of King's Bench or Common Pleas, or of one of the justices of assize; and courts of quarter-session in counties have latterly treated every case in which judgment of death would be pronounced upon conviction, as a case of difficulty, and have left such cases to be tried at the assizes; and though no such direction is contained in the grant of the office of recorder or in the Municipal Corporations Act, it has been the invariable practice of recorders appointed under the Act to refrain from the exercise of jurisdiction in such cases. [SESSIONS.]

In the session of 1839 a bill was introduced into the House of Commons for confining the jurisdiction of courts of quarter-session, both for counties and for boroughs, to certain minor offences,—but the bill did not pass.

The civil jurisdiction given to recorders by 5 and 6 Wm. IV., c. 76, § 118, is to try actions of assumpsit, covenant, or debt, whether by specialty or by simple contract, and all actions of trespass or trover for taking goods or chattels, provided the sum or damages sought to be recovered do not exceed 20*l.*, and all actions of ejectment between landlord and tenant wherein the annual rent of the premises does not exceed 20*l.*, and upon which no fine has been reserved, with an exception of actions in which title to land, or to any tithe, toll, market, fair, or other franchise is in question in courts, which before the passing of the Act had not authority to try actions in which such titles were in question. This enactment does not take away the more extended civil jurisdiction which previously existed in particular cities and boroughs by prescription or by charter.

The practice, or mode of proceeding, and also the course of pleading, in courts of civil jurisdiction in cities and boroughs is governed by rules made by the recorder and allowed by three judges of the superior courts.

RECORDER, a musical instrument formerly in use; 'a flageolet or small English flute, the mouthpiece of which, at the upper extremity of the instrument, resembled the beak of a bird; hence the larger flutes so formed were called *flutes à bec*. The recorder was soft in tone, and an octave higher than the flute. Milton speaks (*Par. Lost*, i. 550) of

"The Dorian mood
Of flutes and *soft recorders*."

It would appear, from Bacon's *Sylva Sylvarum*, cent. iii., 221, that this instrument was larger in the lower than in the upper part; and a wood-cut of the flageolet in Mersenne's *Harmonie Universelle* leads to the same conclusion. On the etymology of the word much ingenuity has been bestowed, but without any satisfactory result.' (*Note in Pict. Shaksp.*, 'Hamlet,' Act iii., Sc. 2.)

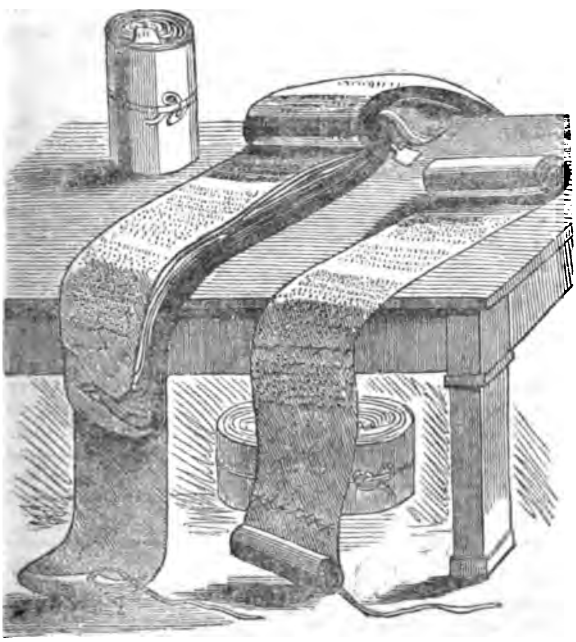
RECORDS, PUBLIC. Authentic memorials of all kinds, as well public as private, may be considered in one sense as records. Thus the Metopes of the Parthenon are indisputable records of Grecian art; the journal stamp on a letter is a record that it has passed through the post-office; a merchant's ledger is a record of his business; and every lord of a manor may keep written records of his courts, as the chancery, the exchequer, and other courts do of their proceedings. But our present purpose is to give some general account of the public records, properly so called, understanding by the term the contents of our public record offices.

Records, in the legal sense of the term, are contemporaneous statements of the proceedings in those higher courts of law which are distinguished as courts of record, written upon rolls of parchment. (Britton, c. 27.) Matters enrolled amongst the proceedings of a court, but not connected with those proceedings, as deeds enrolled, &c., are not records, though they are sometimes in a loose sense said to be 'things recorded.' (2 Sell., *Abe.*, 421.) In a popular sense the term is applied to all public documents preserved in a recognised repository; and as such documents cannot conveniently be removed, or may be wanted in several places at the same time, the courts of law receive in evidence examined copies of the contents of public documents so preserved, as well as of real records. [COURTS; RECORD; RECORDER.]

The course we propose to take, is to treat that as a record which is thus received in the courts of justice. The act [illegible] instance, which abolished Henry VIII.'s court of augmentation (of the revenues obtained from the suppression of the religious houses), declared that its records, rolls, books, papers, and documents, should thenceforth be held to be records of the court of exchequer; and accordingly we have seen many a document, originally a mere private memorandum, elevated to the dignity of a public record, on the sole ground of its official custody, and received in evidence as a record of the Augmentation-office. On the other hand, numbers of documents which were originally compiled as public records, having strayed from their legal repository to the British Museum, have thereby lost their character of authenticity. (*Proceedings of the Privy Council*, vol. v., p. 4, edited by Sir Harris Nicolas.)

'Our stores of public records,' says Bishop Nicolson, and, we believe, with perfect accuracy, 'are justly reckoned to excel in age, beauty, correctness, and authority, whatever the choicest archives abroad can boast of the like sort.' (Preface to the *English Historical Library*.) Yet rich as our own country is beyond all others of modern Europe in the possession of antient written memorials of all branches of its government, constitutional, judicial, parliamentary, and fiscal, memorials authenticated by all the solemn sanctions of authority, telling truly though incidentally the history of our progress as a people, and handed down in unbroken series through the period of nearly seven centuries—the subject of its public records now appears, we believe, for the first time in a work like the present. The amount of public care given to this subject during the last forty years, is shown by the appointment of successive commissions and parliamentary committees of inquiry, by a cost in one shape or another amounting to little less than a million of pounds sterling, and by the passing of an act of parliament designed to effect a thorough change in the system of keeping and using the public records.

By far the greater part of records are kept as rolls written on skins of parchment and vellum, averaging from nine to fourteen inches wide,* and about three feet in length. Two modes of fastening the skins or membranes were employed,



that of attaching all the tops of the membranes together bookwise, as is employed in the exchequer and courts of common law, whilst that of sewing each membrane consecutively, like the rolls of the Jews, was adopted in the chancery and wardrobe.

The solution of the reasons for employing two different modes has been thought difficult by writers on the subject. It appears to have been simply a matter of convenience in both cases. The difference in the circumstances under which these rolls were formed, accounts, we think, satisfactorily for the variation of make. In the first case, each inrolment was often begun at one time and completed at another. Space for the completion of the entry must have been left at hazard. Besides several scribes were certainly engaged in inrolling the proceedings of the courts, and the roll was liable to be unbound, and to receive additional membranes after it had once been made up. In the other case, the business of the chancery being simply registration, the scribe could register the documents before him, with certainty that nothing in future would at all affect their length, and he was enabled to fill every membrane, and perfect the roll as he proceeded.

In the *volumina*, or *scapi*, of the antients, the writing, was carried in equal columns, as in the pages of a book, along the length of the skin, whilst the inrolment in both sorts of our rolls was written across the width of the membrane. Both these kinds of rolls are still used. The rolls of the common law, after the time of Henry VIII., contain so many skins that they cease to be rolls, but become simply oblong books, and, unlike the early rolls of the same series, are exceedingly ill adapted for preservation and inconvenient for use. There are many of these miscalled rolls of the reign of Charles II., which in shape, size, and weight resemble the largest of Cheshire cheeses, often requiring two men to lift them from the rack. Membranes may be fastened together after the chancery fashion in any numbers, and yet remain a legitimate roll, though imposing much bodily labour in the consultation. The land-tax commissioners' Act of 1 Geo. IV. extends, it is said, 900 feet when unrolled, and employs a man three hours to unroll the volume. Other records have the shape of books. Doomsday Book, called both 'Rotulus' and 'Liber,' the oldest and most precious of our records, counting eight centuries as its age, and still in the finest order, is a book; and as occasions presented themselves for adopting this shape without infringing on antient precedent, the far more accessible shape which we now call a 'book' seems to have been employed. A considerable part of the records of the courts of surveyor-general and augmentations, in the reign of Hen. VIII., of wards and liveries, and requests, are made up as books. Other documents, those relating to Fines, the 'Pedes Finium or Finales Concordiæ,' the writs of 'Dedimus Potestatem,' and acknowledgments and certificates, writs of the several courts and returns, writs of summons and returns to parliament, inquisitiones post mortem, &c. &c., by tens and hundreds of thousands are filed, that is, each document is pierced through with a string or gut, and thus fastened together in a bundle.

The material on which the record is written is generally parchment, which, until the reign of Elizabeth, is extremely clear and well prepared. From that period until the present, the parchment gradually deteriorates, and the worst specimens are furnished in the reigns of George IV. and William IV. The earliest record written on paper, known to the writer, is of the time of Edward II. It is one of a series entitled 'Papirus magistri Johannis Guicardi contra-rotulatoris Magnæ Costumæ in Castro Burdegaliæ, anno domini M°. ccc°. viii°.' These records are in the office of the queen's remembrancer of the exchequer.

Tallies were records of wood. [Tally.]

The handwriting of the courts, commonly called court-hand, which had reached its perfection about the reign of our second Edward, differs materially from that employed in chartularies and monastic writings. As printing extended, it relaxed into all the opposites of uniformity, clearness, legibility, and beauty which it once possessed. The ink too lost its antient indelibility; and, like the parchment, both handwriting and ink are the lowest in character in the latest times: with equal care, venerable Doomsday will outlive its degenerate descendants.

All the great series of our records, except those of parliament, are written in Latin, the spelling of which is much abbreviated, and in contractions, there can be little doubt, derived from Latin manuscripts. The reader who desires to be further informed on the subject may consult the collection which Mr. Hardy has inserted in the preface to his 'Close Rolls of King John,' and Mr. Hunter, in his preface to the 'Fines of Richard I. and John.' During the Commonwealth, English was substituted; but soon after the Restoration, Latin was restored, and the records of the courts continued to be kept in Latin until abolished by act of parliament in the reign of George II. In certain branches of the Exchequer, Latin continued in use until the abolition of the offices in very recent times. Many of our

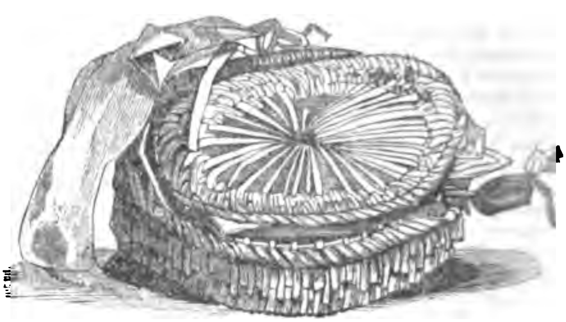
* The rolls of the Great Wardrobe exceed eighteen inches in width.

statutes from Edward I. to Henry V., and the principal part of the rolls of parliament, are written in Norman French. Petitions to parliament continued to be presented in Norman French until the reign of Richard II., whose renunciation of the crown is said to have been read before the estates of the realm at Westminster first in Latin and then in English. After this period we find English, which had doubtless always remained in use among the lower classes, often used in transactions between the people and government—a sure sign that the distinctions of Norman origin were nearly absorbed among the people at large.

Sir Francis Palgrave's edition of the 'Calendars and Inventories of the Treasury of the Exchequer,' some of which were compiled as early as the fourteenth century, are extremely interesting in exhibiting the antient modes in which records were preserved. Whilst reading them we may imagine ourselves groping in the dark and damp vaults of the 'treasury' of the Exchequer, among the coffers, chests, boxes, and hampers filled with records, and the walls around us covered with small bags and pouches. No uniform system of arrangement seems to have been employed, but a different expedient was used for the preservation of nearly every separate document. Great numbers, judging from the quantity found in arranging the miscellaneous records of the king's remembrancer of the Exchequer, were kept in pouches or bags of leather, canvas, cordovan, and buckram, a mode which is still used in this department of the Exchequer. These pouches, which fasten like modern reticules, are described by Agarde, who was keeper of the treasury of the Exchequer, 'as hanging against the walls.' The following drawing represents a leathern pouch containing the tallies and the account of the bailiff of the manor of Gravesend in the 37 and 38 of Edward III.

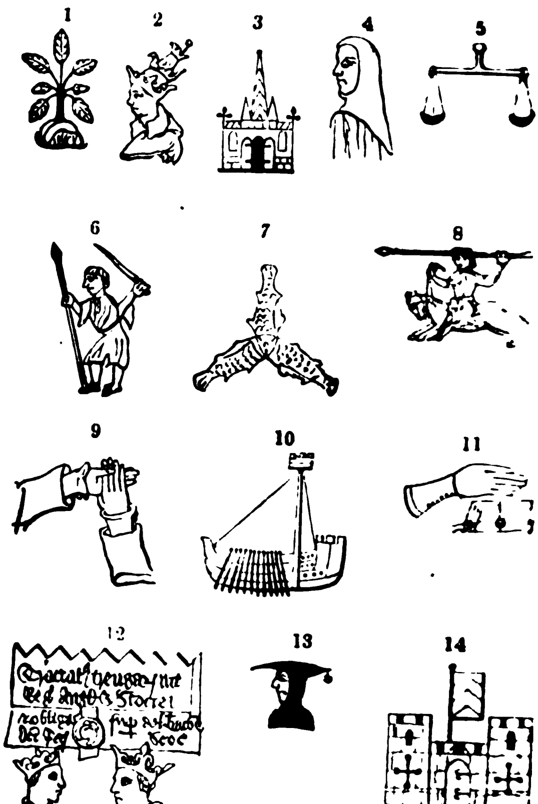
When they have escaped damp, they have preserved their parchment contents for centuries in all their pristine freshness and cleanliness. Chests, coffers, coffins, and 'forcers' bound with iron and painted of different colours, cases or

'scrinia,'* 'skippets,' or small turned boxes, and hanapers, or 'hampers of twyggys,' were also used.



These two last illustrations are about one-third of the size of the originals, which remain in the 'treasury' of the Exchequer.

Inscriptions on labels, letters, and 'signs' furnished the means of reference. We owe the following specimens of these 'signs' to the kindness of Sir Francis Palgrave, who has obliged us with the loan of the blocks, cut for his Calendars of the Exchequer before mentioned. These signs in most cases bear some analogy to the subject of the documents which they are intended to mark.



The rolls of the justices of the forest were marked by the sapling oak (No. 1). Papal bulls, by the triple crown. Four canvas pouches holding rolls and tallies of certain payments made for the church of Westminster were marked by the church (3). The head in a cowl (4) marked an indenture respecting the jewels found in the house of the Fratres Minores in Salop. The scales (5), the assay of the mint in Dublin. The Briton having one foot shod and the other bare, with the lance and sword (6), marked the wooden 'coffin' holding the acquittance of receipts from Llewellyn, Prince of Wales. Three herrings (7), the 'forcer' of leather bound with iron, containing documents relating to Yarmouth, &c. The lancer (8), documents relating to Aragon. The united hands (9), the marriage between Henry, Prince of Wales, and Philippa, daughter of Henry IV. The ga…

* The Romans kept their records in 'Scrinia,' respectively distinguished as 'Scrinia Viatoria; Scrinia Stataria; Scrinia Palatii; Scrinia Sacra; Scrinia Augustæ.'

(10), the remembrance of merchants of the three galleys of Venice. The hand and bank (11): fealty to kings John and Henry. The charter or cyrograph (12), treaties and truces between England and Scotland. The hooded monk (13), advowsons of Irish churches. And the castle with a banner of the Clare arms (13), records relating to the possessions of the earl of Gloucester in Wales.

Our ancestors before the Norman conquest pursued no system of public registration, though there are numerous charters of the Anglo-Saxon kings and deeds between private individuals still existing, and historical events are found chronicled in monastic chartularies.

The Anglo-Saxons, whose judicial proceedings were conducted orally, had no records except the 'land-bocs' or charters. The transactions of the folk-moots were not registered or *recorded*, and in the administration of justice no reference was made to written precedents. In such a *state of society*, though the actual possession of land constituted one of the best titles to real property, still the 'land-boc' furnished evidence of it also. And so important were these 'land-bocs' considered, that when the monks of Ely purchased seven hydes and a half of land, they gave three hydes besides thirty 'aurei' to recover the *charter* or 'cyrograph' of the title. Duplicates and triplicates of these 'land-bocs' were made, and one 'part' was delivered into the custody of the Hordere, or chamberlain, to be preserved in the 'horde,' or royal treasury.

When a written record is made of any act, it is clear that it is made not for the exclusive benefit of one party only. In the Doomsday-book of the Norman conqueror, we see evidence that his power was far from absolute. The financial registrations (Rotuli Pipæ) of Henry I., in whose reign the earliest example is found—the records of the judicial proceedings of the 'Curia Regis,' which begin with Richard I.—and the special *acts* of the monarch himself enrolled on the 'close,' 'patent,' and 'charter' rolls commencing in the reign of John—are all so many irresistible proofs how gradually larger interests were trenching on the will of the king, who formerly recognised no other power than his own in the government of the kingdom. The judicial records of the King's Bench and Common Pleas, and the parliamentary records beginning with Edward I., are further *evidence* of the increasing influence of the nobles and commonalty of the realm.

The king was legally considered as possessing the sovereign power. His peace was broken when the subject fell by the hand of the murderer; his parliament was to be summoned; his honour to be vindicated; and his army to be levied. It was the king's exchequer, the king's wardrobe, the king's court, and essentially the king's chancery; for the chancellor's functions were originally those of a private secretary, combining duties both spiritual and temporal. Holding the keepership of the king's conscience, the chancellor was necessarily of the clerical body, and the chief of the king's chapel. The great seal was in his custody, and the scope of his secretarial duties embraced all those of modern times performed by our secretaries of state for the home and foreign departments; and of all the business transacted a systematic and orderly registration was preserved in the several enrolments called 'patent,' 'close,' 'charter,' &c. All records of these several departments formed part of the king's treasure; and, like the treasure of the ancient Persians five hundred years before the Christian era, when Darius caused a search for the decree of Cyrus to be 'made in the house of the rolls, where the treasures were laid up in Babylon' (*Ezra*, 6, 1), were deposited in the king's 'treasuries.'* The mutual interest of all parties naturally made the preservation of the records an object of general solicitude; to the king, as they furnished indisputable precedents for his calls of military service and taxation; to the nobles in protecting them in their feudal rights and various privileges; and to the commons most of all, in limiting the powers both of king and nobles, sheltering them from capricious extortion, and securing to them a certain amount of consistency in the administration of justice.

The chamberlain of the exchequer was called 'une grand office, car il gardera le treasour del roy, & les records.' In Henry III.'s reign there were treasuries in the Tower of London and the New Temple. *From* the latter place, in the 20th of Edward I., out of a chest secured by nine keys, certain records of the Chancery were taken by the king's orders. (*Rot. Claus.*, 20 Edward I., m 13 d.) The Tower had certainly become a permanent treasury for records in the 33rd of Edward I., when a transfer to it was directed to be made of all the papal privileges touching the crown or kingdom, from the treasury of the exchequer at Westminster. (*Rot. Claus.*, 33 Edward I., m. 3.) Another 'treasury' is described by certain 'memoranda,' made 19 Edward III., as within the cloister of Westminster Abbey, near the Chapter-House (thesauraria Regis infra Claustrum Abbatiæ Westmonasterii juxta Capitulum). This 'treasury' still remains. A single pillar supports the vaulted chamber, which is yet to be seen, with its double oak doors grated and barred with iron and locked with three keys, and its drawers and 'tills' labelled by Arthur Agarde, who was custos of the records it contained. In his 'Compendium of the Records in the Treasury,' compiled 1610, he says that 'the recordes of the kinge's majesties threasury at Westminster, under the custodie of the lord threasurer and the two chamberlaines, were lay'd up for their better preservacion in fower severall threasuries under three severall kayes, kept by three sundry officers, distinct the one kay from another, and uppon each dore three lockes. The first in the Court of Receipt; the seacond in the Newe Pallace at Westminster, over the Little Gatehouse there; the third in the late dissolved abbey of Westminster, in the Old Chapter-House; the fourth in the cloister of the sayd abbey.'

The contents of several 'treasuries' at various periods seem to have been consolidated in the Chapter House of Westminster Abbey, which was fitted up in its present state for the reception of records by Sir Christopher Wren. The only existing depositories of records besides the Chapter-House which preserve the appellation of 'treasury,' are the rooms in the Rolls-House, being the 'treasury' of the King's Bench Records, and a portion of the Carlton Riding-House as the 'treasury' of the Common Pleas Records.

The demolition of the old 'treasuries' adjoining Westminster Hall scattered their contents in all quarters of the metropolis. Thus the records of the king's remembrancer, of the Exchequer, and the Common Pleas, migrated from Westminster Hall to the late Mews at Charing Cross; and thence, to make room for the National Gallery, to Carlton Riding-School. The records of the late lord-treasurer's remembrancer and Pipe-Office are entombed two stories deep in the vaults of Somerset House. Those of the King's Bench for a time rested opposite St. Margaret's Church, but were shifted to the Rolls-House in Chancery Lane to make room for the present Rolls Court at Westminster.

Thus from time to time have repositories, as well undignified with the antient title of 'king's treasury' as deficient in that careful superintendence which originally accompanied the title, arisen in all parts of London; and in 1837 a committee of the House of Commons reported that it had seen the Public Records, the most precious part of the king's 'treasure,' deposited at the Tower over a gunpowder-magazine, and contiguous to a steam-engine in daily operation; at the Rolls, in a chapel where divine service is performed; in vaults two stories underground at Somerset House; in dark and humid cellars at Westminster Hall; in the stables of the late Carlton Ride; in the Chapter-House of Westminster Abbey; in offices surrounded by and subject to all the accidents of private dwellings, as the Augmentation Office and First Fruits.' At the present time, besides the offices for modern records attached to each court, we may enumerate the following repositories, with their different localities, as containing the public records:—

The Tower, in Thames Street.
Chapter-House, Westminster Abbey.
Rolls Chapel, Chancery Lane.
Rolls House, Chancery Lane.
Duchy of Lancaster, Lancaster Place, Strand.
Duchy of Cornwall, Somerset House.
Common Pleas, Carlton Ride and Whitehall Yard.
Queen's Remembrancer's Records, in Carlton Ride and tower of Westminster Hall.
Augmentation-Office, Palace Yard, Westminster.
Pipe-Office, Somerset House.
Lord-Treasurer's Remembrancer, Somerset House.
Land Revenue, Carlton Ride.
Pell-Office, 1, Whitehall Yard.

* [illegible]

Exchequer of Pleas, 3, Whitehall Yard.
First-Fruits Office, Temple.

It would seem that as early as the commencement of the fourteenth century the officers charged with the custody of the records were found to be either insufficient or neglectful of the performance of their duties. Since the time of Edward II. scarcely a reign has passed without a special temporary agency being appointed to restore the public records to good order. The necessity probably arose from the functions of the officer charged with the care of the records being altogether changed, as in the instance of the master of the Rolls, who was the *bonâ fide* 'gardein des roules' in early times.

In the 14th Ed. II., the barons of the Exchequer were directed to employ competent clerks to methodise the records, which were 'not then so properly arranged for the king's and the public weal as they ought to be.' Again in the 19th year of Ed. II., certain commissioners were appointed for a similar purpose. In Edward III.'s reign, at least three like commissions were issued (*Rot. Claus.*, Annis 34 and 36; and *Rot. Parl.*, Anno 46). Statutes for the protection of records from falsification, erasure, and embezzlement were passed 8 Rich. II., c. 4, and 11 Hen. IV., c. 3. Other measures were taken by Hen. VI., Hen. VII., and Hen. VIII. Inquiries into the state of the Parliamentary, the Chancery, and Exchequer Records were prosecuted in Queen Elizabeth's reign. James I. proposed 'an office of general Remembrance for all matters of record,' and a State Paper Office, which Charles II. established. Nor were the reigns of Anne and the two first Georges wanting in investigations into the subject. Committees of both Houses of Parliament from time to time visited the several repositories, and the fire of the Cottonian Library in 1731 produced a report which describes the condition of most of the public repositories at that period. But the fullest examination into the state of the public records which has been made in recent times was effected by a Committee of the House of Commons, in 1800, conducted by lord Colchester, then Mr. Abbot, and the report of that Committee presents by far the most perfect and comprehensive account which has yet appeared of our public records, to which a period of forty years has added very little. This Report originated a commission for carrying on the work which its authors had begun. The Record Commission was renewed six several times between the years 1800 and 1831, and altogether suspended at the accession of the present queen. All the several record commissions during thirty years recited, one after another, that 'the public records of the kingdom were in many offices unarranged, undescribed, and unascertained;' that they were exposed 'to erasure, alteration, and embezzlement,' and 'were lodged in buildings incommodious and insecure.' The commissioners were directed to cause the records to be 'methodized, regulated, and digested,' bound and secured; to cause 'calendars and indexes to be made and 'original papers' to be printed. The present state of the Record Offices affords abundant evidence, that the record commissioners interpreted their directions in an inverse order; expending the funds entrusted to them rather in printing records than in arranging or calendaring them. And it is an undoubted fact that notwithstanding these commissions, records were 'embezzled'—and are still lodged in most 'insecure' buildings. A very full investigation into the proceedings of the record commission was made by a Committee of the House of Commons in 1835, and the reader who is curious to know more than our space allows us to state, may consult its Report. Certainly during the last half-century there has been no niggard expenditure in one shape or another in respect of the public records. It is not very easy to ascertain its total amount or the precise appropriation of it; but the following may be received as an approximation to correctness:—

Parliamentary Papers show that grants were made on behalf of the Record Commission between 1800 and 1831, to the amount of	£362,400
Between 1831 and 1839 inclusive . . .	125,700
Salaries, &c. for the custody of Records .	120,000
Fees, estimated on an average of the years 1829, 1830, and 1831, at least . . .	120,000
Removals of Records, estimated at . .	30,000
	758,100
Irish Record Commission, estimated at .	120,000
	£878,100

Of the grants made to the record commission, by far the greater part was spent in printing and the expenses connected therewith. At the conclusion of this paper we have given a list of the works that they published, many of which are undoubtedly of great utility.

A very important step has recently been taken by the legislature to provide for the better custody and preservation and more convenient use of the public records. An act was passed (1 and 2 Vic., c. 49) calculated to remedy effectually what preceding efforts had in vain attempted, by constituting a special agency for the custody of the records; to the want of which and a sufficient responsibility, all the defects of the old system are attributable. By this act the Master of the Rolls is made the guardian of the public records, having powers to appoint a deputy, and, in conjunction with the treasury, to do all that may be necessary in the execution of this service. The act contemplates the consolidation of all the records, from their several unfit repositories, into one appropriate receptacle; their proper arrangement and repair; the preparation of calendars and indexes, which are more or less wanting to every class of records; and giving to the public more easy access to them. Lord Langdale, the present master of the rolls, to whose influence the change of system is greatly due, has already brought the above act into as full operation as circumstances have allowed. The old custodyship of most of the offices has been superseded, and the offices are constituted branches of one central depository, the Public Record Office, which, until a proper building is ready, is at the Rolls House in Chancery Lane. The Victoria Tower of the new Houses of Parliament has been named as a likely repository for the public records. The arrangement and repair as well as the making of inventories of records have been generally begun in most of the offices.

Preparations are also making for a uniform system of calendaring, a gigantic work which a century will hardly see completed. To select what is useful from the judgments of a single court, the Common Pleas for instance, at least 1[illegible]0 miles of parchment nine inches wide must be patiently read through; and yet, without the performance of this labour, these records can scarcely be consulted.

The principal changes which have been made for the better accommodation and access of the public may be seen in the following table:—

System before July, 1840.

Office.	Hours of Attendance.	Charges for Search.	Charges for Inspection of Record.	Charges for Copy of Record.	*Present System.*
Tower . .	10 till 3	10s.	6s. 8d.	1s. per folio	Attendance 10 till 4. Search in all Indexes, Calendars, &c. 1s. Inspection of a Record 1s. Copies 6d per folio. The public may make [illegible]
Rolls Chapel .	10 till 3	1s. a year ea. name	2s. 6d. ca. Roll	5s. 6d. a sheet	
Chapter House	10 till 1	8s. 4d.		1s. per folio	
Carlton Ride (Common Pleas)	10 till 4 In term-time only	3d a term 2s. 6d. in Index		6d. per folio	
3, Whitehall Yard Common Pleas	No attendance				
Exch. of Pleas	No attendance	3d. a term		6d. per folio	
King's Bench (Rolls House)	No attendance	2s. 6d in Index			

We can only find space to glance at the particular classes of the public records, noticing in the fewest words the more antient and valuable. No enumeration we could give would enable the reader to dispense with reference to the inventories, repositories, calendars, catalogues, and indexes which are printed, or those existing in manuscript in the various Record Offices. The best work of general reference is the 'Report of the Select Committee in 1800,' from which we have taken a brief analytical list of the subjects to which the public records relate. Though this list is not altogether what is to be desired, it is the best within moderate limits that we know of, and is sufficient to prove that there is perhaps no branch of the public administration of our country which is destitute of its authentic memorials. The subjoined list consists merely of the headings of a much fuller analysis of the public records, which shows also their age and place of deposit. It was compiled by Mr. Lüders, and is printed in the above Report.

ENGLAND.

I. *The King, Royal Family, and Household.*

1. The King. 2. The Queen. 3. The Prince of Wales. Household Privy Seals and Correspondence. Principality of Wales. Duchy of Cornwall. 4. Custos Regni, Lieutenant, Protector, Regent, Lord Justices. 5. Household. 6. The King's Chamber.

II. *The Royal Councils.*

1. Parliament. The House of Lords. The House of Commons. 2. Privy Council.

III. *The Royal Prerogative.*

1. In Ecclesiastical Affairs. Before and after the Reformation. Proceedings of the Commonwealth. 2. In Civil Affairs. General Administration of the Realm. Honours and Offices. Trade and Coin. 3. In Military and Naval Affairs. 4. In Foreign Affairs.

IV. *The Royal Revenues.*

1. Ordinary. Land Revenues. Casual Revenues. 2. Extraordinary.

V. *Courts of Justice.*

1. Of Abolished or Obsolete Jurisdiction. Curia Regis. Placita de Assisis. Placita Itineraria. Placita Forestæ. Placita Coronæ. •Placita Aulæ. Placita de Quo Warranto. Star Chamber Proceedings. Court of Requests. Court of Wards and Liveries. Court of Augmentations. Surveyor-General's Court. Court of Chivalry: viz. Constable and Marshal. 2. Of Occasional Jurisdiction. Special Commissions. Court of Judicature for determining Differences after the Fire of London. High Court of Justice. 3. Of Established Jurisdiction. Chancery. Its Ordinary and Extraordinary Jurisdiction. King's Bench. Pleas of the Crown and in Civil Suits. Common Pleas. Exchequer of Account—The Queen's Remembrancer's Office, The Lord Treasurer's Remembrancer's Office. Exchequer of Receipt—Tellers, Tally Court, Auditor or Tally Writer, Pell Office, Auditors of Imprest, Commissioners for auditing the Public Accounts. Exchequer of Pleas and of Error. Marshalsea and Palace Courts. Session of Oyer and Terminer and Gaol Delivery for London, and Gaol Delivery for Middlesex. Great Sessions of Wales. Duchy of Lancaster. Counties of Palatine. Stannary Courts. Cinque Ports. Commissioners of Sewers. Quarter-Sessions and Clerks of the Peace. Maritime Courts—Admiralty Instance Court, Admiralty Prize Court, Court of Appeal in Prize Causes. Ecclesiastical Jurisdiction—Episcopal, Archiepiscopal, Appellate Jurisdiction, Deans and Chapters. Courts for offences in India.

VI. *Universities and Colleges, Schools, &c.*

1. Universities and Colleges. 2. Royal Schools, Chaunteries, Hospitals, Colleges, Free Chapels, Fraternities, and Guilds.

VII. *Alienation of Private Property.*

SCOTLAND.

Title, Great Seal, Privy Seal, Signet, Chancery, Revenues, and Expenses. Acts of Civil Government. Ecclesiastical Government. 2. Parliament. 3. Privy Council. 4. General Registers. 5. Courts of Justice. Court of Session. Justiciary Court. Court of Exchequer. Admiralty Court. Commissary Courts. Court of Teind. Sheriff Court. 6. Universities.

IRELAND.

The principal Record Repositories in Dublin are the *Bermingham Tower*, which contains Plea Rolls, Pipe Rolls, Summonisters' Rolls, Sheriffs' Tot Rolls, &c.; the *Parliamentary Record Office;* the *Rolls Office;* the Statute Rolls from Hen. V. to the Union; Patent and Close Rolls from 1 Ed. I. to the present time; Inquisitions post Mortem; Fiants from 21 Hen. VIII. to the present time; Decree Rolls; Recognizance Rolls from 21 Hen. VIII; the *Chief Remembrancer's Office*, Memoranda Rolls from 6 Ed. I. to the present time; the *Auditor-General's Office*, Rolls of Public Accounts from Hen. VIII.; the Receiver-General, Vice-Treasurer's, Pell's, and Chamberlain's Books, the Debenture Exchequer Bills, and other Loan Books, the Vouchers of Public Accounts, the Collector's Accounts from every district in Ireland; the Quit-Rent Receipt Books, the Sheriffs' Accounts, with some Ancient Accounts of the Hanaper, First Fruits, Farmers of Revenue, Subsidies, Poll Tax, &c. The *Prerogative Office;* the *First-Fruits Office: Surveyor-General's Office.* (*Reports of the Commissioners on the Public Records of Ireland.*)

The most important Public Records may be enumerated as follows:—

Great Roll of the Exchequer, from Hen. II., 1154, to Geo. III., 1760.
Comptroller's or Chancellor's Roll, 11 Hen. II.—Geo. III., 1760 (now deposited in the British Museum).
Rotuli Curiæ Regis, Ric. I., 1194—Hen. III., 1216.
Fines, Concords, Writs of Covenant, Feet of Fines, &c., 25 Hen. II., 1179—Wm. IV., 1833.
Charter Rolls, John, 1199—Hen. VIII., 1509.
Norman Rolls, John, 1200—Hen. V., 1412.
Patent Rolls, John, 1201—present time.
Close Rolls, John, 1204—Geo. II., 1727.
Liberate Rolls, John, 1200—Edw. IV., 1460-1.
Fine Rolls, John, 1204—Chas. I., 1625.
French Rolls, Hen. III., 1232—Edw. IV., 1460-1.
Gascon Rolls, Hen. III., 1242—Hen. VI., 1422.
Scotch Rolls, Edw. I., 1291—Edw. IV., 1460-1.
Roman Rolls, Edw. I., 1305—Edw. IV., 1460-1.
Statute Rolls, (afterward the Parliament Roll,) Edw. I., 1277—Edw. IV., 1460-1.
Rolls of Parliament, Edw. I., 1272—Ric. III., 1483; Statutes, Hen. VII., 1485—Geo. II., 1727.
Petitions in Parliament, Edw. I., 1272—Edw. IV., 1460.
Journals of the House of Lords, Hen. VIII., 1509—to present time.
Journals of the House of Commons, Hen. VIII., 1509.
Summons and Returns to Parliament, Edw. I., 1288—Hen. VI., 1422; 33 Hen. VIII.—present time.
Original Acts of Parliament, 12 Hen. VII.—Wm. IV., 1830.
Inquisitiones post Mortem, or Escheats, Hen. III., 1216—Chas. I., 1625.
Inquisitiones ad quod damnum, Edw. II., 1307—Hen. VI., 1422.
Coronation Rolls, Edw. II., 1307—(series imperfect)—Geo. II., 1727.
Treaty Rolls (irregular series), Edw. V., 1483—James II., 1684-5.
Confirmation Rolls, Ric. III., 1483—Commonwealth, 1649.
Dispensation Rolls, 37 Eliz.—Geo. II., 1727.
Rolls of Pardons, Ric. III., 1483—Eliz. 1558.
Judgment or Decree Rolls of Chancery, 25 Hen. VIII.—Geo. II., 1727.
Surrender and Specification Rolls, Chas. II., 1648-9—present time.
Privy Seals and Signet Bundles, Bills, and Writs, Edw. I., 1272—present time.
Signed Bill Bundles, Hen. VII., 1485—present time.
King's Bench Judgments, &c. inrolled, Edw. I., 1272—present time.
Common Pleas Judgments inrolled, Edw. I., 1272—present time.
Placita Terræ of the Common Pleas, Eliz., 1558—present time.
Pleas of the Forest, Hen. III., 1216—James II., 1684-5.
Memoranda Rolls of King's Remembrancer, Hen. III., 1216—present time.
Originalia, Hen. III., 1216—Geo. III., 1760.
Miscellaneous Records of the King's Remembrancer, Ric. I., 1189—Geo. III., 1760.
Court of Augmentations, Ministers' Accounts, Hen. VIII., 1509—Chas. II., 1648.
Inrolments of Judgments, &c. in the Exchequer of Pleas, Hen. III., 1216—present time.
Placita de Assisis, 6 Ric. I.—Edw. V., 1483.

The preceding list exhibits generally, with a few exceptions hereafter noticed, the commencement of the chief and most valuable of our national records, and the periods over which they extend, from the time of Richard I., the boundary of 'legal memory.'

In the above list we have not included Domesday Book, the choicest of all our record treasures, and the corner-stone of our topographical history. The record itself has been most faithfully printed, and copiously described by Sir Henry Ellis. [DOMESDAY BOOK.] There are two abridgements of Domesday Book among the exchequer records, made probably about the time of Henry III. Subsequent territorial surveys, the Hundred Rolls, Extenta Manerii, Testa de Nevill, and Pope Nicholas' Taxation temp Ed. I., the Domesday of Wales, and Nonæ Rolls temp. Ed. III., King Henry VIII.'s Surveys, and Parliamentary Surveys of the Commonwealth, are excluded, because they form no consecutive series like the above.

The Great Roll of the Exchequer, or Pipe Rolls, or Rotuli Annales, being yearly accounts of the king's revenue, are conjectured to have begun with the Conqueror. Some evidence exists to establish that they probably extended over the whole reign of Henry I., though we know at present but of a single roll, the thirty-first year of that reign, which the Record Commission published under the editorship of Mr. Hunter. Excepting the rolls for the 1st of Henry III. and 7 Henry IV., the series from the 2nd of Henry II. is complete. Madox speaks of them as 'Recorda omnium quæ in Archivis Regis usquam me memini, splendidissima, post Rotulum censualem quem Librum Domesday vocant; quin ei æquiparanda.'

The series of Fines, being records of the transfer of lands, &c., extends unbroken, and almost unchanged in form, from the 25 Henry II. to the end of the year 1833, when this species of conveyance was abolished. [FINES.] Since the 16 Edward I. they have been delivered from time to time into the 'treasury' of the exchequer. Those in the Chapter-house and those lately kept by the Custos Brevium of the Common Pleas will shortly be united, and will present a series of records, like the Pipe Rolls and Rolls of the Curiæ Regis, unrivalled in all Europe. The Cartæ Antiquæ in the Tower are transcripts of charters descending from the Saxon times to Henry III. They are hardly to be considered as part of the splendid series of chancery rolls commencing in King John's reign. In noticing the chancery rolls it is quite superfluous to do more than refer the reader to the prefaces which Mr. Thomas Duffus Hardy has attached to his editions of the earliest close and patent rolls. If we were to continue to particularise documents of age and interest, such as the Norman pipe-roll of Henry I., the 'Rotulus de Dominabus, temp. Henry II.' (which was printed by Mr. Stacey Grimaldi, in 1830), the Red Book of the Exchequer, containing the laws of the Conqueror and those ascribed to Henry I. (which has been fully catalogued by Mr. Hunter, in the *General Report of Commissioners on Public Records*, 1837, p. 165), the Misæ and Præstita rolls of King John, or the Magnæ Chartæ of our kings, which were not inrolled in a systematic series until 1278, we should never conclude the subject. We therefore refrain from further specifications, and conclude this article with a list of the various publications of the Record Commissioners.

1. Domesday Book: seu Liber censualis Willielmi Primi, Regis Angliæ.
   Domesday Book, 2 vols. folio, 1783.
   Additamenta, consisting of the Exon Domesday, Inquisitio Eliensis, the Winton Domesday and the Boldon Book, and Indices, 2 vols. folio, 1816.
2. Statutes of the Realm, 9 vols. fol.; Alphabetical Index, 1 vol.; Chronological Index, 1 vol.: in all eleven volumes.
3. Fœdera, Conventiones, Litteræ, et cujuscunque generis Acta Publica, inter reges Angliæ, et alios quosvis Imperatores, Reges, Pontifices, Principes vel Communitates (being a new edition of Rymer's Fœdera).
4. Calendarium Rotulorum Patentium in Turri Londinensi (from John to Edward IV.), 1 vol. fol.
5. Calendarium Rotulorum Chartarum et Inquisitionum ad quod damnum (from John to Henry VI.), 1 vol. fol.
6. Calendarium Inquisitionum ad quod damnum (from 1 Edward II. to 38 Henry VI.).
7. Placitorum, in domo Capitulari Westmonasteriensi Asservatorum—abbreviatio, temporibus regum Richard I., Johannis, Henry III., Edward I. et Edward II., 1 vol. fol.
8. Testa de Nevill; sive liber Feodorum in Curia Scaccarii, temp. Henry III. et Edward I., 1 vol. fol.
9. Rotulorum Originalium in curia Scaccarii abbreviatio temporibus regum Henry III., Edward I., II., et III., 1 vol. fol.
10. The Parliamentary Writs, and Writs of Military Summons; together with the Records and Muniments relating to the suit and service due and performed to the King's High Court of Parliament and the Councils of the Realm, or affording evidence of attendance given at Parliaments and Councils, vol i.; vol. ii. divisions 1 and 2 and 3, fol.
11. Rotuli Hundredorum, temp. Henry III. et Edward I. in Turri Lond., et in Curia receptæ Scaccarii Westm. Asservati, 2 vols. fol., 1812.
12. Placita de Quo Warranto, temporibus Edward I. II, et III. in Curia Scaccarii Westm. Asservata, 1 vol. fol, 1818.
13. Calendarium Inquisitionum post Mortem, sive Escaetarum, 4 vols. fol. (from Henry III. to Edward IV.).
14. Nonarum Inquisitiones in Curia Scaccarii temp Regis Edwardi III., 1 vol. fol., 1807.
15. Taxatio Ecclesiastica Angliæ et Walliæ, Auctoritate P. Nicholai IV., circa A.D. 1291, 1 vol. folio.
16. Valor Ecclesiasticus, temp. Henry VIII., Auctoritate Regia institutus, 6 vols., folio.
17. Calendars of the Proceedings in Chancery in the Reign of Queen Elizabeth; to which are prefixed Examples of earlier Proceedings in that Court, namely, from the Reign of Richard II. to that of Queen Elizabeth inclusive, from the originals in the Tower, 3 vols., folio.
18. Ducatus Lancastriæ Pars Prima:—Calendarium Inquisitionum post Mortem, &c., Temporibus Regum Edward I., Edward III., Richard II., Henry V., Henry V., Edward IV., Henry VII., Henry VIII., Edward IV., Regin. Mar., Phil. et Mar., Eliz., Jac. I., Car. I.
   Pars Secunda:—A Calendar to the Pleadings, &c. in the reigns of Henry VII., Henry VIII., Edward VI., Queen Mary, Philip and Mary, and Elizabeth, 3 vols., fol.
19. A Catalogue of the Manuscripts in the Cottonian Library deposited in the British Museum, 1 vol., folio, 180[illegible].
20. A Catalogue of the Harleian Manuscripts in the British Museum, 4 vols., fol., 1808-1812.
21. A Catalogue of the Lansdowne Manuscripts, 1 vol., fol.
22. The Acts of the Parliament of Scotland, vol. ii. to vol. xi.; from 1424 to 1707.
23. Registrum Magni Sigilli Regum Scotorum, in Archivis Publicis asservatum, A.D. 1306-1424, 1 vol. fol., 1814.
24. Roluli Scotiæ in Turri Londinensi, et in Domo Capitulari Westmonasteriensi Asservati, 2 vols., fol.
25. Inquisitionum ad Capellam Domini Regis retornatarum quæ in Publicis Archivis Scotiæ adhuc servantur Abbreviatio, 3 vols, fol.
26. A General Introduction to Doomsday Book, 2 vols., 8vo.
27. Rotulus Litterarum Patentium 7 John: Transcripta Litt. Pat. Hiberniæ, temp. Henry V. and VI. Placita [illegible] Henry III., 8vo.
28. Rotuli Litterarum Clausarum ab anno 1204 [illegible] annum 1224, 1 vol.
29. Rotuli Litterarum Patentium, A.D. 1201-1216, fol
30. The Chancellor's Roll, or Antigraph of the Great Roll of the Pipe, 3 John, 8vo.
31. Rotulus Magnus Pipæ de anno 31 Henry I., commonly called the Roll of Stephen, 8vo.
32. Proceedings and Ordinances of the Privy Council [illegible] the reigns of Richard II., Henry IV., V., VI., 7 vols., 8vo.
33. Rotuli Normanniæ: John and Henry V., 8vo.
34. Excerpta e Rotulis Finium; Henry III., 2 vols., 8vo.
35. Rotuli de Oblatis et Finibus; John, 1 vol., 8vo.
36. Fines sive Pedes Finium, sive finales Concordiæ [illegible] Curiâ Domini Regis, A.D. 1195-1214, 8vo.
37. Rotuli Curiæ Regis Ric. I. et John, 2 vols., 8vo.
38. An Account of the most important Records of Great Britain, by C. P. Cooper, 2 vols., 8vo.
39. Selections from the Miscellaneous Records of [illegible] King's Remembrancer of the Exchequer, fol. (not [illegible] issued).
40. Docquets of Commissions, Grants of Honors, Pardons and other patents of Charles I. while at Oxford, 1642-46, [illegible] (not yet issued).
41. Antient Inventories and Calendars of the Treasury [illegible] the Exchequer, from Edward III. to Henry VIII., 3 vols., 8vo.
42. Documents elucidating the Ancient H[illegible] land, Alexander III. to Robert I., 1 vol., 8vo. [illegible]
43. The Charter Rolls of John, 1 vol., fol. [illegible]
44. Antient Laws and Institutes of [illegible] laws enacted under the Anglo-Saxon[illegible] to Canute, with an English tran[illegible] laws called Edward the Confe[illegible] the Conqueror; and those [illegible] Monumenta Ecclesiastica [illegible] the eleventh century; [illegible] Anglo-Saxon Laws, 1 v[illegible]

The printing of a [illegible]

was in progress when the Record Commission dropped. What these were may be seen in the Commons' *Report on the Record Commission, App.*, p. 782.

RECOVERY, COMMON. A common recovery was a judgment in a fictitious suit, in which the tenant of the freehold was the defendant; and the judgment was given in consequence of default made by the person who was last vouched, that is, summoned to warranty in such suit. It was used for the purpose of barring estates tail and all remainders and reversions expectant thereon.

A common recovery was in the form of a judgment obtained in a real action, and accordingly the mode of proceeding was the same as in an action not fictitious. The plaintiff in the action, or demandant, who sought to recover the lands, sued out a writ or præcipe, at it was called, from the words of the writ (Praecipe A, the tenant, quod juste, &c. reddat B, the lands in question) against the person who had the freehold of the estate, and who was called the tenant to the præcipe. When the recovery was suffered by a tenant in tail in possession, he might himself be the tenant to the præcipe. The tenant of the freehold appeared to the writ by himself or by his attorney; but instead of defending his title, he vouched (vocavit) some other person who was supposed to be bound to warrant the tenant's title, and he prayed that the person so vouched (the vouchee) might defend the title so warranted, or that, if he could not, he might give the tenant lands of equal value with those which he might lose by failure of the warranty. The vouchee, having appeared, undertook the defence of the tenant's title, but he purposely failed to do so, and on his default the court gave judgment, which was that the demandant or recoveror should recover the lands against the tenant, and that the tenant should recover against the vouchee lands of equal value. Such lands were called the recompense or recovery in value. By the first judgment the demandant obtained the fee simple of the estate. The whole proceeding being a fiction, it was usual to make the common crier of the Court of Common Pleas the vouchee, who was hence called the common vouchee. This proceeding was called recovery with single voucher; but there might be recovery with double or treble voucher, in which case judgment was given against the several vouchees. In the case of double voucher, the tenant in tail conveyed an estate of freehold to some person, against whom the demandant brought the writ or præcipe. The tenant to the præcipe vouched the tenant in tail, who vouched over the common vouchee, who of course made default, and judgment was accordingly given for the demandant against the tenant to the præcipe, for the tenant to the præcipe against the tenant in tail, and for him against the common vouchee.

On judgment being given, a writ of habere facias seisinam was sued out, which was directed to the sheriff of the county, who was thereby ordered to put the demandant in possession of the lands in question. In practice the writ of seisin was not executed, but it was necessary that it should be returned, and when it was returned the recovery was complete.

The principal circumstances have been mentioned which were necessary to make a good recovery, and a defect in any one of them, or in any of the proceedings, might vitiate the recovery. One of these circumstances of the greatest practical importance was the making a good tenant to the præcipe; for unless the person against whom the writ was brought was actual tenant of the freehold, there could be no good recovery. It was however sufficient if he acquired the freehold at any time before judgment was given in the suit; and by 14 Geo. II., c. 20, § 6, it was sufficient if he acquired the freehold after judgment and the award of the writ of execution.

When the person who wished to suffer the recovery was tenant in tail in possession, the writ might be directed to him (as already observed), and he would be the tenant to the præcipe. But it was usual for the tenant in tail to be vouched, in which case some other person must be the tenant to the præcipe; and for the following reason:—The validity of the recovery was founded on the doctrine that the estate which the tenant in tail obtained by virtue of the warranty in lieu of that which he lost by the vouchee's default, would descend to the heirs in tail, just as the estate would have done which the tenant in tail had lost. It is true that the recompense could not extend to the person entitled to the reversion, nor to contingent interests; but this defect, which would have been fatal if the transaction had been real, was never considered to impair the efficacy of the fictitious proceeding. But it was a settled principle that the estate obtained by way of recompense would only follow the course of descent of that estate of which the tenant in tail was seised at the time of the recovery; and therefore if the tenant in tail at the time of the recovery was not seised of an estate tail according to the form of the original gift, the recompense in value would descend according to the estate which he had at the time of the recovery, and not according to the original gift; and consequently those who claimed under the original gift would not be barred because they obtained no recompense in value. It might happen in various ways that the estate which the tenant in tail had at the time of the recovery was not the estate tail according to the original gift. To prevent this inconvenience, the tenant in tail gave an estate of freehold to some person in order to make him a good tenant to the præcipe. This was done in various ways, but generally by bargain and sale enrolled, or by lease and release. The instrument which transferred the estate of freehold generally contained the declaration of the uses of the recovery, as hereinafter mentioned. The action being brought against the tenant to the præcipe, he vouched the tenant in tail, who vouched over the common vouchee. As the tenant in tail confessed the warranty, and undertook the defence of the action, he was considered to submit all his rights in the land to the effect of the recovery, which was called a recovery with double voucher. If the tenant in tail had only a vested estate in remainder, he could not make a tenant to the præcipe, and it was therefore necessary, in order to suffer a recovery, that the first person who had an estate of freehold in the lands should consent to make a tenant to the præcipe. But by 14 Geo. II., c. 20, it was not necessary for the tenant in tail to have the concurrence of the immediate freeholder, if he was merely a lessee for life subject to the payment of a rent; but if the estate tail was preceded by any estate or estates of freehold, besides that of the lessee for life, the concurrence of the holder of such estate, or of the first of such estates, was necessary. In many of the questions which have arisen on the validity of recoveries, the question has been whether there was a good tenant to the præcipe.

A common recovery was generally suffered in the Court of Common Pleas only; but common recoveries of lands in the counties palatine of Durham and Lancaster were suffered in the respective courts of those counties. A recovery of lands held in antient demesne was suffered in the courts of the manors of which such lands were held; and in many manors a recovery might be suffered in the customary courts of such manors of which the copyholds were parcel.

The writ of entry, as appears from its form, was not generally adapted to incorporeal hereditaments, yet such hereditaments were supposed to be included in it for the purpose of suffering a recovery. Though a rent charged on lands might be the subject of a recovery, a rent charged on personal estate could not. The interest, of which a recovery was suffered, might be an undivided share. As an equitable estate may be entailed, it was held that a common recovery suffered by a cestui que trust in tail in possession would bar such estate tail and all equitable remainders and reversions dependent upon it. In recoveries of this kind it was necessary that there should be an equitable tenant to the præcipe.

The effect of a common recovery differed in several respects from that of a fine. A fine was originally introduced as a mode of alienation by record, and its effect in barring entails was owing to the stats. 4 Hen. VII., c. 24, and 37 Hen. VIII., c. 19, which were not made till several centuries after the introduction of fines. A common recovery had no absolute effect after a fixed number of years, as a fine had; but inasmuch as the recoveror acquired an estate in fee simple, it had effects very different from those of a fine. A common recovery duly suffered defeated all the remainders and reversions expectant on the estate tail, and also all shifting uses and executory devises expectant upon it, provided the recovery was suffered before the contingency happened on which the executory devise was to take effect. A fine had the effect of destroying the estate tail by converting it into a determinable fee. Accordingly if the tenant in tail who had the immediate remainder or reversion in fee barred his estate tail by a fine, he acquired a base fee, which was merged in the remainder or reversion, which thus became an estate in possession, and subject to all the charges and estates made and created by the person from whom the tenant in tail derived his remainder or reversion. Besides this, it would be necessary for such person on any occasion of selling his land, to make out his title to the remainder or reversion. A common recovery operated by enlarging the estate tail into a fee, and thus absolutely destroying all remainders and reversions, but it confirmed all prior estates or charges made by the tenant in tail who suffered the recovery. Thus if a tenant in tail made a lease not permitted by the stat. 32 Henry VIII., or acknowledged a judgment, and then suffered a common recovery, this would be a confirmation of those charges, which, if there had been no recovery, would have had no effect against the issue in tail.

The origin of recoveries is referred to the decision in Taltarum's case, 12 Edw. IV., in which, though it was declared that the estate tail in question was not barred by the recovery suffered, the reason that was given for the decision admitted that it might have been barred by a recovery. In Taltarum's case, the tenant who suffered the recovery was not seised of the estate tail under which the issue in tail claimed, but he was seised of a different estate at the time of the recovery being suffered.

Those persons only were barred by a common recovery who were parties to it, and also the issue in tail, remainder-men, and reversioners, and all persons who claimed under any limitations expectant on or to take effect after the determination of the estate tail. But no estates or interests prior to the estate tail were affected by the recovery.

Recoveries were impeachable for various reasons, such as defect of jurisdiction in the court in which they were suffered, informality in the proceedings, and the want of a good tenant to the præcipe.

The immediate object of the recovery, as above observed, was to give an estate in fee simple to the recoveror; but the ultimate object was to commonly settle the estate to new uses, which were generally declared by the instrument which gave the estate of freehold to the tenant to the præcipe.

By 3 & 4 Will. IV., c. 74, fines and recoveries are abolished, formal defects in those already levied or suffered are cured, and more simple modes of assurance are substituted. The substitution provided by this Act for the barring of an estate tail and all estates and interests to take effect after the determination of or in defeasance of the estate tail, is an assurance by deed to be enrolled in the court of chancery within six calendar months after its execution.

RECRUITING is the act of raising men for the military or naval service, either to augment the numerical strength of an army or fleet by new levies, or to make good the complement of any regiment or ship. The term may be used when men are obtained in any of the ways which the customs of nations have sanctioned or the necessities of certain times may have required; but among military men it is employed when officers, especially appointed for the purpose, engage men by the offer of bounties to enter as private soldiers into particular regiments. The officers, commissioned and non-commissioned, while so employed, are said to be on the recruiting service; but the actual engaging of men as recruits is called enlistment; and the laws relating to this subject have been already noticed. [ENLISTMENT.]

Formerly private persons were allowed to enlist men for the army in any way that they might think best; but these having sometimes adopted, in order to procure recruits, violent and illegal means by which the public indignation was excited, the government in 1802 took the management of the recruiting department into its own hands; and now, by a clause in the Mutiny Act, any person advertising or opening an office for recruits without authority in writing from the adjutant-general or the directors of the East India Company is liable to the penalty of twenty pounds.

In order to produce uniformity in the system of recruiting, and to ensure the employment of legal means only in obtaining men, the supreme control of this branch of the military service was vested in the adjutant-general of the army, and both Great Britain and Ireland were divided into several recruiting districts. To each of these was appointed an inspecting field-officer; an adjutant, whose duty it is to ascertain, in respect of stature and bodily strength, the fitness of any recruit for the service; a paymaster, and a surgeon, the latter of whom is to report concerning the health of the recruit. Under the inspecting field-officer there are several regimental officers, who are stationed in the principal towns of the different districts in order to superintend the non-commissioned officers appointed to receive the applications of the persons who may be desirous of entering the service.

England and Wales together are, for the recruiting service, divided into five districts, of which the first comprehends all the counties lying north of the Humber: the head-quarters for this district are at Leeds, which is the station of the field-officer, and there are superintending officers in that town, and also at York and Bradford. The second district comprehends North Wales and the inland counties eastward as far as Derbyshire inclusive; the head quarters are at Liverpool, and there are superintendents at that place, and also at Manchester and Sheffield. The third district comprehends South Wales and the inland counties eastward as far as Lincolnshire inclusive; the head-quarters are at Coventry, and there are superintendents at Leicester, Birmingham, Shrewsbury, Nottingham, Lincoln, and Stamford. The fourth district includes the south-western counties of England as far as Hampshire; its head-quarters are at Bristol, and there are superintendents at Gloucester, Salisbury, and Exeter. Lastly, the fifth district comprehends all the eastern counties south of Lincolnshire; the head-quarters are at Westminster, and there are superintendents in London, at Reading, Ipswich, and Norwich.

The head-quarters of the recruiting department in Scotland are at Glasgow, and there are superintending officers in that city, at Edinburgh, Perth, Aberdeen, and Inverness.

Ireland is divided into three recruiting districts. The head-quarters of the first or northern district are at Newry, and, besides the superintendent at that place, there are others at Enniskillen, Belfast, and Derry. The head-quarters of the central district are at Dublin, and there are superintendents also at Athlone and Cavan. Lastly, the head-quarters of the third or southern district are at Cork, and there are superintending officers at Limerick and Kilkenny.

The chief recruiting depôt for the East India Company's forces is at Chatham, and there are superintending officers in London, at Liverpool, Dublin, and Cork.

In order to procure recruits, a serjeant or other non-commissioned officer mixes, in country places, with the peasantry at their times of recreation; and, in towns, with artisans who happen to be unemployed, or who are dissatisfied with their condition; and, by address in representing whatever may seem agreeable in the life of a soldier, or by the allure of a bounty, occasionally induces such persons to enter the service.

The reports concerning the fitness of a recruit for military service are finally submitted for approval to the inspecting field-officer of the district, except when the distance of the head-quarters from the place where the recruit is enlisted is such that it would be more convenient to send the latter to the depôt of the regiment to which he is to belong: in that case the officer commanding at the depôt is especially authorised to sanction them.

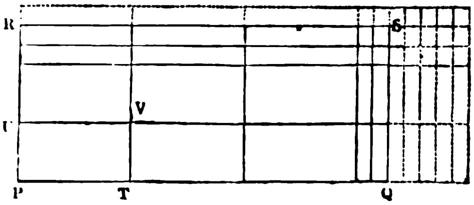
Officers employed on the recruiting service are not allowed to interfere with one another in the performance of their duties; particularly, no one is permitted to use any means in order to obtain for his own party a man who has already taken steps by which he may become engaged to another.

RECTANGLE (or right angled), the name given to any figure of which all the angles are right angles. Hence the figure, having as many right angles as sides in the sum of its angles, must be foursided; for none but a foursided figure has the sum of its angles equal to four right angles. It is unnecessary to give a diagram of the most common of all the forms of art; the page of this book may serve as an instance.

The properties of the rectangle, to which it owes its importance in a mathematical point of view, consist of one which it shares in common with all parallelograms, and one which marks it as the most simple of parallelograms. Every parallelogram, and the rectangle among the rest, may be divided in an infinite number of ways into parallelograms having the same angles as the original parallelogram; and if any parallelogram be divided into others by lines drawn parallel to one only of the sides, the smaller parallelograms bear to the whole the same proportion as their several bases bear to the whole base. Also, the area of a rectangle may be immediately deduced from nothing but the length of its two sides. If as a superficial unit we choose a rectangle having the sides A and B, it may immediately be told how many times and parts of times any other rectangle contains the unit. Measure one side, and see how many times it contains A (say $2\frac{3}{4}$); measure the other side, and see how many times it contains B (say $3\frac{2}{7}$); then the product of $2\frac{2}{3}$ and $3\frac{2}{7}$, or

$$\frac{8}{3}\times\frac{23}{7}, \text{ or } \frac{184}{21}, \text{ or } 8\frac{16}{21},$$

is the number of times which the rectangle to be measured contains the unit rectangle. This may be shown as follows:—



Let PQRS be the rectangle to be measured, and PTUV the unit rectangle, PU being A, and PT being B. The rectangle RQ is so drawn that PR contains $2\frac{2}{3}$ of A, and PQ contains $3\frac{2}{7}$ of B. The whole rectangle is obviously divided into six rectangles of the size of PV: six at the top, each of which is one-third of PV; four on the right, each of which is one-seventh of PV; and four higher up on the right, each of which is the twenty-first part of PV. We have then, on the whole, PV repeated

$$6+\frac{6}{3}+\frac{4}{7}+\frac{4}{21}, \text{ or } \left(2+\frac{2}{3}\right)\left(3+\frac{2}{7}\right) \text{ times.}$$

In practice it is most convenient to make PT and PU equal to one another, and equal to the unit used in measuring lengths. Hence the rule for finding the area of a rectangle is: multiply together the number of linear units in the two sides, and the result is the number of square units (or squares on the linear unit) in the rectangle. This rule is abbreviated as follows: the product of the sides of a rectangle is the area; an abbreviation which often confuses the mind of a beginner, who imagines that two *lines* can be multiplied together [MULTIPLICATION], and that the rectangle, that is, the very shape of the rectangle, is the product; a mistake precisely that of a person who should imagine that the very silver of ten shillings could be multiplied by seven yards of stuff, and that the product could be seventy shillings. Now seven yards of stuff at ten shillings a yard certainly cost as many shillings as there are units in 7×10; and a rectangle whose sides are seven and ten feet certainly contains as many square feet as there are units in 7×10; but seven feet can no more be multiplied by ten feet than seven shillings by ten yards of silk.

When however given words imply a false proposition, there are two modes of proceeding, either to alter the words or to alter the meaning of the words. If a person should be so accustomed to talk of multiplying concrete quantities together that he cannot avoid it, he must learn to define multiplication as the finding of a fourth proportional to three concrete quantities, the first of which is a concrete unit. If this be the meaning of multiplication, then six yards and three yards can be multiplied together; for as one yard is to three yards so is six yards to eighteen yards, and eighteen yards is the product. But this product is a line, not an area.

The pertinacity with which some writers still persist in calling the product of two lines the area of a rectangle (not only as a practical rule of mensuration, in which it is a desirable mode of expression, but in matters of reasoning) is the result of a long-continued habit formed in the first instance by the study of the Greek writers. For though these do not confound the product with the area; yet, on account of the deficiencies of their algebraical system, they used the area instead of the product, and gave the names of spaces to the results of numbers. Thus the product of two numbers was called plane, that of three equal numbers solid, that of two equal numbers a square, that of three equal numbers a cube, and the difference of two square numbers a gnomon. To these we may add the titles of polygonal, pyramidal, &c. numbers [NUMBERS, APPELLATIONS OF], and others which it is needless to mention. All arithmetical propositions were made to take the form of geometrical ones: thus to multiply two numbers was to form the rectangle of two given lines; to divide one number by another was, given the area of a rectangle and one of its sides, to find the other side. We have seen it stated that the word παραβολή (parabola) was sometimes used for quotient, and, it was said, in Diophantus. We cannot find it there, though it may be used by the scoliast, whom we have not examined. But most certainly the explanation of the meaning of parabola, as applied to the well-known curve, comes from some such signification. The term parabola means a thing laid near to or by the side of another; for comparison, for instance, as in the common word parable, or for any other purpose. Now in the conic section in question the square on the ordinate being converted into a rectangle one of whose sides is the abscissa, the remaining side (being that which must be laid by the first side before the figure can be drawn, or the παραβολη) is always of the same length. If modern writers had applied the term parabola to this remaining side, they would probably have called the curve an isoparabolic section; but the Greeks, who called the curve in which a certain defect is always in the same proportion to the whole by the simple name of defect (ellipse), and one having the same sort of excess by the simple name of excess (hyperbola), called the isoparabolic curve simply a parabola. Montucla supposes that as ellipse means defect, and hyperbola excess, parabola must mean equality; but even supposing that an etymological justification of this meaning could be made, that which is defect in the ellipse and excess in the hyperbola does not become equality in the parabola.

Of the geometrical system which pervaded the Greek arithmetic, we have permanently retained only the words square and cube; rectangle was frequently used for product, but is rarely at present. These words are the causes of much confusion to students who begin to apply arithmetic to geometry. Thus in algebra the square of a sum is equal to the sum of the squares of the two quantities, together with twice their product. In geometry the square of the sum of two lines is equal to the sum of the squares on the lines, together with twice their rectangle. Those who are not made to see clearly the distinction of these propositions confound them together. A sufficient distinction might be made by a little variation in phraseology: speak of the square *on* a line, and the square *of* a number. Thus 49 is the square of 7: erect two perpendiculars each equal to AB at the two extremities of AB, and joining their other extremities completes the square *on* AB. It is already customary to speak of the rectangle whose contiguous sides are AB and AC, as the rectangle *under* AB and AC.

The second book of Euclid is devoted to the properties of the rectangle, as they arise from subdivision into other rectangles. Some persons advocate what is called the arithmetical proof of these propositions, namely, the substitution of the analogous properties of numbers for those of rectangular spaces. This question must be settled in the same manner as that of PROPORTION, and the remarks in that article apply. If all pairs of lines were commensurable, no objection could be taken against the rigour of the substitution; but unless a theory of incommensurables, and a modification of the definition of multiplication to suit them, be formally introduced, the method of Euclid is sound, and the substitute for it unsound; though proper enough for the adoption of those who, as explained in the article cited, only wish to become mathematicians to a certain number of decimal places.

RECTIFICATION means the finding of a straight line equal in length to an arc of a curve [ARC], and is analogous to the term quadrature, as applied to finding its area; for in like manner as an area is considered to be known when a square equal to it is exhibited, so the length of an arc is known when a straight line equal to it is exhibited.

Of the celebrated problem of the rectification of the circle we have said enough under QUADRATURE OF THE CIRCLE, in which article it appears that the rectification gives the quadrature; so that the latter problem was generally attempted through the former.

RECTOR, RECTORY. [BENEFICE.]

RECULVER. [KENT.]

RECURRING SERIES. By a recurring series is meant one of the form

$$a_0+a_1x+a_2x^2+a_3x^3+a_4x^4+\dots$$

ad infinitum, in which the coefficients a_0, a_1, &c. can each be expressed by means of certain preceding coefficients and constants in one uniform manner; and it is usual to consider only such series as will admit of a linear relation (or one in which only first powers of coefficients enter): thus the series

$$1+x+4x^2+13x^3+53x^4+172x^5+\dots$$

follows the linear law $a_n=3a_{n-1}+a_{n-2}$ $(4=3.1+1,\ 13=$

3.4+1, 53=3.13+4, &c.), and is what is commonly called a recurring series, though the following—

$$1+x+2x^2+5x^3+29x^4+866x^5+\ \&c.,$$

in which $a_n = a_{n-1}^2 + a_{n-2}^2$ is equally recurring, according to the definition. The recurrence alluded to is not that of terms, but of method of determining terms; and it would be desirable that the series which are usually called recurring should be *linearly* recurring series, while any in which there is really recurrence (of law) should be called recurring.

Every linearly recurring series is the development of an algebraic function with a rational and integral numerator and denominator, and every such function can be developed into a linearly recurring series. Thus, taking the first series mentioned, in which $a_n = 3a_{n-1} + a_{n-2}$, we have

$$a_2 x^2 = 3a_1 x^2 + a_0 x^2$$
$$a_3 x^3 = 3a_2 x^3 + a_1 x^3$$
$$a_4 x^4 = 3a_3 x^4 + a_2 x^4,\ \&c.$$

Let S be the sum of $a_0 + a_1 x +$, &c., ad infinitum. Then the preceding obviously gives

$$S - a_0 - a_1 x = 3x\,(S - a_0) + x^2 S;$$
$$\text{or, } S = \frac{a_0 + (a_1 - 3a_0)\,x}{1 - 3x - x^2}$$

We have here the value of any series in which this law of recurrence prevails for all terms after the second; and it cannot prevail before, since two terms must exist before a third can be expressed. In the case we chose, $a_0 = 1$, $a_1 = 1$, whence the function of which the series was the development is $(1-2x) \div (1-3x+x^2)$.

Generally, a linear recurring series having the law of recurrence

$$a_n = p_1\, a_{n-1} + p_2\, a_{n-2} + \ldots\ldots + p_t a_{n-t}$$

is the development of the function

$$\frac{A_0 + A_1 x + A_2 x^2 + \ldots\ldots + A_{t-1} x^{t-1}}{1 - p_1 x - p_2 x^2 - \ldots\ldots - p_t x^t}$$

where $A_0 = a_0,\ A_1 = a_1 - p_1 a_0,\ A_2 = a_2 - p_1 a_1 - p_2 a_0, \ldots\ldots$

$$A_{t-1} = a_{t-1} - p_1 a_{t-2} - p_2 a_{t-3} - \ldots\ldots - p_{t-1} a_0,$$

from which the inverse theorem may easily be derived, namely, that

$$\frac{A_0 + A_1 x + A_2 x^2 + \ldots\ldots + A_{t-1} x^{t-1}}{B_0 + B_1 x + B_2 x^2 + \ldots\ldots + B_{t-1} x^{t-1} + B_t x^t}$$

can be developed into $a_0 + a_1 x + a_2 x^2 +$ &c., in which the law of recurrence (n not being $<t$) is as follows:—

$$B_0\, a_n + B_1\, a_{n-1} + B_2\, a_{n-2} + \ldots\ldots + B_t\, a_{n-t} = 0,$$

and the terms up to a_{t-1} are determined by

$$A_0 = B_0 a_0,\ A_1 = B_0 a_1 + B_1 a_0,\ A_2 = B_0 a_2 + B_1 a_1 + B_2 a_0$$
$$\ldots\ldots A_{t-1} = B_0 a_{t-1} + B_1 a_{t-2} + \ldots\ldots + B_{t-1} a_0.$$

Those who understand the theory of generating functions will see that the generating function can thus be found to the solution of any linear equation of differences. Some use may thus be made of recurring series in various questions of the theory of probabilities; but, generally speaking, this species of series is not of the most useful kind, connected as it is with the rational and integral function of algebra, which is of little application compared with the irrational and transcendental function. [SERIES.]

The most simple mode of finding the law of the terms of a recurring series is by the solution of the equation of differences, which expresses the relation of the coefficients. This may be verified by decomposing the function which is developed into the series into fractions with denominators of the first degree, according to the common method used in the integral calculus, and expanding each fraction separately.

RECURVIROSTRA. [AVOSET.]

RECUSANTS are persons who refuse or neglect to attend divine service on Sundays and holidays, according to the forms of the Established Church. Before the Reformation, ecclesiastical censures were directed at different times by provincial councils against those who absented themselves from the services of the church. But the noticing of recusancy in the temporal courts, and probably the use of the term itself, cannot be traced higher than the sixteenth century. By the 1 Eliz., c. 2, it is enacted 'that all persons shall diligently and faithfully, having no lawful or reasonable excuse to be absent, endeavour to resort to their parish church or chapel accustomed, or upon reasonable let (hindrance) thereof, to some usual place where common prayer, &c. shall be used, in time of such let, upon every Sunday and other days ordained and used to be kept as holy days, and then and there to abide orderly and soberly during the time of the common prayer, preaching, and other service of God there to be used and ministered, upon pain of punishment by the censures of the church, and also upon pain that every person so offending shall forfeit for every such offence twelve pence.' By 23 Eliz., c. 1, it is enacted, 'that every person above the age of sixteen years who shall not repair to some church, chapel, or usual place of common prayer, but forbear the same, contrary to the tenor of the statute of 1 Eliz., c. 2, and being thereof lawfully convicted, shall forfeit for every month which he or she shall so forbear, twenty pounds.' This statute has been held not to dispense with the forfeiture imposed by the former statute. By 35 Eliz., c. 1, it is enacted, that if recusants, within three months after conviction, refuse or neglect to submit, they may, upon the requisition of four justices of the peace, be compelled to abjure and renounce the realm; and if they do not depart, or if they return without licence from the crown, they are guilty of felony, and to suffer death as felons without benefit of clergy.

The law recognised four classes of offenders under the statutes against recusancy:—those who absented themselves from the public service of the church from indifference, irreligion, or dissent, were termed 'recusants' simply—after conviction they were styled 'recusants convict;' those absentees who professed the Roman Catholic religion were called 'Popish recusants;' and those who had been convicted in a court of law of being Popish recusants were called 'Popish recusants convict.'

The laws against Popish recusants convict were of a very severe character. Montesquieu characterises them as so rigorous, that though not professedly of the sanguinary kind, they did all the hurt which possibly could be done in cold blood. The answer of Blackstone to this charge is rather a strange one, namely, that these laws were seldom executed to their utmost rigour, or, in other words, that they were enacted principally in terrorem. The truth appears to be that the first penal statutes passed for the purpose of compelling the adherents of the old religion to adopt the new, provoked resistance on their part; and this resistance caused severer enactments, producing in their turn increased resistance, followed by the imposition of still more rigorous penalties.

Popish recusants, in addition to the general penalties enacted against recusants, were disabled from taking lands either by descent or by purchase, after eighteen years of age, until they renounced their errors. They were bound at the age of twenty-one to register the estates which they had already acquired, and were bound also to register all future conveyances and wills relating to them. They were and are [QUARE IMPEDIT] incapable of presenting to an advowson, and of making a grant of the right of presenting at any avoidance of the benefice. They could not keep or teach any school, on pain of perpetual imprisonment. For the offence of saying mass, the Popish recusant forfeited 200 marks, or 133*l*. 6*s*. 8*d*. For the offence of wilfully hearing mass, he forfeited 100 marks (66*l*. 13*s*. 4*d*.), and was in each case subjected to a year's imprisonment.

Popish recusants convict incurred additional disabilities, penalties, and forfeitures. They were considered as persons excommunicated: they could not hold any public office or employment; they were not allowed to keep arms in their houses; they were prohibited from coming within ten miles of London, under the penalty of 100*l*.; they could bring no action at law or suit in equity; they were not permitted to come to court, under pain of 100*l*., or to travel above five miles from home except by licence, upon pain of forfeiting all their goods. Severe penalties were imposed in respect of the marriage or burial of the Popish recusant convict, or the baptism of his child, if the ceremony were performed by any other than by a minister of the Church of England. Such a recusant, if a married woman, forfeited two-thirds of her dower or jointure, was disabled from being executrix or administratrix of her husband, and from having any part of his goods, and she might be kept in prison, unless her husband redeemed her at the rate of 10*l.* per month, or by the profits of the third part of all his lands.

Protestant dissenters were relieved from the penalties of recusancy at the Revolution, by the Toleration Act, 1 William & Mary, c. 18. This statute contained a proviso (s. 17) that nothing therein contained should extend to give any ease, benefit, or advantage to any Papist or Popish recusant, or to any person that should in his preaching or writing deny the doctrine of the Trinity. But in 1791, by 31 Geo. III., c. 32, Roman Catholics taking a certain oath therein presented (altered in 1829, by the Catholic Relief Act, 10 George IV., c. 7) were exempted from prosecution, for being Papists and for not resorting to church; and in 1813, by 53 George III., c. 160, the exemption in the Toleration Act, as to persons denying the doctrine of the Trinity, was repealed. The statutes against recusancy, though seldom enforced, are still subsisting with respect to persons who, not being Roman Catholics or Protestant dissenters, absent themselves from the service of the Established Church.

RED. [CALICO PRINTING; DYEING; ENAMEL.; PAINTING, HOUSE.]

RED-BREAST. [SYLVIADÆ.]

RED DEER. [DEER, vol. viii., p. 358.]

RED LEAD. [LEAD, p. 370.]

RED MARL. An argillaceous red portion of the series of rocks between the coal and lias is thus termed in geology. Almost identical marls, similarly associated with red sandstones lie also in the upper part of the coal, and below the coal and mountain limestone. Nor would it be always easy to distinguish in specimens or even in sections on a large scale the upper red marls immediately below the lias of the Trent or the Avon from the red marls above the non-magnesian limestone of Knottingley, those above the magnesian limestone of Pontefract, those below the same limestone near Wetherby, those in the upper part of the coal formation of Manchester, or below the whole of the coal and mountain limestone in Monmouthshire. The phenomena attending the red colour in these deposits are entirely similar to those mentioned under RED SANDSTONE.

RED RIVER. [MISSISSIPPI, River.]

RED SANDSTONE. In geology this term is used in a variety of senses, partly with reference to the mere colour of certain rocks, and partly as expressing rocks of certain geological periods. Thus we have in the latter sense new red sandstone, lower red sandstone, and old red sandstone; and on the Continent, alter rother sandstein, neuer rother sandstein, le vieux gres rouge, le nouveau gres rouge, &c. The red sandstone also means, in some geological works, either the upper part or the whole system of the rocks, calcareous, argillaceous, and arenaceous, which occurs in the series of strata between the coal formation and the lias. If we regard the analogy of the geological nomenclature most generally used, this latter sense will appear too inconvenient to be adopted. as substitutes we have the Pœcilitic system, from the various colours of the component masses; and the Saliferous system, from its frequently containing salt. Under SALIFEROUS SYSTEM and in the article GEOLOGY will be found some general views. Our intention at present is to speak of red sandstones as mineral aggregates and as single terms which occur in several parts of the great series of stratified deposits.

Sandstones or gritstones, generally speaking, consist of abraded and worn pieces of quartz, felspar, mica, and other minerals, such as commonly occur in granite, gneiss, or mica schist, and other rocks associated with these. The size of these pieces is sometimes such as cause the mass to deserve the title of conglomerate (as part of the millstone-grit of Derbyshire), and sometimes the grains are so fine and confluent, that the mass is not unlike some sorts of quartz rock (as the ganister of the Yorkshire coal field). In regard to induration, there is every degree from uncoherent sand, through friable and argillaceous sandstones, to compact grits and indurated quartzose rocks. In colours they admit of every shade from whiteness, through grey tints by carbonaceous admixture, through yellow and brown hues by admixture of carbonate and oxide of iron, and through reds, blues, and purples of different kinds by diffusion of oxide of iron, manganese, &c.

In this most complex series of detrital deposits, red sandstones present some remarkable characters when regarded as to the *nature* and *diffusion* of red colour, the *association* of this with other tints, the *relation* of their hues to organic life, and to other geological phenomena.

Red sandstones occur in the basin of the Allier in France, in tertiary strata; in the plastic clay group of the Isle of Wight; generally in the strata below the lias and above the coal; in the upper parts of the coal formation of Derbyshire and Lancashire; in the millstone-grit series of Lancashire; in the mountain limestone of the north of England; generally in the strata called old red sandstone, above the strata of the Silurian districts; in the midst of the green and purple slates of north and south Devon; in the midst of older rocks in the Lammermuir, Cavan, and Longmynd ridges; but the most perfect and abundant types are in those parts of the series which lie above and below the carboniferous rocks, and constitute the new and old red sandstone groups.

The essential peculiarity of these reddened rocks is apparently a general diffusion in their mass, and especially round their constituent grains of quartz, of red peroxide of iron (with also often some oxide of manganese?). If by means of muriatic acid the iron be removed from the red sandstone of Manchester, what remains is a mass of mostly white and even translucent quartz grains, which had been invested by the red oxide of iron. Singularly enough, amidst a great series of such red sandstones and red clays, nothing is more common and even characteristic than to find oval, round, or irregular patches of light green colours, apparently due to the protoxide of the same metal. Nor is it at all rare to find perfectly white bands alternating with red or green stripes; and this applies almost equally to the sandstones, clays, gypsum bands, and salt layers.

A very remarkable and general fact observed in studying these red rocks is the paucity of the remains of animals of every grade. The new and old red sandstones of England were once believed to contain no such remains; a mistake certainly, yet founded on an important truth, which is even illustrated by the exceptions. Perhaps a more striking proof of the reality of the inverse relation here indicated, is given in the fossiliferous districts of north and south Devon, where the slaty rocks often do contain, and in particular layers abundantly, remains of zoophyta, conchifera, crustacea; but the bands of red sandstones, hard or soft, massive or laminated, argillaceous or gritty, appear almost utterly devoid of these reliquiæ. Thus in North Devon we have the following series of phenomena in a descending order:—

Blue, green, &c. slates of Ilfracombe	Partially fossiliferous.
Red sandstones of Martinhoe .	No fossils.
Green, grey, &c. slates of Linton	Very fossiliferous.

And in South Devon—

Blue and grey slates of Bovisand .	Fossiliferous.
Red sandstones of Staddon . .	No fossils.
Blue and grey slates and limestone of Plymouth	Fossiliferous.

(See De la Beche, *Report on Geology of Cornwall, Devon, and West Somerset.*)

The explanation which seems most probable is that water in which by any cause abundance of peroxide of iron has been diffused, is rendered thereby unsuitable for the due performance of the vital functions of aquatic creatures, especially such as take the water into their bodies for respiration, or are nourished by the flowing of currents to the mouth. We have been informed that experiments lately made by Mr. De la Beche, by putting red oxide of iron into water in which branchiferous mollusca were living, have justified the inference, and it seems desirable that such should be prosecuted and extended.

The last point on which it seems here necessary to remark is the frequent concurrence of red sandstones and clays, fibrous and lamellar gypsum, fibrous and lamellar rock salt. Most of the rock salt, of Europe at least, is associated with red earthy deposits; but there are great exceptions, as at Salzburg and Wieliczka. This frequent concurrence will be found of great importance in reasoning on the physical agencies whereby the peculiarities of red sandstones were occasioned.

As building materials, few of the red sandstones are to be recommended, and even the white layers which accompany them are seldom of much value. The cathedrals of Carlisle and Chester, and the noble old churches of Coventry, offer a striking warning to the architect; though on the other hand, part of the antient wall of Penrith Castle, still standing and in good preservation, shows that even among these justly suspected strata, some portions, either by their freedom from salt, or some other cause, are to be excepted from censure.

RED SEA. This sea resembles in form those large inlets of the ocean which in the mountainous regions of Scotland are called friths and in Norway fiords. It is a portion of the Indian Ocean, with which it is connected by the Gulf of Aden and the strait of Bab-el-Mandeb. [BAB-EL-MANDEB.] It extends from this strait (12° 40′ N. lat.) in a north by west direction to 30° N. lat. It lies between 32° 20′ and 43° 30′ E. long.

The length of this immense inlet is little short of 1400 miles: but the width varies, though in the greatest part of it the variation is not considerable. From the strait of Babel-el-Mandeb, which is only sixteen miles wide, it gradually enlarges; and at the distance of 160 miles from the strait it is 180 miles across: this breadth may be considered as the average width from Ras Essah or the island of Camaran to Jiddah, a distance of nearly 500 miles. Off Jiddah it is not much more than 120 miles wide; and this width continues to Ras Mohammed, south of 28° N. lat., where the sea divides into two arms: this distance considerably exceeds 500 miles. Of the two arms, into which the Red Sea branches off at Ras Mohammed, the eastern is called Bahr-el-Akaba, and the western Bahr-el-Suez, or Kolsum. Between these two gulfs is the mountain-region of Mount Sinai or Jibbel Musa (Mount of Moses). The Bahr-el-Akaba branches off in a north-eastern direction, and extends more than 100 miles, with an average width of less than 15 miles. Near its entrance is the island of Tiran, which is 800 feet above the level of the sea, and between it and the continent are two straits, of which only the western, called the strait of Tiran, is navigable for large vessels. The entrance of the Bahr-el-Suez is called the Straits of Jubal or Jublah, and is about fifteen miles across. The gulf itself runs in a north by west direction to its extremity at the town of Suez, a distance exceeding 180 miles; its average width is twenty miles. The surface of the Red Sea amounts to nearly 180,000 miles, according to an estimate.

The Red Sea is of great depth. The shallowest part is the Gulf of Suez, which in the middle, towards the Straits of Jublah, is from 40 to 50 fathoms deep; farther north its depth decreases to 30 fathoms; and approaching the harbour of Suez, it shoals to 20 fathoms, and by degrees to 3 fathoms, which is the depth of the harbour itself. The Gulf of Akaba varies in its middle part between 100 and 200 fathoms. The main body of the sea is still deeper, and in most parts a bottom cannot be found at the depth of 100 fathoms; in some places it is 230 fathoms deep. Towards the southern extremity, south of 16° N. lat., it grows much shallower, the depth in general not exceeding 40 or 50 fathoms.

This depth of water would be favourable to navigation, as the sea generally shoals to soundings near the shores; but the navigation is rendered difficult by islands, banks, and the prevailing winds. Small rocky islands are tolerably numerous, especially along the eastern shores, but as they usually contain small harbours, they would be rather advantageous were it not for the adjacent reefs. The islands are generally isolated, except between 15° and 17° N. lat., where the group of the Farsan Islands occurs along the eastern shore, and on the western that of the Dhalak Islands, each of which consists of a larger island and a great number of smaller islands, between which there are numerous reefs. South of these groups there are some islands dispersed in the middle of the sea, as Jibbel Teer, the Zebayer Islands (Jezayer es Seba, or the Seven Islands), and others. Two of these islands are volcanic, and on Jibbel Teer there is an active volcano, 900 feet above the sea.

The Red Sea is the most northern portion of the ocean in which coral reefs occur, and they are more numerous than in any other part of the sea of equal extent. They differ in their form from those which are found in the Pacific Ocean, never having a round figure, but almost always extending in a tolerably straight line, and parallel to the coast; the interior is filled up, so that they never contain a lagoon, as is almost invariably the case with those in the Pacific. These coral-reefs are frequently united with the adjacent continents, and render the shores almost inaccessible, as the water near them is very deep, and the reefs themselves have only from 3 to 6 feet water, which gradually shoals on approaching the beach, so that even boats are stopped at the distance of a quarter of a mile from the dry land. The reefs which are unconnected with the shores are still more numerous, and frequently several miles from them. Their edges towards the open sea are very steep, and the sea itself is of great depth. But the edge which is opposite the mainland has usually a gradual and gentle slope, and affords good anchorage to vessels. The sea between this inner edge and the mainland is generally not very deep, and the small vessels of the country navigate these straits in preference to the open sea, as the water is less agitated by the winds, and they are always in the neighbourhood of some place which offers anchorage in case a gale should rise. The winds, which commonly are very strong in the open sea, can hardly be said to extend to these straits, so that small vessels can take advantage of the sea and land breezes, which regularly set in at certain hours of the day, at least during the greatest part of the year. These advantages however are lost by the necessity of putting into some harbour during the night. The isolated small coral-reefs, though numerous, are easily avoided in the day-time, the water of the sea being so clear that they can be distinguished at a great distance. In addition to this, vessels are obliged to follow the shores, which nearly doubles the length of their voyage. The reefs are much more numerous along the Arabian than on the African coast. South of the groups of the Dhalak and Farsan Islands only a few small ones occur on each shore. Both groups are surrounded with and intersected by reefs. North of the Dhalak Islands, as far as the entrance of the Bahr-el-Suez they are neither large nor numerous, except for several miles south of the harbour of Suakin (near 19° N. lat.), and between Ras Erba (Elba) (22° N. lat.) and Ras Bornas (24° N. lat.), where they are numerous and extensive. In the Strait of Jublah many small ones occur, and several are found in the Bahr-el-Suez. Hardly any reefs occur in the deep inlet called Bahr-el-Akaba, but reefs are numerous in the Straits of Tiran; in fact the eastern strait, which is formed by the island of Tiran, is quite locked up with them. From this point southward to the parallel of Jiddah (21° 30′ N. lat.) the coast is nearly blocked up with them, except between Ras Bareedy and the harbour of Yambo. Between Jiddah and 20° N. lat. the Arabian shores are remarkably free from reefs; but from that latitude to the Farsan Islands they are so numerous and large as to render the navigation extremely dangerous.

The reefs are more dangerous to the unwary navigator as a heavy surf is never observed on them, whatever may be the state of wind and weather. Lieutenant Wellsted thinks that the absence of surf may be accounted for by the porous nature of the coral which constitutes the outer part of the reefs, by which the force of the sea is broken in the same manner as that of a body of water would be broken, if dashed against a sieve.

The Red Sea occupies the lowest portion of a deep valley which lies between the elevated table-land of Arabia on the east, and the high lands of Abyssinia, Nubia, and Egypt on the west. The outer edge of these table-lands is generally from 10 to 30 miles from the shores, and has the appearance of a continuous mountain-range, varying in height between 3000 and 6000 feet. These mountains approach much nearer to the shores north of 24° N. lat. than south of that parallel. The space between them and the shores is partly occupied by hills, which skirt the edges of the table-land, and partly by a low and level tract along the sea, which is generally sandy, but sometimes swampy. This tract, as well as the hills between it and the mountains, is far from being sterile, and it has also the advantage of rains in November, December, and January; but it is nearly uncultivated, as the inhabitants, who consist of several tribes of Bedouin Arabs, are averse to industry, and make no other use of these tracts than as pasture-grounds when the grass on the table-land is dried up.

The peculiar position of the sea between two elevated table-lands has a great influence on the direction of the winds. During the warm season, from May to October, northern breezes prevail throughout the whole extent of the sea. They blow not without interruption, but frequently for several days with considerable force. During this period the reefs have about two feet less water on them than in the remaining months of the year, a circumstance which may be attributed to the continual current which at that time sets through the Straits of Bab-el-mandeb into the Gulf of Aden. In the winter, from October to May, northern winds are prevalent in the northern part of the sea; but in the southern, they blow from the south, and generally with great constancy. The currents then change, and flow back with great rapidity; and, as the whole body of water has no means of escaping, it is collected towards the northern parts of the sea, and becomes considerably elevated. As the winds always blow in the direction of the length of the sea, they affect only the open parts, and not the straits between the reefs and the mainland, in which, as already observed, a regular change of land and sea breezes prevails.

The principal harbours on the Arabian shores are Mokha, Hodeidah, and Jiddah; and on the African, Suez, Cosseir or Cosire, Suakin, and Massowah. There is a pretty active communication kept up between these places, especially by the numerous pilgrims who visit Mecca and Medina from the eastern countries of Africa. The country vessels bound from Cosire to Jiddah cross the sea to the nearest point of the opposite coast, and then sail along shore to Jiddah. Those from Jiddah to Cosire follow the coast as far north as Moilah, or Râs Mohammed, and cross from thence with the northerly winds. Ships bound from Suakin to Jiddah proceed along shore as far as Salakah (20° 30′ N. lat.), and thence stretch across the sea to Jiddah. When they are bound from Suakin to Mokha, they generally proceed southward along the African coast till they reach Massowah, whence they cross over to the Arabian shore. These vessels, perhaps exceeding four hundred in number, are of various descriptions, and most of them are between 50 and 200 tons burden. The greater number are employed in the transport of pilgrims, whose number annually exceeds 20,000; and of grain and slaves, which constitute nearly the whole of the exports from Africa to Arabia. As Arabia does not produce sufficient supplies for the pilgrims who visit Mecca, and annually amount to above 120,000 individuals, the transport of grain from Cosire to Jiddah employs a great number of vessels. The grain is procured from Upper Egypt; and after being collected in the granaries of Kenneh, is forwarded by camels to Cosire. This trade is now carried on entirely on account of the pasha of Egypt. Hardly any merchandise is brought from Suakin and Massowah to Arabia, except slaves.

As the countries along the shores of the Red Sea do not produce many articles of export, they are not much visited by foreign vessels. The few which navigate this sea go to Mokha and Jiddah. They come from the Persian Gulf, Hindustan, and the Indian Archipelago. The vessels from Basra and Abu-shehr import wheat, tobacco, dates from Basra and the Bahrein Islands, and Persian carpets, which are mostly purchased by the Bedouin sheikhs: they bring also some rich pilgrims from Persia. From Calcutta, and occasionally from Bombay, are brought rice, sugar, and Dacca muslins: also coarse and fine blue cloths, cambric, and indigo; with teak timber, palm-oil, cocoa-nuts, and the spices of the coast of Malabar. The vessels from the Indian Archipelago bring spices (especially those of Malabar), rice, and a number of young females, who are sold to the Turks at the price of 150 to 300 dollars. Besides this commerce, which is carried on in square-rigged vessels, a considerable number of large bagalos from Hindustan, especially from Mandaree in Kutch, bring to Arabia the produce of India. The returns for the foreign goods imported into Jiddah are generally cash, which is brought by the pilgrims, to whom nearly all the goods are sold; but coffee, Arabic gum, myrrh, and frankincense are exported from Mokha. The coffee grows on the hilly declivity of the table-land north of Mokha; but the other three articles are imported from Africa, where they are collected in the countries along the southern shores of the Gulf of Aden, and in the vicinity of Cape Guardafin.

The first mention of the Red Sea occurs in the Bible, on the occasion of the Israelites passing through it. Soon after that time, if not before, it seems to have been navigated. In the time of Solomon the advantages of such a navigation were well understood; for after the conquest of Idumæa by David, and the acquisition of the country near the Bahr el Akaba, Solomon established at Elath and Ezion Geber, on the shores of that gulf, a colony of Phœnician navigators. It is however uncertain if the navigation then extended to India. According to the authority of several Greek authors, the most antient intercourse between India and the countries on the Mediterranean was carried on by means of the Persian Gulf. Modern writers have had some doubt of this fact, on account of the difficulty of transporting the goods through that extensive desert which intervenes between El Katif, the supposed emporium on the Persian Gulf, and the Mediterranean. But this doubt has been removed, since it has been discovered, in the course of the wars of the pasha of Egypt with the Wehabites, that a series of extensive oases stretch across the Arabian peninsula between 24° and 26° N. lat.; and that through the western of these oases the road passes by which the haji, or caravan of pilgrims, passes from Damascus to Medina. This route seems to have been the most frequented up to the time of Alexander. It is however probable that before his time some connection existed between the Red Sea and India, though it was not the most common channel by which the exports of India reached the Mediterranean. But when the wars subsequent to the death of Alexander rendered the transport of commodities through Syria dangerous, and the policy of the kings of Egypt favoured the navigation and commerce of the Red Sea, it became soon the principal channel of commerce between Europe and India. This intercourse continually increased, though slowly, as the exports of India at that time consisted only of articles which were consumed by the rich. But in the first century of the Christian æra the trade was so considerable, that, according to Strabo, 120 vessels annually departed from Myos Hormos to India. The true situation of that harbour is not known, but it is supposed to be near 25° N. lat. The conquest of Egypt by the Arabian khalifs, in the seventh century, does not seem to have diminished the intercourse between the two countries, as it is certain that in the ninth century the Arabs extended their navigation from the Red Sea through the Indian Ocean to Canton in China. Soon after that time the Venetians established factories in Alexandria; and the goods of India passed by the Red Sea to that town, and thence to Europe, during the period between the twelfth and fifteenth centuries, until the discovery of the route round the Cape of Good Hope directed the whole commerce of India into a different channel. The commerce and navigation of the Red Sea were nearly annihilated by this event, and recovered only a little in the seventeenth century, owing to the cultivation of coffee in the southern districts of Arabia. It has recently somewhat increased, mainly in consequence of the tranquil condition of Egypt under Mohammed Ali and his authority among the Bedouin tribes which inhabit the Arabian coast. In addition to this, steam-boats from India have recently navigated the sea as far north as Suez, and thus a much shorter communication between Europe and India has been established. But the progress of the steam-boats is slow, on account of the heavy gales which blow, with short intermissions, in the northern part of the sea. It has therefore been proposed to employ only small steam-vessels, so that when impeded in their course by these gales, they may, like the Arabian vessels, sail in the narrow straits between the Arabian coast and the reefs. We do not know if this plan has been adopted.

The name Red Sea is a translation of the Latin Rubrum Mare, and the Greek term (Ἐρυθρὰ θάλασσα) used by Strabo. Herodotus calls the Red Sea the Arabian Gulf, and also includes it in the general term of Erythræan Sea, which comprises the Indian Ocean and the Persian Gulf.

(Lord Valentia's *Voyages and Travels to India, Ceylon, the Red Sea, &c.*; Burckhardt's *Travels in Nubia*; Rüppel's *Reise in Abyssinia*; Wellsted's *Observation on the Coast of Arabia, &c.*, and *Notice of the Ruins of Berenice*, in 'London Geog. Journal,' vol. vi.; Burnes and Dickinson, *On the Maritime Communication of India*, in 'London Geog. Journal,' vol. vi.; Ehrenberg, *Ueber die Natur und Bildung der Coralleninseln, &c. im Rothen Meere*; *Chart of the Red Sea, according to the Survey of Elven, Pinching, and Moresby*, by Carless.)

REDAN is the simplest kind of work employed in field fortification, and it consists generally of a parapet of earth, divided on the plan into two faces, which make with one another a salient angle, or one whose vertex is towards the enemy. Existing alone, the work is capable of making but a feeble defence, since its faces are not defended by any flanking fire; and, being open at the gorge or rear, the enemy may easily enter it in that direction. It can therefore be of use only at an outpost, to afford a momentary cover for troops who are to retire when a superior force advances against them. A redan may however be advantageously placed to cover the head of a bridge, the entrance into a village, or defend the ground in front of some strong redoubt; a series of them may also be constructed along the front of an army, in order to strengthen the position and cover the artillery; and, in all these situations, the defects above mentioned cease to exist, since in the first case the gorge is protected by the river, and in the others the faces and gorges are defended by the works or by the troops in the rear.

When it is required to defend any pass immediately on the right or left of redans, flanks, making salient angles with the faces at points near the extremities of the latter, are given to them, so that they then become what are also called bastions or lunettes; and the necessity of having a crossing fire for the defence of the ground in front, when the redans are not flanked by other works, has at times induced engineers to break the lines of parapet near the gorges, so as to form re-entering bends, and thus constitute a wing on each side at a right angle with the face.

Among the works constructed, in 1810, for the defence of Lisbon, redans were frequently placed on projecting knolls, in front of the great redoubts, in order to flank the ground which was unseen from the latter: their gorges were protected by palisades, or by parapets, sufficiently slender to have been demolished by the artillery of the principal work, had the enemy succeeded in capturing them; and good communications, covered by the inequalities of the ground, or by earth purposely thrown up, were formed in order to allow the defenders, if necessary, to retire in security. The strong stone windmills, which in that country are often built on salient knolls of ground, were occasionally covered by redans of earth; and thus were formed good defensive posts, to each of which the mill served as a reduit or keep. During the struggle in the south of France, in 1813, Marshal Soult caused redans to be constructed as outworks, one below another, on the descending tongues of land which project from the main chains of heights whose summits he had crowned by strong redoubts.

Two redans connected together, so as to leave one re-entering angle in front, form a queue d'hyronde; and the name of bonnet de prêtre has been sometimes applied to a work consisting of three redans so placed.

REDEMPTION. [Atonement.]

REDEMPTION, EQUITY OF. [Mortgage.]

REDI, FRANCESCO, born at Arezzo in 1626, studied at Florence and Pisa, and took his degree of M.D. in the last-named university. He afterwards proceeded to Rome and Naples, where he applied himself to the study of natural history, and made several curious physiological experiments. On his return to Tuscany, he practised medicine with great reputation, and wrote several works concerning that science. Redi was also a poet, and wrote a dithyramb, 'Bacco in Toscana,' in which he extols the various produce of the Tuscan vineyards: it is a splendid specimen of that species of composition. His other works are:—1, 'Esperienze intorno alla Generazione degli Insetti,' Florence. 1668; 2, 'Osservazioni intorno alle Vipere,' 1664; 3, 'Esperienze intorno a diverse Cose Naturali, particolarmente a quelle che ci sono portate dall' Indie,' 1671, 4to.; 'Osservazioni intorno agli Animali viventi che si trovano negli Animali viventi,' 1684; 5, 'Lettera intorno all' Invenzione degli Occhioli,' 1678: 6, 'Consulti Medici,' 1726-9. 7, 'Lettere Familiari,' 1724-7; 8, 'Sonetti' and other poetry. There are some other of his minor works inserted in the general collection, 'Opere di Francesco Redi,' 3 vols. 4to., Venice, 1712. Redi was a most correct and elegant Italian writer, and also one of the most learned men of his age and country. He was a great favourite with the court of Tuscany, and was physician to the grand-duke Ferdinand II. Redi died at Pisa, in 1698.

RE'DON. [Ille et Vilaine.]

REDONDA. [Montserrat.]

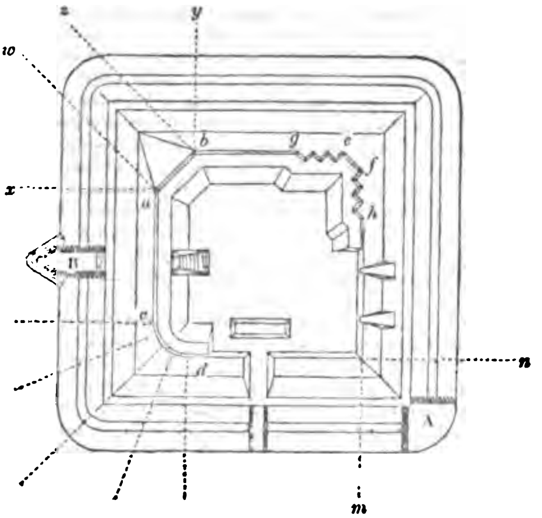
REDOUBT is a general name for nearly every kind of work in the class of field fortifications; thus a redan with flanks, a parapet enclosing a square or polygonal area, a work in the form of a star [Star-fort], and a fort with bastions at the angles, like the enceinte of a fortress, are occasionally so called; but the second of these is the work to which the term is more particularly applied, and it is that which we purpose now to describe.

When a work to be constructed on level ground is intended to contain troops and artillery for the purpose of preventing the enemy from occupying the spot, and when there is an equal probability that the work may be attacked on any side, that spot should be quite enclosed by the parapet; also if the defence is to continue only till succour can arrive from the army in the vicinity, flanking defences being then scarcely necessary, a quadrangular figure may suffice for the plan of the work, and there can be no reason why one side should be longer than another, or why the sides should form with each other any but right angles. But when the redoubt is to occupy an eminence whose figure on the plan is irregular, the faces of the work, whatever be the form thus produced, must necessarily be traced so as to correspond to the different directions assumed by the brow of the height; and if the fire of the work is intended to defend some fixed object, as a pass leading towards it, one of the faces must be perpendicular to the direction of that pass. It may be observed however that in general the number of faces, though not less than four, should be as few as possible. The ditches of all polygonal works without re-entering angles, are incapable of being defended by the fire from the parapets above, on account of the height and thickness of the latter, which prevent the soldiers from seeing them; and a curvilinear redoubt has, besides, two defects which are irremediable; the fires from its parapets are diverging, therefore they produce little effect while the enemy is advancing up to the work; and the ditch, on account of its form, is incapable of being defended from stockades within it. These objections apply with nearly equal force to redoubts formed on regular polygons of more than five or six sides. The French however made a circular redoubt of casks for the purpose of strengthening the defence of the isthmus at St. Sebastian previously to the siege of that place in 1813; and circular redoubts of masonry are supposed to be useful on the sea-coasts. In the latter situation they are not liable to be attacked by infantry; and their artillery, which is mounted on traversing platforms, may be fired in any direction against ships or boats, should an enemy attempt a debarkation of troops. [Martello Towers.]

Every work in field as well as in permanent fortification is surrounded by a ditch, from whence is obtained the earth for the parapet, and by which the difficulty of carrying it by assault is increased. The ditch is generally crossed directly opposite the entrance by a bridge of timber, which should be capable of being drawn into the work, or re-placed at pleasure. The entrance into a redoubt is at a re-entering angle, if there is one, otherwise it may be about the middle of one of the faces on the side which is least exposed to the view of the enemy; and, besides being barricaded, it is defended by the fire from a traverse, which is raised in the interior, and perpendicular to the direction of the passage.

Redoubts for the defence of positions are in general intended to contain only about fifty men with three guns; but works in the form of irregular polygons have sometimes been constructed of a magnitude sufficient to contain 1600 men and twenty-five pieces of artillery; and such were the two principal redoubts (on Mount Agraça and at Torres Vedras), formed in 1810, in order to protect Lisbon. These were expected to make a vigorous defence in the event of being attacked; but it is admitted that their *trace*, or ground-plan, was defective on account of the want of flanks, and perhaps they would have been prevented from falling only by the strong divisions of troops who were daily under arms in their vicinity. The redoubt constructed by the British in the neighbourhood of Toulon, in 1793, for the protection of the town and fleet, was a large work well furnished with artillery; yet, on being attacked by the republican troops, it was taken, after a gallant resistance, in which the enemy was twice repulsed. The ditches being undefended by flanks, the assailants, on being driven into them, re-formed their order with little molestation; and at the third attack they succeeded in getting possession of the work.

It is admitted among military men that in firing over a parapet, the soldier doing the duty as rapidly as possible, and fearing to expose himself while adjusting his musket, places the latter mechanically in a direction nearly perpendicular to the line of the face behind which he is stationed. It follows that in front of every salient angle of the work there must be an undefended sectoral space, as *mn*, in the subjoined cut, which represents the plan of a square redoubt, in which space, in order to avoid the direct fire from the faces, the enemy may advance to the attack; and on this account it is recommended that the faces of the work should be disposed so that the angles may be turned towards ground which is impassable, or which will not permit the enemy to establish batteries for the purpose of enfilading those faces. When this disposition is not possible, various methods may be adopted by which the troops who man the work might direct some of their fire within those sectors. The simplest of these, and that which is generally put in practice, is to form the crest of the parapet near the angles perpendicularly to the *capital* (the line bisecting the angle) as at *ab*; by which means the space between *w* and *z* may be directly defended, and the sectors *xw* and *zy* being small,



very little attention on the part of the men about *a* and *b* will enable them to give their muskets an oblique direction so as to fire upon an enemy advancing within those spaces. A second method is that of rounding off the interior of the parapet at the angles, as at *cd*; but this has been objected to on account of the divergency of the lines of fire. The third method, which is much dwelt on by writers on fortification, consists in forming the interior of the parapet with indentations, as at *eg* and *fh*, alternately parallel and perpendicular to the capital, each indent being three feet long; and a parapet of this kind is said to be *en cremaillère*. It is evident that by placing men contiguously to the sides of these indentations, a fire may be kept up in either of the directions just mentioned; and by placing them at the angles, they may fire perpendicularly to the general face of the work. It must be observed however that the men cannot fire in these different directions at the same time, because, the muskets crossing one another, that of one man might be injured by the fire of the next. The only objections to this method are, that the parapet can be so formed only by men belonging to the corps of sappers and miners, who are regularly trained to the construction of fortifications, but who may not be present when wanted; and that the unsteadiness of the soldiers in firing almost always renders such precision in the formation of the work useless.

The ditch of a redoubt having no flanks, being unseen and incapable of defence from the parapets, it has been proposed, in order to have some means of annoying the enemy when in the ditch, to form an enclosed space A, at one or more of the angles of the ditch, by planting a line of palisades across the latter on two contiguous faces of the work; the enclosure may have a roof of timber covered with earth, and loop-holes, three feet asunder, must be cut in the palisades, that the defenders may be enabled to fire along the ditches.

Another method, which may be advantageously adopted when a face of the work has considerable length, is to form, as at B, what is called a palisade caponnière, by planting across the ditch, at the middle of the face, two rows of palisades about eight feet asunder; each row being pierced with loop-holes. The entrance into the caponniere is by steps in the interior of the redoubt and a gallery under its parapet; and this work, as well as that at A, may have a roof, but in no case should such roof be above the level of the natural ground, in order that it may be concealed as long as possible from the view of the enemy. One of the redoubts which was executed near Lisbon, being commanded by a height in its front, from whence the parapets might have been destroyed and the interior ploughed by shot, there was formed a gallery behind the counterscarp, and opposite one of the angles of the work, with loop-holes, from whence the ditch along each face might have been defended by musketry if the enemy had penetrated into it. The soil being chalk, no timber-frames were necessary for the support of the sides or top; and between this recess and the interior of the redoubt there was a gallery of communication passing under the bottom of the ditch.

A row of palisades is frequently planted quite along the ditch of a redoubt. Sometimes also the escarp of the work is fraized, or furnished with palisades planted in an inclined position, and a line of chevaux-de-frize is disposed upon the berme. In order to retard the advance of an enemy, the work is generally surrounded, at a distance not exceeding the range of musket-shot, by a single or double abatis, and often by two rows of pits called *trous de loup*.

The magnitude of a redoubt, whatever be its form, is determined by the strength of the garrison and the quantity of ordnance by which it is to be defended; all the men being supposed to be lodged within it. It was formerly the practice to allow on the area of the terreplein, within the foot of the banquette, ten square feet for each man, and 324 square feet for each piece of artillery; consequently when the redoubt is of a square form, the breadth of the banquette being known (about 11 feet), the length of the crest-line on each face could be easily determined. In order that the defenders may conveniently use their arms on the banquette, it has been customary to allow three feet along the crest of the parapet for each man, who is to stand contiguously to the interior slope; and it was once considered that a redoubt intended to make a considerable resistance when attacked on all sides, would be adequately garrisoned if the number of men in it were equal to the number of feet in the whole length of the crest of the parapet; that is to say, if there were three ranks of men along each face, the work being supposed to be capable of containing such a number. It is said that each side of the square redoubts which Marshal Saxe caused to be constructed at the siege of Maestricht in 1748 was above 100 feet long, measured on the crest of the parapet, and that each redoubt was garrisoned by 500 men; and it will be found by computation that, consistently with the above rules, a square redoubt, each of whose faces is sixteen yards long, is the least that ought to be constructed; for if less, the interior within the banquette would not contain the number of men necessary to line its parapet with one rank. But the rule relating to the area within the banquette has been objected to as an unnecessary affectation of mathematical precision. The British engineers who constructed the works for the protection of Lisbon observe that, except at night, or at the moment of being attacked, part of the garrison will be on watch, or otherwise occupied outside of the work; and even at those times, at least one-third will be under arms on the banquette. Colonel Sir John Jones states that the strengths of the garrison were finally determined by allowing two men per yard in the length of the parapet for the exterior works, and one man per yard for the interior works; deductions being made for the spaces where artillery was to stand. Each gun takes up about eighteen feet of the length of a parapet.

The crest of the parapet of a redoubt may be about 8 feet above the natural ground, unless the work is to be defiladed from some commanding ground in the neighbourhood, in which case it must be higher. The form of a section or profile of the parapet is similar to that which is used for permanent fortification [Lines of Intrenchment, *fig.* 4], but the breadth of the superior slope may vary with the nature of the arm which the enemy can bring against it; three feet will suffice if the work can be attacked by infantry only, but it may be as much as 10 or 12 feet if it is to resist field artillery of the heaviest calibre. The superior surface of the parapet should slope down towards the exterior, so that the defenders may see the top of the counterscarp of the ditch in front; and when, from the great relief of the work, this is impossible, the counterscarp should be raised by earth obtained from the ditch to the height necessary for this purpose; taking care however to give the raised earth a gentle slope towards the exterior, that the enemy may not be screened by it. The exterior of the parapet and the escarp of the ditch are covered or reveted with sods when the earth has not sufficient tenacity to stand unsupported; and when the work is to resist the fire of heavy artillery, the revetment might consist of stout logs of timber planted obliquely in the ground or in the bottom of the ditch, and leaning against the face of the work. The interior of the parapet is usually reveted with sods or fascines.

Redoubts are intended to fortify military positions, for which purpose they usually occupy the heights and command the defiles; and their magnitude or number must depend upon the time afforded for their construction. [LINES OF INTRENCHMENT; MILITARY POSITIONS.] It sometimes happens that they are thrown up during a night to protect artillery on the wings, or in some important situation in front of the army, in expectation of an engagement taking place the next day; and then they are necessarily few and small. When Marshal Soult was reduced to defensive operations in the south of France, in 1813 and 1814, he strongly entrenched the heights on all the frontier between the sea about Bayonne and St. Jean-de-Luz, and the mountains at St. Jean-Pied-de-Port; an extent of above 16 miles. The works, which were executed in three months, were generally irregular polygons; and some of them were constructed for 500 men. More than a year was spent in raising the redoubts which covered Lisbon; and consequently these were not only strong, but numerous beyond any other example. [ENCAMPMENT.] They were of every trace, but mostly irregular polygons, whose sides sometimes formed re-entering angles, as the ground required: the two great redoubts before mentioned were retrenched by interior parapets, which also served as traverses, and each salient point of the redoubt at Torres Vedras constituted an independent post.

Attack and Defence of a Redoubt.—In the attack of a small redoubt unprovided with artillery, light infantry or riflemen, keeping for a time as much as possible covered by the inequalities of the ground, endeavour to surround the work, and, by a fire of musketry, directed towards the crest of the parapet, to diminish that of the defenders. The assailing troops then gradually close in upon the redoubt, and, while one division remains on the counterscarp to continue the fire, should the defenders show themselves upon the parapets, the rest descend into the ditch, where, having collected themselves in parties or small columns, they mount the parapet on each side of a salient angle; then developing themselves on the summit, they make a general discharge and enter the work. In order to avoid accidents in descending into the ditch, or in ascending the escarp, it is recommended that the bayonets should not be fixed by the assailants till they have gained the berme of the work.

But if the redoubt is of considerable magnitude, if it is furnished with artillery, and moreover protected by palisades in the ditches, and abatis or other obstacles in the front, the attack must be conducted with more powerful means. It should commence by a fire of artillery directed partly so as to enfilade the parapets, break down the palisades and derange the abatis, and partly to destroy the merlons which cover the artillery of the work. The fire of the latter being thus in some measure silenced, the light infantry, as in the former case, endeavour by musketry to prevent the defenders from manning the parapets; and in the mean time columns of troops advance towards the angles, being preceded by parties of sappers and miners, who make openings for them in the line of abatis, or cover with timbers the trous de loup, if such there be. If the ditch is deep, the descent into it, and the subsequent ascent of the escarp, must be facilitated either by placing scaling-ladders or by throwing in fascines or bags of hay; and any palisades or other obstacles which may not have been displaced by the artillery, must now be cleared away by the working-parties which accompany the troops. The fire of the covering parties must cease while the assailants are mounting the parapet, but it must recommence if they should be repelled: in the latter case the storming troops reform their order in the ditch, and again attempt to enter the work. It may be supposed that at length they will succeed, when the defenders, if not provided with a redoubt to which they may retire for the purpose of capitulating, must surrender at discretion. In 1793 the French camp under Valenciennes was protected by works which, though furnished with artillery, were open at the gorge; and in an attack, the British cavalry, having entered those works at their rear, made prisoners of all the defenders.

When a redoubt is threatened with an attack, the officer commanding it endeavours to provide against the event by disposing in front of the work all possible obstacles to the advance of the enemy, and by placing sand-bags on the parapets in order to cover the defenders, who are to fire through small intervals left for the purpose: these measures should be taken, if not before, during the night preceding the attack; since the latter generally takes place early in the morning. On the advance of the assailants, the artillery of the work is made to play upon their columns; and the fire of musketry commences as soon as the latter are within the proper range. These fires are kept up vigorously while the assailants are clearing away the obstacles, and until they have descended into the ditch. Should the work have flanks, and the guns behind them be not dismounted, a fire of grape-shot and of musketry must now be directed along the ditches; while hand-grenades and stones are thrown, and live shells are rolled into them from the parapets of the faces. The storming troops may however persevere, and may at length mount upon the parapet, in which case they must be received by a fire of musketry from the defenders on the terreplein; and the latter, if overpowered, must endeavour to retire or capitulate.

Any works constructed within others, in order to prolong their defence, or to afford a retreat for the troops who occupy them, are also called redoubts; but by the French engineers, reduits or retrenchments. [RETRENCHMENT; BLOCKHOUSE.]

REDRUTH, an unincorporated market-town in the hundred of Penwith, in the county of Cornwall, 268 miles from the General Post-office, London, by the Southampton railroad to the Andover-road station (55 miles), and from thence by Andover, Salisbury, Dorchester, Bridport, Exeter, Launceston, Bodmin, and Truro. It is supposed to be a very old town; the original name was Dredruith, interpreted to mean Druids' town; but it did not possess any importance till modern times, when its copper-mines have given it wealth and population.

The area of the parish is 3770 acres. The population, in 1831, was 8191. The town stands on the brow of a hill, and consists for the most part of one long street, running northeast and south-west, indifferently paved, and lighted with gas. The church, dedicated to St. Uny, is about half a mile south-west of the town; it was rebuilt A.D. 1770. There are the remains of an antient chapel in the town, and there are meeting-houses for Baptists, Quakers, and Primitive and Wesleyan Methodists. There are a market-house, shambles, a small theatre, and a spacious handsome savings' bank, which, there being no town-hall, is used upon the revision of lists of county voters and for other public purposes. Near the entrance to the market-place is a clock-tower with an illuminated clock.

The wealth of the town is derived from the valuable tin and copper mines in this and the adjacent parishes. There are weekly sales of copper-ore, and stores of such articles as the miners require are kept in the town. There are two weekly markets; the Friday market is a considerable corn-market; there are three yearly fairs, chiefly for cattle.

The living is a rectory, in the archdeaconry of Cornwall and diocese of Exeter, of the clear yearly value of [illegible], with a glebe-house. There were, in 1833, one infant-school, with 154 children of both sexes; seventeen day-schools, with 372 male and 190 female scholars; and three Sunday schools, with 394 male and 301 female scholars. There is a subscription reading-room.

There are several villages in the parish; at one of them, called Plaingwary (that is, in Cornish, plân an guare, the plain of sport or pastime), are the remains of one of the 'rounds' in which plays were antiently performed. These rounds are described in the article CORNWALL [vol. viii, p. 38].

The Redruth and Chasewater (or, as it is more commonly called, Redruth and Deveron) railway extends from Redruth to Deveron, a shipping-place, on a creek running up from Falmouth harbour. It traverses the great mining parish of Gwennap, and communicates by branches with other mining districts, and also with Portreath, a seaport on the North Channel. The carriages are drawn by horses, at a rate of three or four miles per hour. This railway is used chiefly for the conveyance of ores from the mines to the places of shipment; coals, timber, &c. from the wharfs to the mines; and flour and merchandise to Redruth and the intervening villages. By means of a short branch it joins the railway from Redruth to Hayle, the waggons or carriages being loaded and unloaded from one railway to the other. The length of the main line is about fourteen miles. This railway, which was formed under an Act passed in 1824, has been open about fifteen years, and has proved very profitable.

The Hayle railway, which was also constructed by a joint-stock company, under Acts obtained in 1834 and 1836, affords communication by its main line between the town of Redruth, the adjacent mines, and the port of Hayle, its extreme length being about twelve miles. It has several branches, the principal of which is about three miles and a half in extent, and communicates with the seaport of Portreath. The line is worked by locomotive and stationary steam-engines, at a speed of from twelve to twenty miles an hour, the latter being used in some parts on account of the steepness of the inclined planes. The traffic is of much the same description as that on the Redruth and Deveron railway, and a large quantity of general merchandise is conveyed inland, which is brought by a steamer that plies between the ports of Hayle and Bristol. This railway (on which no passengers are conveyed) has been open about three years, but has not hitherto realised the expectations of its projectors.

REDSTART. [SYLVIADÆ.]

REDU'CTIO AD ABSURDUM. [ABSURDUM, REDUCTIO AD.]

REDUCTION. This term is used in arithmetic in the well-known sense of the operation of turning one denomination of weights or measures into another; thus shillings may be reduced to pounds, or pounds to shillings. It is also used in the same sense throughout analysis, namely, that of bringing one form into another, making one question depend upon another, &c.; in fact, for transformation generally. It were to be wished that the latter word transformation should take its place whenever the two forms are of equal difficulty or the two questions of the same character, &c., and that reduction should be employed only when there is really a reduction, that is, a bringing down either of dimension or difficulty, &c. Many writers do use the word thus, and thus only, but others do not.

REDUCTION INTO POSSESSION. [POSSESSION.]

REEFS, or CORAL REEFS, are a peculiar kind of rock which occurs abundantly in some parts of the ocean. They differ from other rocks in extending over a considerable space of the sea in length, with a very narrow width. Generally they are also only a few feet below water; so that on the side where they are washed by the open sea, a heavy surf is continually running against them.

Reefs appear under various forms. In some places they are contiguous to the shores, as in the Red Sea; in others they fringe the shores, being separated from them by a narrow channel of moderate depth. Sometimes they surround islands at a considerable distance from the shores, and the islands so encircled are almost without exception of volcanic origin. Very frequently they surround a portion of the sea, within which there are some small islands, which are often contiguous to the reefs, and seem to be a part of them, as both are composed of the same material. There are also coral reefs at a great distance from the land, which run nearly parallel to it, like a barrier. Among the latter are those of the Coral Sea, along the eastern coast of Australia. [PACIFIC.]

The attention of navigators and naturalists was first attracted to those islands which go under the name of Lagoon Islands. A reef approaching in form to a circle surrounds a part of the sea and forms a lagoon, on the inner part of which there are usually several smaller islands, wooded and inhabited, which are contiguous to the reefs themselves, and frequently extend along them with little interruption. The water on the outside is always nearly unfathomable, but within the reefs good anchorage is generally found, and the reefs themselves have one or more openings of deep water, by which the largest vessels may enter the lagoon. Accurate observers soon discovered that the reefs were composed of coral, and were the production of an animal. On these circumstances the first theory of reefs was founded. This theory received some addition from Forster, who accompanied Captain Cook on his second voyage. According to him, they are raised by these small animals perpendicularly like a wall, from a great depth to a very small distance from the surface of the sea. The waves afterwards bring sand, muscles, tang, and pieces of coral, and deposit them on the reef, which, in this way, is gradually raised above the sea-level, and becomes fit for vegetation. Currents and sea-fowls bring the seeds of marine plants, which, being decomposed, form a mould on which the cocoa-nut palm, when carried thither by the waves, thrives luxuriantly. This theory of Forster was adopted and extended by Flinders, who in surveying the coasts of Australia had abundant opportunities of observing the formation of these islands; and still more by Peron and Chamisso. The last-mentioned naturalist accompanied Kotzebue on his first voyage of discovery (1815-1818).

But facts have since been observed by Quoy and Gaimard, who accompanied Freycinet on his voyage, and published their observations in the 'Annales des Sciences Naturelles,' which are inconsistent with this theory. They found that the reefs did not entirely consist of coral, and that the layer of coral hardly exceeded a few fathoms in depth. Besides this the polypiaria which are able to form such a layer do not inhabit the sea to any great depth, and are not found where the water is more than 30 feet deep. They therefore supposed that these animals executed their work only in those parts of the sea where the bottom had been raised by some natural cause nearly to the surface of the water. They supported their theory by adducing the fact that the continuity of every lagoon-reef was broken at one or more places, so as to constitute a strait of very deep water, which could not be the case if these works were carried on at a depth of from 100 to 200 fathoms. This theory coincides with the views adopted by Von Buch, in his description of the Canary Islands, and has been adopted by Ehrenberg, in his pamphlet 'Ueber die Natur und Bildung der Coralleninseln und Corallenbanke im rothen Meere;' and by Darwin, in the third volume of the 'Surveying Voyages of the Adventure and Beagle.' The last-mentioned writer however does not doubt that the reefs which form the lagoon islands are composed of coral to a great depth, much greater indeed than those polypiaria which form them can live in. He explains this in a very ingenious way, by supposing that they formerly had an elevated island in the middle, but that in those portions of the sea where they now occur, the bottom of the waters was gradually lowered by subsidence, by which the polypiaria were enabled to continue their work farther, and the mountainous islands in the middle disappeared. In other parts of the Pacific and Indian oceans the contrary is supposed to have taken place: the bottom of the sea was elevated, and in these tracts volcanic islands occur. He observes that in this respect these seas may be divided into broad bands, in which an elevation and submersion has alternately taken place; and he draws from it some important inferences (p. 562-569).

REFLECTION. [OPTICS.]

REFLECTING INSTRUMENTS, viz., reflecting circle and sextant. [SEXTANT.]

REFLECTING TELESCOPE. [TELESCOPE.]

REFORMATION is the name generally given to the great schism which took place in the Western Church in the first half of the sixteenth century, and by which about one-fourth of the population of Europe has become separated from the Church of Rome. The countries in which the doctrines of the Reformation have become predominant, being the creed of the great majority of the people, are Sweden, Denmark, Norway, England, Scotland, the kingdom of Prussia, the kingdoms of the Netherlands, Hanover, Saxony, Würtemberg, the electorate of Hesse Cassel, the grand-duchies of Hesse Darmstadt and Mecklenburg; the land-graviat of Hesse Homburg, the duchies of Nassau and Brunswick; the principalities of Anhalt, Lippe, and some others; the free towns of Hamburg, Bremen, Frankfort, and Lübeck; the Russian Baltic provinces of Livonia, Esthonia, Courland, and Finnland; the Swiss cantons of Bern, Zürich, Basle, Schaffhausen, Aargau, Thurgau, Grisons, Vaud, Glarus, Appenzell, Neuchatel, and Geneva. The countries in which the reformed doctrines are followed by part, but not the majority of the population, are Hungary, Transylvania, the grand-duchy of Baden and some minor German states, France, the Swiss canton of St. Gall, and Ireland. Besides these, the great majority of the people of the United States of North America, as well as of the English and Dutch colonies, follow the same mode of faith.

In order to understand correctly the history of the Reformation, it is necessary to be acquainted with the social, political, and intellectual state of Europe in the fifteenth century; and for this purpose the histories of the Councils of Constance and of Basle, and the 'Historia Bohemica,' by Æneas Sylvius Piccolomini, are of great service. [PIUS II.] Previous to the Reformation, the see of Rome claimed of divine right, and asserted, with the assistance of the lay power of the various states of Europe, an absolute authority over the whole Christian Church, and consequently over the population of all Europe, with the exception of the provinces of the Turkish empire, the dominions of the czar of Russia, and of part of Poland, where the Eastern or

Greek church was established. By virtue of this supreme authority, the Roman pontiff decided absolutely all doubts and disputes which might arise, whether in matters of doctrine, jurisdiction, or discipline: his decisions were considered as infallible; and whoever resisted or gainsayed them was considered a heretic, and as such liable to canonical censures, and also to the temporal penalties awarded by the canon law against heretics. The government of the church was therefore absolute; and the church, or rather, the bishop of Rome, as head of the church, assumed also a supremacy even in temporal matters, although the exercise of this last supremacy was resisted by various princes. [GREGORY VII.; INNOCENT III.; INNOCENT IV.; GREGORY IX.]

The great object of the reformers of the sixteenth century was to overthrow the principle of absolutism in the government of the church, by contesting the infallibility and supremacy of the bishop of Rome. This had been already contested, and indeed set aside by the Councils of Constance and of Basle; but the point of contention had never been finally and permanently settled. [POPE.] The reformers of the sixteenth century however went much farther; they denied the absolute authority even of the councils, and they leaned towards the popular or democratic principle in religious matters, by allowing the right of individual interpretation of the Scriptures, and discarding all tradition and human authority in matters of faith. And here it must be observed that previous to the sixteenth century several of the most strenuous opposers of Roman absolutism in matters of jurisdiction and discipline, such as Gerson, chancellor of the university of Paris, in his work, 'De Modis uniendi et reformandi Ecclesiam in Concilio Universali,' never questioned the right of the church in council assembled to decide upon matters of doctrine, and to enforce decision against all dissenters even by means of temporal penalties. In his letter to the archbishop of Prague, on the Hussite controversy, which is given by Cochlæus, 'Historia Hussitarum' (lib. i.), Gerson recommends the axe and the stake as the last effectual means of extirpating heresy: 'Superest igitur, velut in desperata peste, securis brachii secularis, excidens hæreses cum auctoribus suis, et in ignem mittens. Providens hac tanta severitate et misericordi, ut sic dicatur, crudelitate, ne sermo talium, veluti cancer, serpat in perniciem tam propriam quam alienam.' This spirit of intolerance is therefore not peculiar to the Roman see, but is a consequence of the absolute principle of the Latin or Roman Catholic church. In our own times, Llorente, the historian of the Inquisition, whilst censuring the practice of that tribunal, which he considers as illegal, thinks it proper that the respective bishops should prosecute heretics; and the Spanish Cortes of 1812, when they abolished the court of the Holy Office, stated, as one of their reasons, that the diocesan courts were the proper authority for prosecuting and repressing heresy. But the reformers of the sixteenth century denied this absolute authority of church, council, or bishop, and as in the course of their struggle they were met by several dogmas or doctrinal tenets derived either from passages of the Scriptures as interpreted by the Roman church, or from tradition, or from decisions of the councils or decretals of the popes, which were urged in opposition to them, they set about translating and commenting on the Scriptures, substituting a different interpretation of the disputed passages, and thus sapping the very foundations of the whole fabric of church authority. A sketch of the manner in which the Reformation began in Germany is given under LUTHER.

It has been maintained by several writers that the principles asserted by Luther and other reformers were those of the early ages of the church: but all that can be proved seems to be that in almost every age since the apostolic times there has been here and there a display of opposition to the absolute system in the church; that some peculiar doctrines of Luther and Calvin had been asserted by others long before them; and that the Valdenses especially and their neighbours of the valleys of Dauphiné had retained from time immemorial a system of church discipline similar to that established by the Reformation in the churches of Switzerland and Scotland. [VALDENSES.]

Principal Epochs in the History of the Reformation.—Luther began his course of opposition to Rome by his memorable theses against the sale of indulgences, which he affixed on the doors of the cathedral of Wittenberg in Saxony, 31st of October, 1517. [LUTHER.] In 1519, Luther, in his disputation with Eckius, questioned the supremacy of the pope over the church, as well as the doctrines of purgatory, auricular confession, and absolution; and he afterwards published several treatises, in which he expressed his dissent more openly.

In June, 1520, pope Leo X. issued a bull condemning as heretical forty-one propositions extracted from Luther's writings. Luther appealed from the pope to the General Council, and publicly burnt Leo's bull (December, 1520). On the 6th of January, 1521, Leo expelled Luther from the communion of the church. In April of the same year Luther appeared before the diet of the empire at Worms, defended the substance of his tenets, and maintained that both popes and councils were liable to err. He was ordered to leave Worms, which he did unmolested, as he had a safe conduct; but after his departure he and his adherents were put under the ban of the empire.

Contemporary with Luther, Zwingli was pursuing a like course in Switzerland. It was in 1518 that Zwingli, without knowing then anything of Luther's proceedings at Wittenberg, opposed the sale of indulgences in the church of Einsiedlen, and preached against the abuses of that practice. In 1519, Zwingli, being transferred to the Gross Münster, or collegiate church of Zürich, began to preach openly not only against indulgences, but against the numerous outward forms of church worship, which, he said, 'fatigued the body without enlightening the mind or purifying the heart.' About the same time Bullinger at Bremgarten, Œcolampadius at Basle, Glareanus at Glarus, Wyttenbach at Bienne, and Berthold Haller at Bern, preached similar principles: they insisted upon the Liturgy being translated into the usual language of the people, and gradually proceeded to question the right assumed by the Roman pontiff of deciding all questions of religion. The court of Rome, whose attention was engrossed by Luther's German schism, did not for some years notice what was going on in Switzerland; but the bishop of Constance forbade the preaching of the new doctrines, and ordered the Papal bulls against Luther to be duly registered and promulgated. It appears that the bishop considered the new opinions in Switzerland as derived from and identical with those preached by Luther in Saxony. This however was not exactly the case, for the Reformation of Switzerland was of native growth, and independent of the German Reformation; and it differed from it from the first in some of its doctrines.

At Zürich, in 1522, Zwingli published his 'Apologeticus Archileles,' in defence of his doctrine. Conferences were held between Zwingli and his friends (who now assumed the name of 'Evangelicals'), and Faber, vicar-general of the bishop of Constance, and other papal advocates, but no approximation was effected between the two parties. In 15[illegible] the great council or legislature of Zürich forbade the preaching of any doctrine which was not clearly founded on the Scriptures, and removed the images from the churches. Shortly after they abolished the service of the mass, as well as processions and pilgrimages, promulgated a new Liturgy, and suppressed convents. In 1526 conferences were held at Baden between the Evangelicals and several Roman Catholic doctors and monks. An account of the proceedings was published at Luzern: 'Caussa Helvetica Orthodoxæ Fidei contra Martinum Lutherum, Zwinglium, Œcolampadium, &c.'

In January, 1528, the Council of Bern appointed a new and final conference to be held in that city, and invited the four bishops of Switzerland, Basle, Lausanne, Constance, and Sion, as well as deputies from the clergy of all the cantons, to attend. The four bishops declined, and six cantons, namely, Luzern, Zug, the three Waldstätten, and Freyburg did not send any deputations. Zwingli came from Zürich, accompanied by twenty-five deputies: Basle, Schaffhausen, Appenzell, Glarus, Soleure, as well as the Grisons, and the towns of St. Gall, Bienne, and Lausanne, sent each its deputation. It was altogether a solemn assembly, the most important that had ever met in Switzerland on this momentous controversy. Regulations for the maintenance of order and the mode of proceedings were enforced by the magistrates of Bern. It was at the same time proclaimed that 'no argument should be admitted in the conference which was not grounded on a text of Scripture,' to the exclusion of other authorities. This exclusion militated strongly against the Roman Catholic disputants; the conference however lasted nineteen days, and the Evangelical doctors displayed more learning than their adversaries. A son one Roman Catholic priest of Sillaure observed bitterly, that had his brethren, and especially the higher clergy, devoted more time to study and less to their pleasures, the result of the conference would have been different.

The conference being closed, the Council of Bern, considering the result to be in favour of the Evangelicals, published the following theses, which had been discussed; and they approved and confirmed them. 1. The holy Christian Church, of which Christ is the only head, is born of the word of God, and continues to adhere to it, and does not listen to the voice of the stranger. 2. The Church of Christ makes no laws and ordinances which are not grounded upon the word of God; therefore all the ordinances of men which are called by the name of commandments of the church are not obligatory unless it be proved that they are founded on the word of God. 3. Christ alone is our wisdom, our justice, our redemption, and satisfaction for the sins of the whole world; it follows therefore that to acknowledge other merits as means of salvation and satisfaction for sin is to renounce Jesus Christ. 4. It cannot be proved from holy Scriptures that the body and blood are contained materially and bodily in the eucharistic bread and wine. 5. The mass, such as it is now, in which the sacrifice of Jesus Christ is daily offered to God the Father for the sins of the living and the dead, is contrary to Scripture. 6. Jesus Christ, having alone died for us, must be alone invoked as our mediator and intercessor with God the Father. It is therefore without any foundation on Scripture that we are told to invoke other mediators and intercessors from among the dead. 7. There is no scriptural evidence for asserting that there is after this life any purgatory or place in which souls are purified by fire. Therefore all the services for the dead which have been introduced, as vigils, masses, funeral processions, oblations, anniversaries, lamps, wax tapers, and other such things, are useless and vain. 8. To make and set up images, in order to bestow upon them a religious honour or worship, is contrary to the word of God both in the Old and the New Testaments; they ought therefore to be abolished whenever there is danger that the people should bestow upon them a religious honour. 9. Marriage is not forbidden by Scripture to any class or order of men; it is, on the contrary, recommended to all, in order to avoid fornication and lewdness. 10. A public fornicator is excommunicated by the Scriptures; and there is no order of men in whom lewdness is more pernicious than it is in clergymen, on account of the influence of their bad example and of the disorders consequent upon it.

These ten propositions embody the substance of the Reformation, not only in Switzerland but in the rest of Europe; for with the exception of the fourth, concerning the eucharist, which differs from the Lutheran doctrine in the Augsburg Confession on that particular point, all the principles contained in them are acknowledged by all the reformed churches, however these churches may differ among themselves on some other abstruse points, such as predestination and grace, or on subjects of church discipline. The doctrines expounded in these ten propositions constitute their common ground of union in opposition to the doctrine and practice of the Roman Church, and they also exhibit at one view the fundamental points on which the Reformed Churches dissent from Rome; for the question of the supremacy and infallibility of the pope is evidently contained or implied in the second proposition. These points of dissent are neither few nor unimportant, and are expressed perhaps more clearly, soberly, and concisely in the above Swiss declaration than in any of the more elaborate confessions of faith subsequently promulgated by the various Reformed Churches.

Conjointly with the publication of the above ten propositions, the great and little councils of Bern published, on the 7th of February, 1528, an edict of Reformation based upon them, consisting of thirteen articles, declaring, among other things, that the spiritual jurisdiction of the bishops of Constance, Basle, Lausanne, and Sion over the subjects of the state was abrogated; that the deans and other members of chapters should take an oath of allegiance to the little council or executive of Bern; that all rectors, curates, and other presbyters were not to teach or preach anything contrary to the ten theses already approved, under pain of being deprived of their benefices; that monks and nuns might remain in their convents if they liked, but without receiving any novices or boarders; that those who wished to leave their convents were at liberty to do so, and to take away what they brought with them at the time of admission. It also declared that the mass and images were finally abolished at Bern, but that as there were in the country districts various populations which were yet uninstructed, the council did not wish to act harshly towards them, but, praying to God that they might become enlightened, left them the power of abolishing or retaining the mass or images, according to the vote of the majority. In the meantime, it enjoined both parties not to insult or revile each other.

Although the ceremonies of the mass, the offices for the dead, &c. were abolished, yet the endowments and gifts for those objects, quit rents, fees, tithes, and other dues continued to be paid as formerly, 'in order,' said the edict, 'that those clergymen of the old communion who had benefices might enjoy their income during their lifetime, and live and die in peace.' After their death, the council of Bern reserved to itself the disposal of the property according to justice and for the benefit of the state. Those persons however who had given property to convents or had founded chaplainships and other minor benefices without cure of souls might resume their gifts if they chose. Those cures or benefices which were annexed to convents were to be disposed of by the council, but no lord, patron, or collator of any church was to appropriate to himself or dispose of any part of its revenues. The precious vases and other utensils and ornaments of the churches were to remain in their places for the present; but permission was given to those companies, corporations, and families that owned altars and chapels, to claim the ornaments and utensils attached to them. The clergy as well as nuns were allowed to marry. Every person was allowed to eat of all sorts of meat without distinction of days, but excess and drunkenness were forbidden. Taverns and other public places were to be shut up at nine o'clock in the evening. All clergymen having the care of souls were to preach four times a week, Sunday, Monday, Wednesday, and Friday, except during the seasons of sowing, reaping, and vintage, the peasants being then unable to attend church on week-days. (Ruchat, *Histoire de la Réformation en Suisse*.)

These regulations of the government of Bern, which were similar to those adopted by Zürich, being conceived in a spirit of mildness, charity, and liberality, reflect great credit on the spirit that governed the Swiss Reformation, of which Bern and Zürich were the main pillars, and contrast advantageously with the harsh and rash fanaticism of many reformers in other countries. Even Roman Catholic states in our own times, when engaged in suppressing the monastic orders in their territories, might have learned from the equitable and humane conduct of the dissident government of Bern towards the convents of that state, a lesson of honourable forbearance, which however they have been far from following.

There are many persons at present in Protestant countries, and especially in England, who from reading the history of England, and more particularly the period of Henry VIII., have conceived a kind of prejudice against the English reformation, which they are apt to identify with the capricious and cruel acts of that tyrannical prince. Led by his own violent passions and intent on his selfish gratification, Henry VIII. effected a schism with Rome on matters of jurisdiction by asserting his own supremacy, but not on doctrinal points, in which he continued to adhere to the tenets of the Roman church. He did not produce or encourage the Reformation; on the contrary, he persecuted and put to death the real reformers. He seized the property of convents, but bestowed it chiefly upon laymen, his own courtiers. The Reformation in England sprung from among the people and the clergy. It had begun with Wycliff; it spread from England to Germany among the Lollards and the Hussites, and was carried back from the Continent to the shores of Britain with a fresh impulse from the preaching of Luther, Bucer, and the Swiss reformers. The schism of Henry VIII. paved the way, but it did not originate nor promote nor establish the doctrines of the Reformation; they made their way rather in spite of, than by the favour of that capricious king. It was only under his successor, Edward VI., that the Reformation found favour with the throne, and became established by authority. Still the origin of the church of England as a body independent of Rome dates from the wayward deeds of Henry VIII., and when that church afterwards adopted the reformed doctrines, there was a great admixture of political and state reasons in the final establishment of it, especially under Elizabeth, and consequently much severity and harshness were exhibited towards those who adhered to the old religion, which threw for a time a dubious light over the ascendency of the Reformation in England. But the case was very different with the Reformation in Germany and Switzerland. Those countries were the native soil and the battle-field of the Reformation: there the first reformers took up their ground at once on doctrinal points against Papal Rome; they were obscure individuals assailing the stupendous fabric of ages, and when they afterwards gained the favour of some princes of the empire, they had still against them the fearful odds of the Imperial authority backed by all the influence of the House of Austria and of a powerful hierarchy, and by the numerical majority of the population of Germany.

While Zwingli and his friends were propagating religious reform in Switzerland, Luther was proceeding in his career in Germany. In 1521-2 he wrote against auricular confession, clerical celibacy, monastic vows, and prayers for the dead. In 1523 he preached against the mass, which was about that time abolished by the Austin friars in their church of Wittenberg. A number of monks quitted their convents and married. Frederic, called 'the Wise,' elector of Saxony, without openly countenancing the schism, tolerated these proceedings. Pope Adrian VI. sent a Nuncio to the Diet at Nürnberg to rouse the States against the Lutherans, acknowledging at the same time that many abuses had crept among the clergy, which should be reformed. But the majority of the Diet besought the pope to convoke a general council, and drew up a list of no less than a hundred grievances, which are known by the name of 'Gravamina Centum.' The Diet separated, postponing the consideration of the new doctrines to the next session. In 1524 Luther divested himself of his monastic dress, and in the following year he married. Frederic, elector of Saxony, died in 1525. John, who succeeded him, openly embraced the Reformation and commissioned Luther to prepare a new church service for his dominions. Luther also published his two catechisms for the use of schools, as well as his German version of the New Testament. His friend Melanchthon co-operated zealously in establishing the Reformation in Saxony. Martin Bucer was pursuing a similar course at Strasburg. [BUCER; MELANCHTHON.] Between the years 1525 and 1529 Luther's doctrines spread rapidly through Germany. The elector palatine, the landgrave of Hesse, the duke of Deux Ponts, the margrave of Brandenburg and grand-master of Prussia, and numerous cities, adopted the Reformation. The descendants of the Hussites of Bohemia inclined to the same course. The doctrines of Luther spread also to Sweden, where the canon Olaus Petri, archdeacon Anderson, and others of the clergy adopted them; and at last king Gustavus Vasa, having assembled a synod at Orebro, the Reformation was solemnly proclaimed in 1528. It ought to be observed that the rapid diffusion of the Reformation through Germany, though proceeding in a great measure from the popular feeling, was also greatly favoured by the self-interest of the various princes, who eagerly seized upon the wealth of the suppressed convents, collegiate churches, and other ecclesiastical establishments—a selfish motive which no one deplored or censured more bitterly than Luther himself. In the case of Sweden the ascendency of the doctrines of the Reformation was promoted by the feeling of national independence against the Danes, who were favoured in their designs by the intrigues of the Catholic clergy. [GUSTAVUS ERICKSON.] In the history of the Reformation, as in that of other great human contests, we perceive an admixture of various causes and influences, of good and evil, of conviction and self-interest, of spirituality and sensualism.

In March, 1529, at the diet of the empire, assembled at Speyer, the Roman Catholic princes proposed that those who should continue to embrace or favour the new doctrines should be placed under the ban of the empire; but the opposition raised by the elector of Saxony, the landgrave of Hesse, the margrave of Brandenburg, and the deputies from the imperial cities, caused the motion to be rejected. The next object of the Roman Catholics was to divide the Lutherans from the followers of Zwingli, or Sacramentarians, as they were called, who denied the real presence, and whose doctrines had spread to Strasburg, Constance, Lindau, Memmingen, and other towns of Germany; for if the Lutherans could be made to join in the proscription of the Zwinglians, they might afterwards be assailed in their turn. Accordingly a ·ree was drawn up proscribing the Anabaptists, a fanatical sect which had committed great disorders in the Netherlands and other parts, and which may be considered as a wild offshoot of the Reformation. The decree also condemned the denial of the real presence in the eucharist, and prescribed that the mass should be preserved, and that ecclesiastics both Lutheran and Roman Catholic should not annoy each other for their respective belief, until a council or another Imperial Diet should finally decide upon the matters in dispute, and that the gospel should continue to be preached according to the sense of the most approved doctors of the church. The Lutheran princes and deputies however, perceiving the policy of the Roman Catholics, refused to sanction the decree, especally as it was so expressed as to condemn indirectly some of their own tenets. The Roman Catholic princes, who formed the majority, insisted on the decree, and it was then that the reformed princes and deputies, making common cause without distinction of Lutherans or Sacramentarians, delivered in a formal 'protest,' dated from the Diet of Speyer, April 19, 1529, from whence the denomination of 'Protestants' has been derived. In that celebrated document they maintained that the decree of the preceding Diet, which connived at toleration until the meeting of the General Council, having passed unanimously, could only be abrogated by unanimous consent: that they could not accede to the sweeping condemnation of the Anabaptists and Sacramentarians without their being summoned and heard in their defence; that as the Romish mass was contrary to Scripture, they could not attend it themselves nor let their subjects attend its celebration; that the clause which stipulated that the gospel should be preached only according to the interpretation of the church, did not remove the main difficulty, as the question was, which of the churches was the true one. This protest was signed by John, elector of Saxony; George, margrave of Brandenburg and grand-master of Prussia; Ernest and Francis, dukes of Luxemburg; Philip, landgrave of Hesse; Wolfgang, prince of Anhalt; and by the deputies of fourteen cities, Strasburg, Nürnberg, Ulm, Constance, Reuttingen, Hildesheim, Melingen, Lindau, Kempten, Heilbrunn, Weissenburg, Isny, Nordlingen, and St. Gall. (Spalatinus, *Annales Reformationis;* and also *Vitæ aliquot Electorum Saxoniæ.*)

The landgrave of Hesse, feeling the necessity of unanimity among the reformers for their common preservation, endeavoured to effect an approximation between the Lutherans and the Zwinglians. After some hesitation on the part of Luther, a conference was agreed on at Marburg between Luther and Melanchthon on one side, and Zwingli and Œcolampadius on the other. Melanchthon has given an account of this conference. Zwingli and his friends were disposed to make concessions to Luther in regard to the questions of original sin, justification by faith, and absolution, on which they differed; but when they came to the eucharist, they could not agree. Luther adhered to the literal sense of the words 'This is my body,' which however he explained, by saying that the real body co-existed with the elements of the bread; and this he called consubstantiation, which was different from the Roman Catholic transubstantiation. Zwingli maintained that the words had a figurative meaning, and that the bread was only the type of Christ's body. Upon this Luther grew warm, and expressed his astonishment at Zwingli's presumption in opposing the interpretation of all the doctors and commentators from the earliest ages of the church. He seems however to have been ignorant of the controversy that had already been raised on the subject in the ninth century by Paschasius Radbert, a Benedictine monk and abbot of Corbie, who published a treatise 'Concerning the Sacrament of the Body and Blood of Christ,' which he presented to Charles the Bald, and in which he positively maintained that which had not been previously decided by any council or general authority, namely, that after the consecration of the bread and wine, nothing remains of those elements except the outward figure, under which the body and blood of Christ, such as when he suffered upon the cross, were really and locally present. Charles commissioned two of the ablest writers of his time, Ratramn, or Bertram, a monk of Corbie, and Joannes Scotus Erigena, to investigate the assertion of Radbert. The work of Scotus is lost, but it appears that he was opposed to the real presence. Ratramn's opinion was qualified: he asserted the real presence, but he denied the identity of the body with that which suffered on the cross, and especially the consequence deduced by Radbert, that Jesus Christ was seen fiœd anew every day at the consecration. The treatise of Ratramn is still extant. Hincmar and other theologians engaged in the dispute, some for and others against Radbert; and the question was revived in the eleventh century by Berenger, who denied the bodily presence, professing to follow the opinion not only of Scotus, but of Augustin, Jerome, and Ambrose; until Gregory VII. obliged him to retract before a council, and to subscribe to the identical propositions maintained by Radbert. [BERENGER; CONSUBSTANTIATION.]

Luther and Zwingli separated without coming to an understanding, Zwingli observing that both parties were agreed in the fundamental principles of Christianity, and that in others they might have charity for each other, and might be united under the common denomination of reformers and brethren. Luther offered to part in Christian charity, but not in brotherhood: they shook hands in presence of the landgrave, and agreed to refrain from open controversy.

In the following year, 1530, Charles V. convoked a diet of the empire at Augsburg for the month of April, and directed the Evangelical members of the same to bring with them a written profession of their faith in German and Latin. The most eminent theologians, both Roman Catholic and Reformed, were summoned. Luther alone, in consequence of the former decree of the diet of Worms of 1521, was forbidden to appear in person; but the elector of Saxony directed him to remain at Coburg, in order to be consulted in case of need. The Reformed divines of the various states set about writing a summary of their doctrine; and the task of examining all these papers, and of extracting from them 'a good and explicit confession of faith,' which should be acceptable to all German reformers, was entrusted to Melanchthon. When the Confession was written, John, elector of Saxony, sent it to Luther at Coburg to be revised. Luther approved of it without any exceptions. On the 25th June, 1530, the elector, accompanied by his son John Frederic; by George, margrave of Brandenburg; by Ernest and his brother Francis, dukes of Brunswick and Lüneburg; Philip, landgrave of Hesse; Wolfgang, prince of Anhalt; and the deputies of the town of Nürnberg and some other free cities, came into the Diet, and presented that important document to the emperor, who directed the chancellor to read it aloud to the assembly. Melanchthon had softened some of the points of dispute, in order to conciliate, if possible, the good will of the Roman Catholic party. The Confession of Augsburg was published in 1531, 'Confessio Augustana,' and consisted of twenty-eight articles. The real presence in the sacrament without transubstantiation, justification by faith alone, the number of sacraments, communion of both kinds, and the invocation of the saints, were the chief points comprehended in it. The Roman Catholic theologians undertook to refute the positions of the reformers, who replied by an 'Apology for the Confession,' which was likewise written by Melanchthon. Seeing that there was no hope of an agreement, Charles V. and the Roman Catholic princes issued an edict in November, 1530, which, without denying the abuses and corruption which had crept into the church, promised that the emperor would insist on the pope calling a general council for their correction, and in the mean time enjoined all parties to conform to the regulations of the Roman church, and not to write or preach against any article of the antient faith, or to admit any novelties in doctrine or discipline: it further exhorted them to unite in suppressing the heresies of the Anabaptists and Sacramentarians. The latter had also presented their confession of faith to the Diet on the part of the four cities, Strasburg, Memmingen, Lindau, and Constance, which is generally known by the name of the Confession of Strasburg, or 'Confessio Tetrapolitana.' The German Protestant princes, alarmed by the edict of the emperor, assembled at Smalkald, in December, 1530, with the elector of Saxony at their head, and entered into a league, both religious and political, with the determination of defending their rights and the liberty of conscience, by force if necessary, against all attacks. Thus in the year 1530 the Reformation was finally established in Germany, first by the Confession of Augsburg, which was published as the acknowledged and common creed of a great body of Christians; and secondly by the league of Smalkald, which made that creed the bond of union of a powerful political confederacy.

The landgrave of Hesse invited the Reformed cantons of Switzerland to join the league of Smalkald; but as they refused to sign the Confession of Augsburg, the elector of Saxony declined to admit them into the Protestant league, and thus the Swiss Evangelicals continued distinct from the Lutherans, though they joined in a separate league with the city of Strasburg, and the landgrave of Hesse, who adopted their doctrines. In a great synod held at Bern in 1532 (Zwingli had died the year before), the Helvetic confession of faith was finally proclaimed; being mainly based upon the ten theses or propositions agreed upon at Bern in 1528, and which have been given above. In 1566 a new edition of the Helvetic Confession, signed by all the Reformed states of the Swiss Confederation, was published at Zürich: 'Confessio et Expositio simplex orthodoxæ fidei et dogmatum Catholicorum sinceræ religionis Christianæ, concordita ab ecclesiæ Christi Ministris qui sunt in Helvetia, Tiguri, Bernæ, Glaronæ, Basiliæ, Scaphusii, Abbatiscellæ, Sangalli, Curia Rhætorum, et apud Confederatos Mylhusii, item ac Biennæ; quibus adjunxerunt se Genevensis et Neocomensis ecclesiæ ministri, una cum aliis evangelii Præconibus, in Polonia, Hungaria, et Scotia,' 8vo. Tiguri, 1566, republished in 1651. A French translation was lately published at Lausanne, 'La Confession de Foi Helvetique,' 1834. It is the same as that of the French Protestants, as they are commonly though improperly called: 'La Confession de Foi des Eglises Reformées de France,' Montpellier, 1825. The Helvetic Confession consists of thirty chapters, an abstract of which is given in the 'History of Switzerland,' published by the Society for the Diffusion of Useful Knowledge, Appendix iv. The same work contains a full account of the rise, progress, and final settlement of the Reformation in Switzerland. The Reformed doctrines had early spread to Geneva, through Bonnivard, and afterwards through Farel, a native of Dauphiné, who had come to Geneva about the year 1530. After several years of noisy and turbulent controversy, attended by violence and even bloodshed, the great council forbade the mass, images, &c. in 1534. It was only in 1536 that John Caulvin or Calvin made his appearance at Geneva on his return from Italy, from whence he had escaped through fear of the Inquisition. Farel induced him to settle at Genoa as professor of theology. Both he and Farel went further than the Swiss reformers. They abolished all festivals except Sunday, discarded all church ceremonies, used leavened bread for the sacrament, and maintained the doctrine of predestination in all its sternness. This drew upon them the disapprobation of the Evangelical synod, then assembled at Lausanne for the purpose of regulating the discipline of the Helvetic Church. As Calvin and Farel however would not submit to the decision of the synod, the council of Geneva ordered them to leave the town in 1538. Farel settled at Neuchatel, where he remained till his death. Calvin went to Strasburg, where he established a French Evangelical church; but in 1541 he was invited to return to Geneva, where he became the civil as well as religious leader of the republic. The rest of the career of this remarkable man is given in the article CALVIN. His peculiar tenets concerning religious doctrine and church government, as expounded by him in his 'Institutiones,' are noticed in the article CALVINISM. Calvinism became the creed not only of Geneva but of the French Huguenots, as they were styled, a word said to be derived from Eidgenossen, or Confederates, which was the name assumed by the popular party at Geneva which brought about the Reformation. Calvinism spread also into the Netherlands and parts of Germany, and afterwards into Poland, Hungary, and Transylvania, and it was brought by Knox into Scotland. Calvinism thus became the third great branch or division of the Reformation, Luther and Zwingli being the heads of the other two. The doctrines of predestination and grace are its distinguishing dogmas. The distinction however between the Zwinglians and the Calvinists is not material, and they are now considered as one, having the same confession of faith.

In France, as early as 1530, the doctrines of the Reformation had found their way from Germany and Switzerland. Some of those doctrines had lingered in the south for ages before, especially in the mountains of Dauphiné bordering on the Valdenses. Pierre Robert d'Olivet, Michel Cop, rector of the University of Paris, Beza, and others, adopted and spread them; and Margaret, sister of Francis I., and Renée, daughter of Louis XII., gave them their countenance. But Francis I., who through policy secretly encouraged the Protestant states of Germany against the emperor, persecuted his own subjects who had embraced the new doctrines. The stake and the faggot were employed at the same time in France and in England, by Francis and Henry VIII. against the reformers. In 1535, Francis, attended by his family, the clergy, the magistrates, and other officers of state, was present at the burning by a slow fire of six citizens of Paris, who had been condemned by the parliament as heretics. The execution lasted two hours. This was the forerunner of many scenes of a similar character which disgraced France for more than half a century. In 1545 the villages of Merindol and Cabrieres in Provence were burnt, and the inhabitants of both sexes were massacred on account of heresy, in consequence of an order of the parliament of Provence and of Francis I. The persecutions, the civil and religious wars, the truces and other vicissitudes of the French Calvinists, during the reigns of Francis I., Henri II., Francis II., Charles IX., and Henri III., are part of the history of France. [BARTHELEMY, ST.] De Thou, in his 'Historiæ sui Temporis,' Beza, 'History of the Reformed Churches of France,' and the recently published 'Mémoires et Correspondence de Duplessis Mornay pour servir à l'Histoire de la Reformation et des Guerres civiles et religieuses en France depuis l'an 1571 jusqu' en 1623,' Paris, 1824-34, are the best contemporary authorities for that period. At last Henri VI., by his 'Edit de Nantes,' 1598, acknowledged the Reformed communion as the lawful creed of a part of the French population.

In Germany, during the same period, the course of Protestantism did not run smooth, although there were no stakes lighted nor massacres perpetrated. The Protestant states were too powerful, and Charles V. had too much need of their support against the Turks and his other enemies, to quarrel with them on the score of religion, and push the dispute to extremities. By the treaty of Nürnberg, 1532, the obnoxious decree of Augsburg, of 1530, was revoked so far that the Lutherans were to retain their present power and privileges, but were not to make any further innovations in faith or discipline than were contained in the Confession of Augsburg, nor send missionaries into Roman Catholic states, nor encourage the subjects of Roman Catholic princes to take refuge in their territories, nor to support the Anabaptists or Zwinglians; and that all proceedings in the Imperial chamber on the score of religion should cease.

This pacification of Nürnberg, as it is called, lasted till 1546, the year of Luther's death. That great reformer was busy during this period in consolidating his church by his teaching and writing, and by his influence over the Protestant princes, who consulted him in all matters of religious polity, and in completing his great work, the German translation of the Bible. He also effected, in concert with Bucer, a union with the Sacramentarians of Germany, who came to a compromise on the subject of consubstantiation.

The Swiss however, or Zwinglians, refused to sign the articles on which Luther and Bucer had agreed, and they continued separate. Still the union of all Protestant Germany under one banner was a great step, and the accession to the Protestant party of Maurice, duke of Saxony, the elector palatine, and Ulrick, duke of Würtemberg, greatly added to its strength. Their power was shown in the war which followed against the emperor; for although in the first instance (in 1546), through the defection of Maurice of Saxony, whom Charles had won over, the Protestant league was defeated, it afterwards recovered itself. The league took the field again with Maurice at its head in 1552, and obliged Charles to sign the treaty of Passau in August of that year, by which it was agreed that the Protestants should retain their liberties and possessions, until the meeting of a diet, which should establish a perpetual religious peace, and that during the interval there should be no more disputes about religion. In 1555 the promised diet assembled at Augsburg, and framed the articles of a religious peace for Germany, which, after some modifications, were subscribed by both parties. The terms were: that neither emperor nor Roman Catholic prince should attempt to force back Protestants into the bosom of the Roman Catholic church, nor Protestants force Roman Catholics to renounce their faith; that every prince should have the power of establishing, in his own state, which of the two communions he thought proper, and of granting toleration to the other if he pleased; that those subjects who professed a creed different from that established in their state, might retire unmolested with their property, and settle in another state where their faith was professed; that no Roman Catholic bishop should have jurisdiction over those who follow the Confession of Augsburg; that Protestant clergymen should retain possession of their benefices, and Protestant princes the right of administering the property of the church of which they were actually possessed; that if a Roman Catholic ecclesiastic abandoned his faith, he should lose his dignity, and his benefice should be conferred upon another, but that his reputation or civil rights should remain untouched; that the Imperial chamber should do justice to both parties, and the members of it without exception might be Protestant as well as Roman Catholic.

Such were the conditions of the peace of Augsburg, by which the Protestant religion was acknowledged in the German empire, and when we reflect that these conditions were agreed upon about three centuries ago, by Protestants and Roman Catholics, by clergy and laity of both communions, by bishops and princes of the empire, we cannot help being struck with the equity and reasonableness of those who framed it, as honourable alike to German feeling and German judgment. This peace was broken many years after by the war which is known by the name of the Thirty Years' war (1619-48), but the treaty of Westphalia, which terminated the war, confirmed the articles of the religious peace of Passau and Augsburg, and extended its benefits to the Calvinists as well as the Lutherans. The princes, states, and towns of the empire of the three communions were placed on a footing of equality by this treaty. In all matters of religion, and in other disputes between Roman Catholics and Protestants or Calvinists, the diet was to decide not by a majority of suffrages, but by amicable accommodation. In extraordinary commissions appointed by the diet, the commissioners were to be all Protestants, if the matter concerned Protestants only; all Roman Catholics, if it concerned Roman Catholics only; and an equal number of each, if it concerned both religions. Toleration and the exercise of private worship for every individual were also secured.

The consequence of this tolerant arrangement has been that since the peace of Westphalia religious persecution has been unknown in Germany, and German Roman Catholics, accustomed to live in peace and intercourse with their Protestant neighbours and fellow-subjects, exhibit none of that fanatical horror which the ignorant population of Spain and of many parts of Italy still evince at the very name of a heretic.

The doctrines of the Reformation had made many converts in the Netherlands in Luther's lifetime, and a fresh influx of Calvinists from France and Switzerland increased the number of dissidents from the Roman church. The wild outbreak of the Anabaptists at Leyden, Münster, and other places threw discredit for a time on the cause of the Reformation, but these disturbances were soon put down. During the reign of Charles V., the friends of the new doctrines in the Netherlands were persecuted as heretics, and many suffered death by sentence of the regular courts of the country; but after Charles abdicated, at Brussels in 1555, in favour of his son Philip, the latter, in order to extirpate heresy more effectually, sent inquisitors from Spain to establish the tribunal of the Holy Office in the Netherlands. This gave rise to a strong opposition both from the nobles and the people, which, being mixed up with political grievances, led to an open insurrection against Philip. During the long war which followed between the rebels and the Spanish forces, some of the provinces separated from the rest, and the seven northern provinces of Holland, Zealand, Guelderland, Friesland, Utrecht, Overyssel, and Groningen formed a confederacy by the name of the 'Seven United Provinces,' and proclaimed liberty of conscience. The great majority however of the population of the seven provinces followed the doctrines of Calvinism, and have remained attached to them ever since. The confession of faith for the provinces of the Netherlands was published in 1562, and was afterwards approved by the members of the synod of Emden in 1571. The disputes that broke out afterwards between the Arminians and Gomarists are related in the article ARMINIUS. The synod of Dort, in 1618, revised and republished the Netherlandish Confession.

About the year 1556 the Lutheran or Protestant creed was adopted as the state religion in the kingdoms of Denmark and Norway, under king Christian III. Denmark however, as well as Sweden, has retained episcopacy.

The Protestants or Lutherans, as well as the Calvinists, became very numerous in Poland under the reign of Sigismund

Augustus, and many of the high nobility had embraced the Reformed doctrines. An approximation was effected between the Lutherans and Calvinists, and a confession was drawn up, in concert, by the clergy of both communions, at Sandomir, in 1570, called 'Consensus Sandomiriensis.' The followers of the Reformation however never constituted the majority in Poland, and being afterwards persecuted under Sigismund III. and some of his successors, their number was greatly reduced, but they were never annihilated, and Lutheran and Calvinist congregations have continued to exist in most towns of Poland. The most complete account of the Reformation in Poland is in the recent work of Count Krasinski (*Historical Sketch of the Rise, Progress, and Decline of the Reformation in Poland*, London, 1838).

In Hungary and Transylvania both Lutherans and Calvinists have long been established, and they constitute at present about one-fourth of the population of those countries, enjoying equal rights with the members of the Roman Catholic and Greek churches.

The doctrines of the Reformation spread into Italy from Switzerland and Germany at an early period, and found proselytes in several towns, especially Ferrara, where Renée of France, duchess of Este, countenanced them; at Lucca, Faenza, Milan, and Naples. Several learned monks and priests, the Capuchin Ochino of Siena, Vermigli, a canon of Florence, Montalcino, a Franciscan friar, Lorenzo Romano, an Augustine monk, and others, adopted and preached the new tenets. Meetings and private places of worship were established in various towns. Paul III., alarmed at this change, established, in 1543, the Congregation of the Holy Office at Rome, with full powers to proceed against heretics independent of the ordinaries, and he also sent inquisitorial commissioners into the various provinces of Italy for the same purpose. [OFFICE, HOLY.] By these means he effectually checked the course of the Reformation, and his successors Paul IV. and Pius V. completed its extirpation by the most severe measures. Many of the followers of the Reformed doctrines suffered death either by fire or by the sword of the executioner. [PIUS V.] Numerous families emigrated to Switzerland on account of religion, especially from Tuscany and Lombardy. A considerable district of Calabria, near Cosenza, which is said to have been originally peopled by a colony from the valleys of Piedmont, having publicly adopted the tenets of the Reformation, and sent for some Calvinist preachers from Geneva to teach them and their neighbours, the duke of Alcala, Spanish viceroy of Naples, about 1560, sent several inquisitors with a body of armed men, who arrested and put to death many people in the village of San Sisto. Upon this the neighbouring villages broke out into open revolt. The town of La Guardia Lombarda sustained a regular siege. Being taken at last, a general massacre of the inhabitants took place, with circumstances of the greatest atrocity. (Botta, *Storia d'Italia*, b. x.)

At Locarno, an Italian district on the Lago Maggiore, subject to the Swiss Catholic cantons, the Reformation had made numerous proselytes, but in 1555 an order came from the ruling cantons for banishing all the Evangelical families from Locarno. The heads of those families being assembled in the town-hall, the sentence was read to them, and they were preparing to obey it, when a priest entered the hall, and suggested that the wives and children of the heretics should be detained in order that they might be converted. But the Swiss Roman Catholic deputies shuddered at the proposition: 'We will not alter the sentence which has been pronounced,' they replied; and the exiles, accompanied by their wives and children, set off across the Alps, and took refuge chiefly at Zürich, where the families of Orelli, Muralti, and others still retain their name and traditions.

In the district of Valtellina, which was subject to the Grisons, the Reformed doctrines were openly professed by many, and encouraged by their rulers. But the two parties, Roman Catholics and Protestants, having become identified with the political parties in the Grisons, one of which was favourable to an alliance with Austria and Spain, and the other opposed to it, feeling ran high, acts of violence were committed, and the Roman Catholics, being the more numerous in Valtellina, conspired against the Grison government, and in July, 1620, massacred all the Protestants in the valley, their own countrymen as well as Grisons, to the number of several hundreds. The Reformed religion was thus extirpated in the Valtellina also, and all Italy has ever since remained exclusively Roman Catholic, with the exception of the valleys of Pignerol, the inhabitants of which, after many persecutions, have been allowed to retain and profess their antient faith.

In Spain the doctrines of Luther and Calvin spread in the sixteenth century, and made numerous proselytes at Seville and other places; but the arm of the Inquisition effectually eradicated them. M'Crie has written the history of the rise, progress, and extinction of the Reformation both in Spain and in Italy.

For the progress and final settlement of the Reformation in England, we must refer to the history of this country, and the articles BUCER, CRANMER, CROMWELL (THOMAS), EDWARD VI., ELIZABETH of England, GARDINER, HENRY VIII., MARY I. of England, and POLE, REGINALD. For the Reformation of Scotland, see KNOX and MARY STUART.

Independently of the religious question of the truth or falsehood of the doctrinal points on which the Reformed churches dissent from that of Rome, a question upon which it is not our business here to express an opinion, it is unquestionable that the Reformation, as an historical fact, has exercised a most powerful influence upon the moral, political, and intellectual condition of mankind. The invention of printing, the discovery of America, and the Reformation are three events which, following each other in succession, may be said to have effected a complete change in the face of the civilised world. A writer who is by no means partial to Luther and the other reformers individually, thus speaks of the effects of the Reformation:—'Let the Roman Catholics argue as they please about the unity and universality of their religion, the records of the middle ages prove that, in the majority of men, it was a lifeless tissue of ceremonies, which, from their frequency, could not even strike the imagination; which made assuredly little impression on the heart, none whatever on the understanding. Since Luther's time, religion has been an object of the understanding rather than of the eye; of the heart rather than of the memory. The repetition of a prescribed number of prayers, almsgiving, a journey to some shrine, the veneration of a relic, might in former times satisfy for sin; but from the sixteenth century downwards, it has been admitted that, without true compunction, without reformation of life, such things are ineffectual and even puerile. In this respect the Roman Catholics have gained as much as the Protestants; they have learned spirituality; they have forsaken their cold, unmeaning, and useless observances, for a principle—that of divine love—which pervades the heart; for knowledge, which informs the understanding. In the second place, there has been no less improvement in the conduct than in the feelings and reasonings of men. The tenets of the Reformation produced vices enough, but they were vices less odious than those which previously disgraced society. As religion was in danger of being smothered under an accumulated heap of human observances and opinions, so were morals of perishing through the boundless licentiousness of the period. In this respect too the present Roman Catholic has need to bless the memory of Luther and his colleagues in the Reformation. Cast our eyes wherever we may, we find an amazing improvement in the general state of morals. . . . . In the third place, the Reformation has been exceedingly favourable to civil liberty. The same principle of curiosity which taught men to examine the grounds of their faith, urged them, in an equal degree, to weigh the nature and design of civil government. It was soon discovered that despotism was founded on ignorance; that it had no divine right to support it; that, on the contrary, it was repugnant alike to reason and the word of God. If that word inculcated obedience to the highest powers, it also taught that the poorest and lowest subjects had rights inalienable and sacred; that in the eye of heaven the highest and lowest are equal, all Christian brethren coheirs of another and a better kingdom, equally on earth the objects of the Divine solicitude. . . . . In the fourth place, and as a necessary consequence of this augmented knowledge alike of religious and political rights, was the increased stimulus given to individual exertion. Despotism, whether civil or ecclesiastical, is a sad enemy to social enterprise, to individual activity. When man perceives that he has rights which cannot be invaded with impunity, that the profits of his industry are secured to him by recognised law and custom, he will require no spur to labour; and in proportion as he enriches himself, so will the state be benefited. . . . . Fifthly, the same moral revolution has led to an amazing increase of knowledge. To understand the Scriptures, which Catholics and Protestants admitted to be the common fountain of faith, the early reformers assiduously studied the original tongues, the Hebrew and the Greek, and the attainment served as a key to other departments of knowledge—to history, laws, geography, and antiquities no less than to theology. Prior to the sixteenth century, these languages were almost entirely neglected; they were even condemned by doctors of the church and by universities. The doctors of Louvain and even of Paris stigmatised the study of the Scriptures in the original tongues—in any other than the Vulgate—as the inevitable path to heresy. But this pitiful hostility soon gave way; the Catholics, no less than the Protestants, applied with success to the study of the Hebrew and Greek Scriptures; manuscripts were discovered and carefully collated, and the Divine text was restored to something like purity. . . . . From these and other considerations, it is evident that on the whole the Reformation has been an incalculable good to Europe; it has purified religion and morals; it has improved the intellect, and has guaranteed civil liberty.' (Dunham, *History of the Germanic Empire*, b. iii., ch. 2.)

Among those authors who have written or commented upon the history of the Reformation, the following deserve notice, besides those mentioned in the course of this article: among the Protestants—Beausobre, *Histoire de la Reformation*; Burnet, *History of the Reformation*; Seckendorf, *Commentarius Historico-Apologeticus de Lutheranismo*; Loscherus, *Acta et Documenta Reformationis*; and among the Catholics—Maimbourg, *Histoire du Lutheranisme*; Pallavicini, *Historia Concilii Tridentini*; Bossuet, *Histoire des Variations des Eglises Protestantes*; besides the general historians of the church. The following work, published at Paris about 1823, deserves special mention: *Musée des Protestans célèbres, ou Portraits et Notices Biographiques et Littéraires des Personnages les plus éminens dans l'Histoire de la Reformation, rédigé par une Société de Gens de Lettres, et publié par* G. T. Doin.

REFORMATION, HOUSES OF. [PUNISHMENT; TRANSPORTATION.]

REFRACTION, REFRANGIBILITY. Refraction is the turning of a ray of light, heat, or other imponderable substance from its direction, when it falls obliquely on the surface of a medium differing in density from that through which it had previously moved. The differently coloured rays of light have different degrees of refrangibility, as evidenced by the common prismatic spectrum; in other words, the refractive indices of different lights vary for a given medium. The fundamental law of refraction and the optical effects of this law are discussed under the heads LIGHT and OPTICS, and a table of refractive indices is given in the article OPTICS, PRACTICAL. For the different refrangibilities of the rays, the articles DISPERSION and ACHROMATIC may be consulted, and for one of the most striking phenomena thence arising see RAINBOW. On the subjects of Frauenhofer's lines and of double refraction see DISPERSION and POLARIZATION.

The doctrine of refraction, as distinguished from reflection, is called dioptrics, and the caustics formed by the continued intersections of refracted rays emanating from a luminous point, are termed diacaustics; properly speaking, these are surfaces, but by confining the investigation to the plane of refraction, they are generally treated as curves. A diacaustic curve, like a catacaustic, has the property of being rectifiable. They are noticed in the articles above quoted, but they are rather objects of analytical dexterity than of practical use.

So long as the medium into which the refracted ray enters remains of uniform density, the ray will pursue a straight course, but every alteration of density in the medium gives rise to a corresponding deviation in the path of the ray. Now the air is a medium of which the density continually increases as its altitude above the surface of the earth diminishes; its density is also altered in the same stratum by inequality of temperature, and frequently from the aqueous and other vapours which it holds. Hence arise the ordinary terrestrial refraction and the phenomena of MIRAGE, FATA MORGANA, &c., which are treated under their respective heads.

A ray of light proceeding from a star which is not vertical, on entering the atmosphere is bent towards the radius drawn from the earth's centre to its point of incidence, and upon its successive incidences on the lower strata it continues to bend towards the successive radii, thus describing a curvilinear trajectory through the air. The star is visible in the direction of the tangent to this curve, at the point at which it meets the eye of the spectator; hence the apparent altitude of the stars is increased by refraction, and thus the sun, moon, &c. are visible before the real time of rising and after that of setting.

From the causes above assigned for atmospheric refraction, it follows that the nearer the direction of the ray is to the plane of the horizon, the greater is its refraction, and the refraction is nothing when the ray is vertical. This is the cause of the apparently oval forms of the sun and moon in the horizon; for the sun's angular diameter being taken at 32 minutes, its lower limb is elevated through horizontal refraction more than its upper by 4 minutes 54 seconds.

Atmospheric refraction of the solar rays after sunset, combined with subsequent reflection, is the cause of twilight, and also of the light thrown on the moon's surface when eclipsed by the earth.

The amount of refraction of rays proceeding from a celestial body would be proportional to the tangent of its zenith distance, if the atmosphere were homogeneous: not only however is this not the case, but its state is continually altering, as shown by the barometer, thermometer, and hygrometer. An empiric formula, the result of numerous observations made by Bradley, gives a good correction relative to the first two of these instruments, viz.:—

Let $r = 57'' \times$ tang. zenith dist. (z);
$h =$ height of thermometer (Fahrenheit);
$a =$ altitude of barometer in inches;
$R =$ the required refraction; then shall

$$R = 57''. \frac{a}{29{,}6} \cdot \frac{400}{350 + h} \cdot \tan (z - 3r) \text{ nearly.}$$

Similar formulæ have been the objects of analytical research to Laplace and other modern mathematicians; their results are however not well adapted for insertion in this work.

REFRIGERANTS are remedial agents which directly diminish the force of the circulation, and reduce the heat of the body or a portion of it, without occasioning any diminution of the ordinary sensibility or nervous energy. This definition must not be considered as excluding *cold* from among the number of such agents, because it is capable, when carried to extremes, of rendering the sensibility null and utterly extinguishing the nervous power; it is only its moderate and therapeutical employment which is here contemplated.

The manner in which refrigerants effect the ends which they accomplish is far from being understood; and a remarkable feature in their character is, that they display their peculiar effects chiefly when the action of the organs is above their natural standard, and more heat than naturally evolved. Till we have a perfect knowledge of the sources and mode of formation of animal heat, we are not likely to possess a correct theory of their mode of operating; and at present, whatever plausibility the mere chemical hypothesis of Dr. Murray exhibits, we cannot consider the evolution of animal heat to be other than a vital process. This function is mainly carried on in the capillaries or extreme vessels, and is much influenced by the amount of supply of nervous energy to these vessels. Hence when a limb is paralysed, it is colder than the opposite sound member; or when a single nerve is injured, the parts supplied by it have a lower temperature than the surrounding ones. Whatever therefore hinders the free communication of the nervous power to a part or to the whole system, will lessen its quantum of animal heat. By applying to the surface of the body any acid the calibre of the capillaries is lessened, and hence the paleness which is observed, owing to less blood entering them. As the blood furnishes the pabulum from which the nerves evolve the heat, the less fuel the vessels contain, the less potent will be the heat resulting. The introduction of any article of the class of refrigerants into the stomach appears to operate by sympathy on the whole vascular system, as may be seen in the case of dilute sulphuric acid checking hæmorrhage. The agents which are usually regarded as refrigerants are weak vegetable acids, or very greatly diluted mineral acids; some saline, neutral, or super salts; and cool air, ice-cold water, and externally evaporating lotions. An indirect refrigerant is found in diminishing the quantity of animal food. [ANTIPHLOGISTICS; BATHING; LOTIONS.]

REFRIGERATION OF THE GLOBE. Since the mathematical researches of Fourier regarding the diffusion and conduction of heat in a mass constituted as the earth appears to be in the parts near the surface, have become in some degree known, geologists have been much encouraged in attempting to connect with a gradual change and diminution of the internal temperature of the globe, such as would be consistent with Fourier's theoretical results, the higher order of geological inferences. The phenomena of a general if not universal base of once melted rocks below all the strata, the peculiar (often called metamorphic) condition of the lowest of these as compared with the upper, the absence or rarity of fossils in the lowest strata, the evidence of even general high surface temperatures on the antient land and in the antient sea as contrasted with the modern distribution of climates, are all consequences supposed to be derivable from the assumption of the earth having once been thoroughly very hot, and being now partially cooled by radiation of heat into the cold planetary and stellar spaces around us. But though such a deduction of phenomena from a primal condition of our planet is or appears to be correct enough to justify geologists in employing the hypothesis as a means of discovering truth, they must be careful neither to disregard inquiries into the certainty of the fundamental assumption, nor to neglect a scrupulous examination of its consequences.

On the first point Professor Whewell communicated to the Geological Section of the British Association at Dublin (1835) some observations which are likely to be influential on the second point, and which can neither be condensed nor amended.

'The heat of the interior parts of the earth has always been treated of by those who have established the theory of heat upon mathematical principles. They have hitherto considered it as proved upon such principles, that the increase of temperature of the substance of the earth as we descend proves the reality of an *original heat.* But M. Poisson, in his 'Theorie de la Chaleur,' just published, dissents from this opinion, and is disposed to assign another reason for the higher temperature below the surface. He observes that the cosmical regions in which the solar system moves have a proper temperature of their own; that this temperature may be different in different parts of the universe; and that, if this be so, the earth would be some time in acquiring the temperature of the part of space in which it has arrived. This temperature will be propagated generally from the surface to the interior parts. And hence, if the solar system moves out of a hotter into a colder region of space, the part of the earth below the surface will exhibit traces of that higher temperature which it had before acquired. And this would by no means imply that the increase of temperature goes on all the way to the centre.' (*Reports of the British Association for* 1835, p. 66.)

A speculation, perhaps in reality involving such views as those of M. Poisson, though founded on examinations and inferences among the Helvetic Alps, has been of late brought prominently before the geological world by M. Agassiz. According to this very distinguished naturalist, there is evidence from the peculiar effects left by glaciers in the valleys of Switzerland and on the surface of the Jura Mountains, that the icy mantle which now wraps the High Alps once filled the valleys for miles beyond its present limits, and rendered it a mere glacier movement across an ice-filled hollow, which carried the blocks of Mont Blanc and the Valorsine across the Lake of Geneva to the Jura. Recently Dr. Buckland and Mr. Lyell have endeavoured by similar evidence and reasoning, by the evidence of scratched, smoothed, and grooved surfaces of rock, and the appearance of moraine heaps both in the Highlands of Scotland, near Edinburgh, and in Cumberland and Westmoreland, to prove that glaciers antiently covered large tracts of the Caledonian and Cumbrian regions. (*Geol. Proceedings,* 1840, November and December.)

Moreover, it is understood to be the opinion of M. Agassiz that the icy covering thus attempted to be demonstrated by its remaining effects in the mountainous parts of Great Britain, 'once extended over all the north of Europe and the north of Asia and America,' and that in this 'mass of ice the elephants and other mammalia found in the frozen mud and gravel of the arctic regions were imbedded at the time of their destruction.' To the quick melting of this immense mass of ice and the currents of water which resulted, the author attributes the transport and deposition of the 'masses of irregularly rounded boulders and gravel which fill the bottom of the valleys, innumerable boulders having at the same time been transported, together with mud and gravel, upon the masses of the glaciers then set afloat.' (See the work of M. Agassiz entitled *Etudes sur les Glaciers de la Suisse;* and the accounts of his observations before the British Association at Glasgow in 1840.)

Now it is obvious that in examining this speculation, two ways are open: first, a careful comparison of the phenomena with the hypothesis which is proposed for their explanation; secondly, an inquiry into the probability of the conditions which might render such a general and extreme refrigeration of the globe as the hypothesis requires *possible.* Confining our remarks to the former process, we may observe: first, that to admit the antient existence of glaciers in some of the Highlands and Cumberland valleys which display *glacial effects,* is one thing; to admit *glacial action* as the physical cause of the dispersion of boulders and gravel, another. Glaciers are found at this day in corresponding latitudes and at corresponding elevations in the southern parts of America; a local effect of causes which may be conceived to have formerly produced an equal effect in the northern zone: but the distribution of the boulders and gravel is so peculiar and yet so various, the dispersion of them so wide in regions where, according to the present configuration of the land, they could not be pushed by glaciers, nor carried by floating ice; and the connection of these circumstances with a great change of organic life, so strict, that it is hardly conceivable such effects could be due to anything but a cause simultaneously general or successively repeated. Of the physical causes by which the explanation of this great phenomenon has been attempted, it will suffice to mention three:—

1. Great and extensive oceanic action consequent on mighty misplacements of the solid land, and corresponding changes of land and sea.

2. Repeated local displacements of land and sea, and consequent litoral action.

To each of these views has been attached a speculation of the auxiliary agency of floating ice.

3. The melting of great circumpolar glaciers, and the drifting of floating ice.

Our object being to call unprejudiced attention to this subject, we shall only append a few short remarks.

1. The researches of Mr. Smith of Jordan Hill, Captain Bayfield, Mr. Lyell, and others, have shown the probability that in much of the gravel which contains sea-shells, in Northern Europe and America, these shells are not indicative of a warmer but a colder climate than the present.

2. The circumstances under which the extinct mammalia occur in the caverns of tropical Brazil are entirely analogous to these which have been noticed in temperate Europe.

3. The simultaneous gathering of ice over all the northern zone could only happen as a consequence of a *general cooling of the surface of the globe,* and the laws of melting ice are such as to render it almost inconceivable that *even by a rapid change* of temperature such prodigious floods *could be occasioned* as the transport of blocks seems to require; moreover, would not such a rapid change of temperature be excluded by the condition of a previous general refrigeration?

4. The proper course to be now pursued by geologists is to refer to other branches of science the determination of the probability or admissibility of the fundamental assumption of this hypothesis (that the earth has undergone *vicissitudes of temperature* and suffered extensive circumpolar refrigeration); and in the spirit of inductive philosophy, which has hitherto guided their researches, to analyse, classify, and map the boulder formation, so as to arrive at correct inferences regarding the direction, nature, and origin of the forces concerned in producing it.

REGA'LIA, the ensigns of royalty. This term is more especially used for the several parts of the apparatus of a coronation. In England, the regalia properly so called are the crown, the sceptre royal, the virge, or rod with the dove, St. Edward's staff, the orb or mound, the sword of mercy, called Curtana, the two swords of spiritual and temporal justice, the ring of alliance with the kingdom, the armillæ or bracelets, the spurs of chivalry, and sundry royal vestments. The regalia here enumerated, all but the vestments, are preserved in the Jewel-Office in the Tower of London. Before the Reformation in the time of Henry

VIII., they were constantly kept by the religious of the abbey of Westminster; and are still presented before the king on the morning of the coronation by the dean and prebendaries of that church.

In 1649 a complete inventory was made out of the regalia in the Tower, a copy of which may be seen in the additional notes to Taylor's *Glory of Regality*, 8vo., Lond., 1820, p. 312; subsequent to which it is stated that the crowns, according to order of parliament, were 'totallie broken and defaced.' On the restoration of kingly government in the person of Charles II., new insignia were made for his coronation, and these, with the necessary alterations to accommodate them to their successive wearers, and to repair the injuries of time, have continued to the present day.

REGALS (*Regale*, It.), a small portable finger-organ, well known during the sixteenth and seventeenth centuries, and probably much earlier, but not now in use: though Snetzler, the celebrated organ-builder, informed the Hon. Daines Barrington, about the year 1770, that it was not then entirely lost in Germany (*Archæologia*, iii. 32); and till sixty years ago, if not later, there still existed an officer in the royal household called 'Tuner of the Regalls.' In Rees's Cyclopædia this instrument is described as having 'pipes of reeds for convenience of carriage,' an error arising from a mistaken application of the organ-builder's term 'reed stops,' or stops in imitation of hautboys and other instruments blown through a reed.

REGEN, THE CIRCLE OF THE, so called from the name of one of its rivers, is a province of the kingdom of Bavaria, composed of parts of the antient duchy of Bavaria, the Upper Palatinate, the principality of Sulzbach, the territory of Ratisbon, and some other parcels of territory. It lies between 48° 37′ and 49° 44′ N. lat., and between 11° 17′ and 12° 50′ E. long. It is bounded on the north by the circle of the Upper Main, on the north-east by Bohemia, on the south-east by the circle of the Lower Danube, on the south by that of the Isar, on the south-west by that of the Upper Danube, and on the west by that of the Rezat. The area, according to Hassel, is 4170 square miles. The Danube passes through the circle from Ingolstadt to Wirth, and divides it into two unequal parts. The southern portion, which is the smaller, is generally level and very fertile; the eastern and northern part is rugged and mountainous, being traversed by elevations which are partly a continuation of the Fichtelgebirge, and partly of the Bohemian Forest. The soil to the north of the Danube is generally poor, and extensive tracts are covered with sand or with bare uninterrupted rock. Accordingly, though agriculture is followed in the whole circle, it is only to the south that it is extremely productive, and that the finest wheat is grown. To the north, towards the Fichtelgebirge and the Bohemian forest, rye, oats, potatoes, flax, hemp, and hops are grown, and here and there tobacco; but the labour of the husbandman is very severe, and the harvest sometimes fails. The vine is not much grown, for the few vineyards on the Danube are of no importance; fruit too is not cultivated to any extent. The great forests constitute the wealth of the northern part, as they enable the inhabitants to keep up numerous iron-works and glass-houses. The breeding of cattle might be carried on more extensively than it is; that of oxen and swine is most attended to. Fish and game abound. The mineral kingdom is very rich, but no mines are worked except those of iron and coal: those of copper, lead, and sulphur are neglected. There are good quarries of freestone and marble. On the whole there is a more active spirit of industry in this circle than in Bavaria in general. Besides the iron and glass manufactories, there are potteries, paper-mills, and in some districts considerable linen manufactures. The breweries are very important, and the beer of this circle is among the best in Germany. The brandy-distilleries are numerous.

The population is 449,600, of whom a very great majority are Roman Catholics.

REGENSBURG. [Ratisbon.]

REGENT, REGENCY. These words, like *rex*, contain the same element as *rego*, 'to rule,' *regens*, 'ruling;' and denote the person who exercises the power of a king without being king, and the office of such a person, or the period of time during which he possesses the power. Wherever there has been hereditary sovereignty, or an hereditary kingly office, it has been found necessary sometimes to have recourse to the expedient of appointing a regent. The cases are chiefly those of (1) the crown devolving on a minor too young to execute any of the duties belonging to it; (2) mental incapacity of the person in whom the sovereignty or kingly office is vested; (3) temporary illness, where there is a prospect of the long continuance of the disease, and of incapacity in consequence; (4) absence from the realm. But in the first case the regent has usually been called in England by the name of Protector: the latest instance being the minority of Edward VI., when his uncle the duke of Somerset was the Protector. By the act of parliament recently passed, Prince Albert is appointed regent during the minority of the princess royal in the event of the demise of the queen, but not with the title of protector. His functions are however the same as those of the protectors of former times, allowing for the changes which have taken place in the English constitution in the course of the last three centuries.

In the earlier periods of English history we have several instances of protectors during minorities, and some of regencies during the temporary absence of the king. The occasional absences of George I. and George II. on visits to their continental dominions rendered the appointment of regents a matter of convenience, if not of necessity. Sometimes the power was put, so to speak, in commission, being held by several persons jointly; but queen Caroline sometimes possessed the functions of regent during the absence of George II.

The nature of this part of the English constitution was however so little understood, and the practice was so imperfectly defined, that when George III. was incapacitated for discharging the duties of royalty on the first occasion when his malady became the subject of public notoriety, a question arose, on which the chief constitutional and political authorities of the time were divided in their judgment. The question was this—whether the heir apparent, being of full age, and the king's eldest son, did not become of right regent. The Whig party of the time, led by Mr. Fox, contended that he did. On the other side, it was maintained that it lay with parliament to nominate the person who should be regent. No regent was at that time appointed, the recovery of the king intervening. When the king was a second time incapacitated, all parties agreed in conferring the title, office, and privileges of regent on the Prince of Wales, then heir apparent. But it was done by parliament, who laid certain restrictions upon him during the first year; but in the event (which event did happen) of the continued incapacity of the king, he was to enter into the full possession of all rights and privileges of king, as if the king were dead, using however only the name of regent, not king: so that in reality the constitution of the country remained unaltered.

The time when the Prince of Wales held the office of regent is the period of English history which will be meant hereafter by the expression 'the regency,' just as 'the regency' in reference to French history denotes the time of the minority of Louis the Fifteenth, when the duke of Orleans was regent. It was during the English regency that the power of Napoleon was broken, and peace was restored to Europe.

REGGIO. [Modena, Duchy of.]

REGGIO. [Calabria; Rhegium.]

REGIMENT, a body of troops, whether infantry or cavalry, forming the second subdivision of an army; the union of two or more regiments or battalions constitute a brigade, and two or more of the latter making up a grand division or corps d'armée. A regiment is commanded by a colonel, a lieutenant-colonel, and a major, whose several ranks are graduated so as to correspond to those of the general officers commanding the army or division; and when a regiment is divided into two or more battalions, each of these has, at least when complete, its own lieutenant-colonel and major. The word denotes, in general, any government, but it is now applied only to a body of men, indefinite in number, who are subject to military regulations and immediately under the control of a colonel. The precise period when bodies of men were so designated, for the first time, is uncertain, yet no doubt exists that the common application of the term took place in France after the middle of the sixteenth century.

According to Père Daniel, the first formation of corps of troops corresponding in organization to the modern regiments occurred in the reign of Henry II. of France; and that writer states (*Histoire de la Milice Françoise*, tom. ii., liv. xi.) that, very soon after the battle of St. Quintin (1557), in which the Constable de Montmorenci was defeated and nearly all the French infantry was dispersed, that king issued an ordonnance for the institution of seven legions of foot soldiers, each to consist of 6000 men, who were to be raised, or to do duty, in the frontier provinces of the kingdom. Each of these legions, which was commanded by a colonel, was divided into 15 companies, and to each of the latter were appointed a captain, a lieutenant, and an ensign. [COMPANY.] In this respect the legions differed from those which Francis I. had attempted to raise; for though each of the latter was to have consisted of 6000 men, it was to be commanded by six captains, one of whom only had the title of colonel; and under each captain there were to be two lieutenants and ten centurions. The legions of Henry II. were never completed to the extent prescribed by the ordonnance, and the number of companies in each was, soon after its promulgation, reduced to six.

Though these legions had most of the characteristics of a modern regiment, it appears that they were quite distinct from the bodies of troops which, about the same time, bore this name; and P. Daniel conceives that the regiments were first formed from the companies, or bands, as they were called, of which, from the time of Francis I., or earlier, to that of Henry II., the infantry of France chiefly consisted. Each of these bands was commanded by a captain, who, according to Brantome, was *mestre de camp* over his soldiers; that is, he had no officer above him except the colonel-general of infantry; and the bands were distinguished by the designation of old and new, according to the dates of their formation.

The embodyment of the bands in regiments could not, it is supposed, have been later than 1562, which was in the beginning of the reign of Charles IX.; and Daniel gives, in support of this opinion, the words of the historians Davila and Daubigné, who, in stating the events of the years 1562 and 1563, mention by name the regiments of Picardy and of Brittany; the former writer also, in speaking of the renewal of the civil war in 1567, says that the queen sent in haste for the colonels De Brissac and Strozzi with the *old* regiments. These last are supposed by Daniel to have been the regiments formed of the old bands above mentioned, and to have been so called in contradistinction from others which may have been more recently raised. In proof that regiments then existed independently of the legions, he remarks that, in the registers of the French army for the year 1567, mention is made of an officer who was colonel of the legion of Picardy, and of another who is called colonel of the regiment of Picardy. The regiment of French guards was raised in 1563, by Charles IX., for the defence of his person; and the legions of Guienne and Dauphiné, which had been instituted by Henry II., and disbanded in 1562, were by the same prince restored under the name of regiments, the former in 1567 and the latter in 1568. Charles also organised other regiments, and it is probable that during his reign the denomination became general. The word *terzo*, which according to Sir James Turner (*Pallas Armata*, 1683) was in his time applied by the Spaniards to a regiment, seems to indicate that the numerical strength of the latter was considered as equal to the third part of that of some other body, as a legion.

The time when the name and institution of a regiment were adopted in England cannot be fixed with precision; but Sir James Turner, in the work above quoted, remarks that the word regiment was not then a hundred years old; and if it is meant that the word had been nearly a century in use in this country, it would follow that it was introduced about 1583, or about 20 years after it began to be used in France. In the account of the pay of the officers of the army which was raised by Queen Elizabeth in 1588, when the country was threatened with the Spanish invasion, mention is made of the colonel and lieutenant-colonel of the regiment (Grose, *Military Antiquities*, vol. i., p. 348); and both colonel and regiment occur in Morrison's account of the army in Ireland, in 1598. From the time of that queen's reign the British army has been invariably divided into regiments; and this practice has been followed by all the other nations of Europe.

The army which it was proposed to raise in 1620 for the protection of the Palatinate was to have been formed of 12 regiments of infantry, each consisting of 13 companies, of which the first, or the colonel's company, was to be composed of 200 men, and the others of 150 men; and there were to be 50 troops of horse, each consisting of 100 men. At this time, and perhaps earlier, the word battalion came into general use to denote either the whole or some division of a regiment: Sir Walter Raleigh, in his 'History,' calls the maniples of the Roman troops at the battle of Zama small battalions. Each of the four regiments of infantry which were raised by Charles I. to serve against the Scots consisted of 1850 men; and, in 1659, during the civil wars in this country, the parliamentary forces consisted of nine regiments of horse, each divided into six troops of 80 men, and 14 regiments of foot, 12 of which consisted of 1200 men, and two of 1100 men, all exclusive of officers. Each of the regiments was divided into ten companies; and there were, besides the regiments, five bodies, each containing 500 men, and three others, each containing 300 men: these eight bodies were called companies, and probably they corresponded to the companies or independent bands in the French army before the institution of regiments.

Soon after the Restoration all the regiments were disbanded; two of them however, one of which is designated the lord-general's regiment of foot and the other his life-guard of horse, were immediately (1661) re-engaged in the service of the crown; and in the same year the Scotch corps or band of 1700 men, which in the time of James I. had gone into the service of France, returned to England. (Daniel, tom. i., liv. x.) This body was then denominated the First or the Royal Regiment of Infantry; and it boasts of being the oldest regular corps in Europe.

In 1684, or near the end of the reign of Charles II., that part of the English army which was assembled near London was reviewed on Putney Heath; and a list of the officers commanding the several regiments is given by Grose (vol. ii., Appendix No. x.). The first named are three troops of horse-guards, which apparently were the lord-general's life-guards above mentioned. These were afterwards disbanded, and instead of them there were raised two troops of horse-grenadier guards; and in 1788, when the latter were reduced, the two regiments of life-guards at the head of the present list of the British regiments were raised. The second at the review was the Earl of Oxford's royal regiment of horse-guards, which was divided into eight troops; and these are the royal horse-guards which constitute the third regiment in the present list. The third was Lord Churchill's regiment of dragoons, which was divided into six troops; and which is at present denominated the First or the King's Dragoon-Guards.

The infantry consisted of the following corps, viz.:—Two battalions of the royal regiment of guards, now called the grenadier guards; one battalion of the Coldstream regiment of guards, which regiment still bears that name; one battalion of the Earl of Dumbarton's regiment, or the royal regiment of infantry above mentioned; and one battalion of the Duke of York's, or the admiral's, maritime regiment. This last, which was named in compliment to the king's brother (afterwards James II.), was subsequently disbanded or converted into a regiment of marines. No other regiments were at the review, but there then existed the queen's regiment of foot, since denominated the queen's royal regiment of infantry: the Holland regiment, which was raised in 1665, and was so designated because it had served in that country. This was then considered as the fourth regiment of infantry, after the two regiments of guards, but it was afterwards and is still designated the third, in consequence perhaps of the reduction of the admiral's regiment. The same regiment is also called the *Buffs*, from the colour of the facings on the dresses of the men. In the year 1684 a regiment of infantry was raised in Ireland; and this appears to have been the seventh, but not being considered as in the pay of England till some years afterwards, and other regiments having in the interval been raised, it became the eighteenth on the list. This is now designated the Royal Irish regiment; the epithet royal having been given to it for its gallant behaviour at the siege of Namur in 1695.

The augmentations which have since taken place in the British army consist of one additional regiment of guards (infantry), called the Scots Fusiliers; of fifteen additional regiments of cavalry, making, exclusive of the guards, sixteen regiments; and, of infantry, as many as make ninety-nine regiments, independently of the foot-guards, the royal regiment of artillery, and the royal corps of marines. Three of the regiments of cavalry, including the first above-mentioned, are heavy dragoons, five are light dragoons, four are hussars, and the remaining four are lancers. Of the in fantry regiments, eight are distinguished as light infantry, four are called fusilier regiments, and one, the 60th, is called the king's rifle corps: there is also a rifle brigade in England, and a rifle regiment (of native troops) in Ceylon; a regiment of fencibles at Malta, and three West India regiments (of coloured troops). To these should be added the Honourable East India Company's regiments, a corps of mounted riflemen at the Cape of Good Hope, and the African colonial corps.

As the legions of Henry II. of France bore the names of the several provinces where they were raised, so most of the regiments composing the line of the British army are distinguished by the names of the counties or districts in which the men were enlisted: thus the third is called the East Kent regiment; the fifth, the Northumberland; the sixth, the royal Warwickshire; and so on. The second of the guards also is called the Coldstream regiment.

For the divisions and evolutions of a regiment see BATTALION.

REGIOMONTA'NUS, or, as he styled himself in some of his works, Joannes Germanus de Regiomonte, is the adopted name of a celebrated German astronomer whose real name was Johann Müller. He was born June 6, 1436, but his biographers are not agreed as to the place of his birth. Some say Königsberg in Prussia (Starovolsci); others Königsberg in Franconia (Montucla); De Murr, in his 'Noticia trium Codicum,' afterwards referred to, says, Unfind near Königsberg, in the duchy of Saxe-Hilburghausen; while Doppelmayer and Niceron, followed by Delambre, say Königshofen in Franconia. His adopted name favours the supposition of his birthplace having been Königsberg.

When twelve years old he was sent by his parents to prosecute his studies at Leipzig, but whether he entered the university of that city does not appear. His progress in arithmetic, geometry, and astronomy is said to have been such, that before completing his sixteenth year he could meet with no one sufficiently learned to instruct him in these sciences, which induced him, about 1452-3, to remove to Vienna, where he became the pupil and intimate friend of Purbach, who was at that time professor of astronomy in the university of Vienna. Under Purbach's direction he applied himself zealously to the Greek astronomy, through the medium of such Latin versions of the 'Almagest' as existed; and commenced a series of astronomical observations, including several eclipses and a conjunction of Mars, which last led to the detection of an error of two degrees in the Alphonsine Tables.

Purbach had undertaken a new Latin translation of the 'Almagest,' but dying suddenly, the completion of the work devolved upon Müller. [PURBACH.] Upon Purbach's death (1461), Müller accepted the vacant professorship of astronomy in the university of Vienna, on condition of being permitted to reside for some time in Italy, in order that he might there, in compliance with Bessarion's suggestion, acquire a knowledge of the Greek language.

In 1461-2 he accompanied the Cardinal to Rome, where he began the study of the Greek language, and occupied himself in collecting, collating, and copying Greek MSS., and making astronomical observations, chiefly of eclipses, and where also he made the acquaintance of George of Trebizond, who had anticipated him in a translation of the 'Almagest' from the original, though the work was very imperfectly executed. In 1463, Müller proceeded to Ferrara, where for about a year he continued his philological studies under Blanchini, Theodore Gaza, and Guarino, at the expiration of which time he accepted an invitation from the students of Padua to give in that city a course of instruction explanatory of the astronomical writings of the Arabian philosopher Alfragan. The introductory discourse, entitled 'Oratio in Prælectionem Alfragani Introductoria in Scientias Mathematicas,' &c., delivered by him on this occasion, was prefixed by Melanchthon to his edition of Alfragan, published in 1537. From Padua he proceeded, in 1464, to Venice, to meet Bessarion, with whom he returned to Rome, and shortly afterwards returned to Vienna, where he entered upon the duties of his professorship. While in Italy he composed his work entitled 'De Triangulis Planis et Sphæricis,' first published at Nürnberg, in 1533, fol., 57 years after the author's death, which is now the most interesting of his works. It contained two tables of natural sines, one to a radius 6,000,000, the other to a radius 10,000,000, and by their means all the cases of plain and spherical triangles were solved, without the aid of a similar table of tangents, the utility of which he did not perceive, and the consequence of which oversight was that the solutions, though occasionally very ingenious, are in most cases excessively prolix. The solution of that case of spherical triangles in which, the angles being known, it is thence required to determine the sides, was first given in this work. The trigonometry and the tables of sines appear to have been published separately. The title of the latter, according to Niceron, was 'Compositio Tabularum Sinuum, cum Tabulis Duplicibus Sinuum ejusdem,' Nürnb., 1541, fol. A detailed analysis of the trigonometry is given in the 'Astronomie du Moyen Age,' pp. 292-323 and 347. It affords, says Delambre, a very complete view of what was then known of plane and spherical trigonometry, though the discoveries in this branch of science which belonged exclusively to Müller were not of great importance. While in Italy he likewise detected many errors in Trebizond's version of the 'Almagest,' which he severely criticised. This excited so much animosity, that some have attributed Müller's early death to poison administered to him by one of the sons of Trebizond. (Vossius, *De Scientiis Mathematicis*, p. 184.)

The earliest edition of Purbach and Müller's translation of the 'Almagest' appears to be that of Venice, 1496, fol. It was reprinted at Basle, in 1543, and there are several subsequent editions. The title of the two editions mentioned is 'Joannis de Monte Regio et Georgii Peurbachii Epitome in Cl. Ptolemæi Magnam Compositionem, continens Propositiones et Annotationes quibus totum Almagestum declaratur.' The first six books were the work of Purbach, who makes the length of the sidereal year 365 days, 6 hours, 9 minutes, 12 seconds, which is much nearer the truth than that given by his predecessors. He also states that the obliquity of the ecliptic given by Ptolemy is 23° 51′ 20″, but that, in his own time, he is unable to make it more than 23° 28′, though he does not say whether he considers the obliquity to be decreasing or Ptolemy's result to be erroneous. In all the demonstrations sines are employed to the exclusion of chords. (Delambre.) Upon the whole, this epitome is supposed to have been chiefly extracted from the Latin version which Gerard of Cremona had made of the Arabic commentary of Geber on the 'Almagest.' It appears in effect that both Purbach and Müller rather divined the sense and seized the spirit of Ptolemy than understood the letter of their text. The work was a model of precision, but nevertheless it was an abridgement, and an abridgement of Geber much more than of Ptolemy. (Preface to the French translation of the 'Almagest,' by M. Halma, Paris, 4to., 1813.)

After some years' residence at Vienna, Müller was invited by the king of Hungary (Matthias Corvin) to take up his abode at Buda, where he amused himself with collating the Greek MSS. which had been brought from Athens and Constantinople, and in constructing 'tables of directions,' in which he shows himself no less attached to astrology than to astronomy. The work is entitled 'Tabulæ Directionum Profectionumque, non tam Astrologiæ Iudiciariæ quam Tabulis, instrumentisque innumeris fabricandis utiles ac necessariæ,' &c., Nürnb., 1475, 4to. It contained the first table of tangents published in Europe, extended however only to each degree of the quadrant. But although similar tables had been constructed by the Arabs, and applied by them to trigonometry full 500 years earlier, Müller, as has been stated, was quite ignorant of this their chief use. The work is reviewed in the 'Astr. du Moyen Age,' pp. 288-92. It may here be observed that the term 'tangents' was not introduced till after the time of Müller. Both by him and Purbach, as by the Arabs, they were called 'shadows,' the length of the shadow of every object cast by the sun being in fact the tangent of the sun's zenith distance, the radius being the vertical height of the object. The state of Hungary induced him, in 1471, to remove to Nürnberg, where he formed an intimacy with a wealthy citizen, Bernard Walter, at whose expense several astronomical instruments were constructed and a printing-office established. With these instruments a series of observations were made which afforded abundant proof of the inexactitude of the Alphonsine Tables. They were published in 1544, under the title of 'Observationes 30 Annorum à J. Regiomontano et B. Walthero. Scripta de Torqueto, Astrolabio Armillari, Regula magna Ptolemaïca, Baculoque astronomico,' Nürnb., 4to. Müller's observations commence at Rome, 3rd January

1462, and at Nürnberg, 6th March, 1472, and terminate 28th July, 1475. Those of Walter begin 2nd August, 1475, and end 3rd June, 1504. Lacaille made use of these observations in the construction of his solar tables. (*Astr. du Moyen Age*, p. 337.) The appearance of a comet led him to compose a work entitled 'Problemata xvi. de Cometæ longitudine, magnitudine, et loco vero,' first published at Nürnberg in 1531, 4to., wherein he gives a method of determining the parallax of a comet, afterwards employed by Tycho Brahé, but which, observes Delambre, though true in theory, cannot be depended on in practice. (*Astron. du Moyen Age*, pp. 340-4.) Prior to 1475, he published his 'Kalendarium Novum,' for the three years 1475, 1494, and 1513 (the interval being an entire cycle of 19 years), which was probably the first almanac that appeared in Europe, though the idea was taken from a similar work composed by Theon of Alexandria. It gives the length of day at all places situated between the parallels of 36° and 55° N. lat.; and for every three degrees of the sun's longitude. On the appearance of this almanac, the king of Hungary presented Müller with 800 (some say 1200) crowns of gold; and such was the demand for it, that, notwithstanding the price of twelve gold crowns, the whole edition was speedily disposed of in Hungary, Italy, France, and England. Besides the above works of his own composition, he had printed an edition of Purbach's 'Theory of the Planets,' the 'Poems' of Manilius, &c., and was proceeding with others, when Pope Sixtus IV., who contemplated a reformation of the calendar, purchased his services by appointing him archbishop of Ratisbon. He immediately quitted his old patron Walter, and proceeded to Rome, in July, 1475, where he died on the 6th July of the following year, in the 41st year of his age. His body was interred in the Pantheon.

Müller, observes Delambre, was a man of remarkable sagacity, and of an ardent and enterprising disposition. He was without contradiction the most learned astronomer that Europe had then produced; though he was inferior to Albategnius as an observer, and to Aboul Wéfa as a calculator. It is matter of astonishment that having recognised the advantage of employing tangents in some few particular cases, he should not have seen the importance of introducing them into ordinary calculations. He had shown the inaccuracy of the Alphonsine Tables, had contemplated their improvement, and had instituted a systematic course of observations for that purpose; time and leisure were alone wanting to the realization of his views. His journey to Rome and premature death occasioned an injury to astronomy which it required a long interval to repair.

The following list of his works, not already mentioned, is taken from the list given by Delambre, in the 'Biog. Univers.,' compared with that given by Niceron With the exception of the first two, they were all published after his death:—1, 'Disputationes contra Cremonensia in planetarum theoricas deliramenta,' Nürnb., 1474, fol. 2, 'Tabula magna primi mobilis,' Nürnb., 1475. 3, 'Almanach, ab anno 1489 ad annum 1506.' 4, 'In Ephemerides Commentarium,' Venice, 1513, 4to. 5, 'Tabulæ Eclipsium Purbachii. Tabulæ primi mobilis à Monteregio,' Venice, 1515, fol. 6, 'Epistola de compositione et usu cujusdam meteoroscopii armillaris,' Ingolstadt, 1533, fol. (appended to an edition of Apian's 'Introduction to Geography'). 7, 'Problemata 29 Sapheæ nobilissimi instrumenti à I. de Monteregio,' Nürnb., 1534. (The Saphee bore some resemblance to the Analemma.) 8, Mahometis Albategnii de Scientia Stellarum Liber, Latinè ex Arabico per Platonem Tiburtinum versus, et additionibus aliquot Joannis Regiomontani illustratus,' Nürnb., 1537, 4to. (Niceron). 9, 'De Ponderibus et aquæductibus, cum figurantibus Instrumentorum ad eas res necessariorum,' Marpurgi, 1537, 4to. 10, 'Tabulæ Revolutionum,' 4to. n. d. 11, 'De Influentiis Stellarum,' Argentorati, 1538. 12, 'Problemata Astronomica ad Almagestum spectantia,' Nürnb. 1541 (Niceron). 13, 'Fundamenta operationum quo fiunt per tabulam generalem,' Idem., 1557, fol.

Three MSS., in Müller's handwriting, came into De Murr's possession. One consisted of notes on the Latin version of Ptolemy's Geography. The second was his defense of Theon against Trebizond. The third was entitled 'De Triangulis omnimodis Liber V. Extracts from these were published by De Murr, under the title of 'Noticia trium codicum autographorum Johannis Regiomontani,' Nürnb., 1801, 4to. Müller's Letters were also published by De Murr in 1786, in his 'Memorabilia Bibliothecarum publicarum Norimbergensium et Universitatis Altdorfianæ,' tome i., pp. 74-205. See also 'Astron. du Moyen Age,' pp. 344-65. Weidler, in his 'Historia Astronomiæ,' pp. 310-313, gives a list of the works which issued from Müller's press at Nürnberg, and also of those which he contemplated publishing.

(Montucla, *Histoire des Mathématiques*, and the works above quoted. The reader may further consult the *Life of Müller* by Gassendi, appended to his *Life of Tycho Brahé*, Paris 1654, 4to.; Fabricius, *Bibliotheca Latina Mediæ et Infimæ Latinitatis*, tom. iv., p. 353; *Pauli Jovii Elogia*, No. 144.)

REGISTER, REGISTRATION, REGISTRY. In feudal times, the owner of land, or at least the person immediately entitled to the profits arising from it, was usually the occupier, and his right was notorious among his neighbours; for in their presence possession or *seisin* of the land was delivered to him upon the spot by the lord; they signed the instrument, which was evidence of the grant, and they formed part of the lord's court, in which the grant was usually recorded. [CONVEYANCING.]

But this simple method of conveyance was in the course of time found insufficient for the more complicated circumstances of society. Land by improved cultivation became more productive, and the profits arising from it were devoted to more extensive purposes than when a large proportion of every great estate was waste. Leases of land then became more common, and as the lessee was of course in actual possession of the premises, possession ceased to be sufficient evidence of absolute property in land. Purchasers therefore now require not only proof of possession and production of the instrument by virtue of which the apparent proprietor holds the land, but also an investigation of the *title-deeds*, or documents which form the history of the land; lest any one should hereafter be produced which should be destructive of the claim of the supposed owner, and therefore of the title of those who derive their rights from him. Thus the evidence of a right to land, or to the profits arising from land, consists partly of possession, partly of the facts disclosed by the written documents or *title-deeds* relating to it, and hence partly again of the possession of the title-deeds themselves.

But there are many interests in land which exist without either of these protections. For instance, A, who is supposed by all his neighbours to be the owner of an estate which he derives from his ancestors, and has occupied since his father's death, mortgages the land to B for a sum far less than its value: he delivers the title-deeds to B, but (as is usual) retains the possession and entire enjoyment of the land by paying regularly the interest on the mortgage, and being supposed well able to pay the principal money when demanded. A then mortgages the estate a second time to C, to whom he gives notice of the prior incumbrance to B, and thus accounts for the absence of the title-deeds, which C investigates in B's hands. Here we observe that C has an interest in the land, without the security which either possession or the holding of the title-deeds gives A has the one, B the other. We will suppose the two sums for which the estate is mortgaged to be nearly equal to its value. A borrows a further sum upon it from D, whom he informs of B's mortgage, but not of C's; and in case of dispute the Court of Chancery has to decide between the mortgagees. This would be an easy task if the rule of equity were undeviating, that priority of time gives superior right (qui prior est tempore potior est jure); but the rule that where equities are equal, law shall prevail, destroys the simpler maxim. The two last mortgagees, C and D, have, we may suppose, only an equitable interest in the land, A having granted it at the time of the first mortgage to a trustee for many hundred years, in order that the stipulations of the mortgage-deed shall be fulfilled. [MORTGAGE.] This is called creating a term of years, and it has the effect of protecting the estate from any acts done subsequently to the creation of the term, and inconsistent with the objects for which it exists. Those terms which have not merged or otherwise ceased are called *outstanding terms*. Now if, in the case supposed, D pays off B, and takes an assignment of his mortgage and of the outstanding term; if, to use the technical phrase, he 'tacks' B's security to his own, he unites in himself equal equity with C, and also the legal right which the term gives him; and then he takes precedence of C, who loses the sum which he had advanced, unless indeed he too can find and obtain the assignment of an outstanding term created by one of A's ancestors antecedently to B's. But the case may be more complicated, and the means of fraud still further extended. A dies; and then comes to light a settlement made by his father, to which A was himself a party, which shows that A was entitled to the estate only during his life, that the course in which it should go after his death had been clearly defined, and that it had been conveyed, by his father and himself, to trustees for this purpose. This discovery destroys the estates of B, C, and D alike. These cases, or cases partaking of the character of these, whether the result of ignorance, or accident, or fraud, are frequent sources of litigation: they arise from the facility afforded for the concealment of deeds by the present system of conveying land; and besides the direct injury which they do to the individuals involved in them, they produce a feeling of insecurity concerning the titles to land, which, joined to the difficulty, often the impossibility, of proving titles, especially by descent, renders the alienation of land or the raising of money upon it difficult and costly. Again the advantage derived from obtaining an assignment of outstanding terms causes a conveyancer to investigate the various transfers and transmissions of them with as much care as the title to the fee; and as it may be safest to obtain the assignment of as many outstanding terms as can be procured, and especially of the most antient, there are a variety of claims to an interest in an estate, all to be proved by the seller, and investigated by the purchaser. The deed too assigning the term is usually distinct from the conveyance of the fee, and is often of great length. Hence vast additional expense is incurred in the sale and mortgaging of land.

But supposing it to be certain that no concealed charge affects land, it may happen that the undoubted owner of it may be unable to prove his right from want of the title-deeds. N possesses an estate, which may be a small part of a much larger estate, of which the owner, M, retains the title-deeds, giving to N authenticated or *attested copies* of them, and a covenant that he, M, when required, will produce the originals. But M sells the estate, and the title-deeds pass into hands not bound by the *covenant to produce;* or he dies, and his representatives are unknown; or again, N himself sells his portion of the estate, and he cannot transfer the benefit of his covenant [COVENANT]; or, by a multitude of accidents, the deeds or some of them are lost. In these cases the estate is unmarketable. Indeed instances have been known where the mere expense of giving attested copies of deeds, which a person who had contracted to sell an estate was bound to furnish, has exceeded the value of the estate.

The Real Property Commissioners have expressed their opinion that a large proportion of all the land in the country is unmarketable, either from the fear of latent incumbrances, or from the inability of the owner to produce his title deeds. Prior incumbrances are indeed somewhat assisted by the doctrine of courts of equity, that if a subsequent purchaser or mortgagee has notice of the previous charge before his own transaction with the estate, he shall not by any device obtain priority over that charge. But notice does not necessarily imply knowledge. [NOTICE.] Notice may be an actual direct intimation of a fact given to the party or his agents, which is called *actual notice;* or it may be only something leading a discreet person to an investigation, which would enable him to discover the fact: thus the existence of a suit (lis pendens) touching the land affects the purchaser or mortgagee with notice. This latter class of notice is called *constructive;* it is so vague as to be easy of proof, and difficult to avoid; and one consequence of the admission of it in a court of equity is, that solicitors often think it their duty to avoid investigations which might lead to constructive notice, and so endanger the priority of their client's security.

These remarks may assist the unprofessional reader in understanding the use of a general register of deeds, a subject which the Real Property Commissioners declare to exceed in importance all others submitted to their inquiry. To this subject they have devoted their Second Report, and they unanimously recommend the establishment of a General Public Register for England and Wales of all deeds or instruments affecting land, in order to secure titles against the loss or destruction, or the fraudulent suppression or accidental non-production of instruments; to simplify titles by rendering in most cases needless the assignment of outstanding terms; to protect them from the consequences of constructive notice; and to render conveyances shorter and more simple.

To a certain extent such registers have been already established in England. By the 27 Henry VIII., c. 16, it is enacted that all bargains and sales of land shall be inrolled. [BARGAIN AND SALE.] The 2 & 3 Anne, c. 4 (amended by 5 Anne, c. 18) directs that a memorial of all deeds, conveyances, and wills concerning any lands in the West Riding of Yorkshire may, at the election of the parties, be registered; and that any conveyance or will affecting the same lands shall be deemed void against a subsequent conveyance unless a memorial shall be registered. The 6 Anne, c. 35, recites that 'lands in the East Riding of York, and in the town and county of the town of Kingston-upon-Hull, are generally freehold, which may be so secretly transferred or conveyed from one person to another, that such as are ill disposed have it in their power to commit frauds, and frequently do so, by means whereof several persons (who, through many years' industry in their trades and employments, and by great frugality, have been enabled to purchase lands, or to lend moneys on land security) have been undone in their purchases and mortgages by prior and secret conveyances and fraudulent incumbrances; and not only themselves, but their whole families thereby utterly ruined:' and then the act establishes a register of the memorials of deeds and wills in the East Riding of Yorkshire. The 7 Anne, c. 20, establishes such a register for Middlesex; and the 8 George II., c. 6, establishes one for the North Riding of Yorkshire, and provides that deeds, wills, and judgments affecting land may be registered at length, instead of the registration of mere memorials of them. In the Bedford Level too there is a registration of all deeds affecting land there. These registers, owing to the insufficiency of their indexes, and to some other defects, do not answer all the purposes which might be expected from them, and in many respects their arrangements are cumbrous and expensive: nevertheless (as the Commissioners remark) no one has proposed to abolish them. A registration of wills has long been established in the ecclesiastical courts [PREROGATIVE COURT], not certainly upon a good pla since it is not always possible to say beforehand in wh court a will has been proved, but nevertheless with gre advantage. The recent act for Abolishing Fines and Recoveries (3 & 4 Wm. IV., c. 74) substitutes for them a de which is inrolled in the Court of Chancery. In Ireland, the Colonies, in most of the United States, in Swed France, and Italy, and in many of the German States, reg ters are established. Nor is it found that the disclosu which a register makes of the state of landholders' prop produce inconvenience, even supposing such disclosure separable (which they are not) from all systems of regis tion. It is obviously for the public benefit that the appar extent of a person's landed property should not induce to give him a credit to which the actual amount of that perty does not entitle him.

As the plan of register proposed by the commissioners not yet been adopted, it will be only necessary briefly to dicate its main provisions. They propose to register e document transferring any estate in land or charge up excepting such as relate to copyholds, and leases for more than twenty-one years, accompanied by poss Thus contracts concerning land (with certain limitat liens upon it, judgments, crown debts, decrees in eq pending suits and appeals, should all form matters registration. They recommend that all deeds should registered at length; indeed that the original deeds sh be deposited at the Registry, and that (unless in spe circumstances) office-copies of them shall be adm as evidence. They propose that the register should be classified according to the names of individuals, that to the registered deed relating to an estate a sym shall be attached indicative of that estate, under wh symbol all subsequent documents affecting it will be e tered. The system admits of opening a fresh series entries, or, in other words, commencing a new title for an portion of the estate which may be separately convey re ferences being made from each to the other. And again many separate estates might be united under symbol. Indexes should be prepared both of the sym and of persons: and to facilitate reference, England Wales should be divided into districts, usually corres ing in limits with the counties. Separate indexes shou made to wills, judgments, &c.

It is the opinion of the commissioners that if a regi established, it ought to be taken as sufficient notice of documents registered; and that on the other hand default of registration ought not to be remedied by any proof even of actual notice. With this view they recommend that persons should have liberty to register contracts, to enter caveats during the interval between the execution of the deed and its registration, and inhibitions which shall prevent owners of estates who enter them from dealing with the estate pending such inhibition.

The act 1 and 2 Victoria, c. 110 (abolishing arrest on mesne process, except in certain cases) provides (§ 19) that no judgment of the superior courts or decree of the courts of equity shall affect lands unless a memorandum of such judgment, &c. shall be registered with the senior master of the Court of Common Pleas, who shall enter it under the name of the person whose estate is to be affected by it. The 2 and 3 Vic., c. 11, enacts that these registered judgments shall not be valid for a longer space than five years, but it provides that the entry of them may be renewed; it also enacts that no pending suit (lis pendens) shall affect the purchaser or mortgagee with notice, unless a similar memorandum is registered by the same officer, under the head of the person whose estate is affected by it, and the entry must be renewed every five years; and thirdly the act requires crown debtors to be registered in the same office, and provides means for obtaining and recording their discharge from their liabilities to the crown; but the act does not require the renewal every five years of the entry in this case.

REGISTER ACT. [SHIPPING.]

RE'GIUS MORBUS, as used by the classical Latin authors, must not be confounded with the *King's Evil*, or *Regius Morbus*, of the writers of the middle ages. In the former it means jaundice (Horat., *Art. Poet.*, 453), called also ἴκτερος, 'morbus arquatus,' and 'aurugo' (or 'aurigo'); in the latter it means scrofula. [SCROFULA.] The derivation of the term as applied to jaundice is both uncertain and unsatisfactory. According to Serenus Samonicus (*De Medic.*, cap. 58, v. 1033)—

'*Regius* est vero signatus nomine morbus,
Molliter hic quoniam celsa curatur in aula.

Varro (apud Plin., *Hist. Nat.*, lib. xxii., cap. 53, ed. Tauchn.), '*Regium* cognominatum morbum arquatum tradit, quoniam mulso curatur;' 'Scilicet,' (says Doering ad Horat., *loc. cit.*), '*mulsum* (vinum melle conditum) pertinet ad delicias, quas reges imprimis et beatiores appetunt et facile sibi comparare possunt.' The same derivation is given by Celsus (*De Medic.*, lib. iii., cap. 24), who says the cure is to be attempted by various kinds of exercises: 'Lecto etiam et conclavi cultiore, lusu, joco, ludis, lascivia, per quæ mens exhilaretur, ob quæ *regius* morbus dictus videtur.' Blancardus (*Blanckaert*, or *Blankaard*) in his 'Lexicon Medicum,' is rather inclined, 'ab *auro*, metallorum *rege*, denominationem statuere, sicut et *Aurigo*, ab *auri* colore.' Dr. Good (*Study of Medicine*) says, 'the meaning of *Regius*, as expounded by Celsus, will, I apprehend, content very few;' he then remarks that this and the two other Latin names of the disease (*Arquatus Morbus*, and *Aurugo*) 'are not indeed univocals, but very nearly equivalents, and equally import *gold, golden crown, golden bow,* or *circumfusion*; the colour of the disease, and its encompassing the body.' Each of these derivations appears somewhat far-fetched and unsatisfactory, and the term is probably one of those of which no plausible explanation can be given.

REGRATING. A regrator is defined (6 Ed. VI., c. 14) to be one who buys in a fair or market the various articles specified by the act; which are principally articles of provision, and sells them again in the same, or in any other fair or market within four miles. That statute and others providing certain penalties for such acts have all been repealed by 12 Geo. III., c. 7. Whether or not regrating is an offence at common law is doubtful; and at all events to make it so the act must be done with intent to raise the price of provisions. (Burn's *Justice*, tit. 'Forestalling.')

REGULAR CLERGY. [CLERGY.]

REGULAR FIGURES, POLYGONS, SOLIDS, POLYHEDRONS. We have here to add to what is said in POLYGON AND POLYHEDRON all that concerns the regular figures or solids, not as to their general properties, but as to the proportions of their parts and the mode of describing them. We shall take first the plane figures, and then the solids.

A regular polygon, meaning one of which all the sides are equal and all the angles are equal, may have any number of sides from three upwards. The Greek terms trigon, tetragon, pentagon, hexagon, heptagon, octagon, nonagon, decagon, undecagon, dodecagon, are in use (except the two first) to express polygons of three, four, &c., up to twelve sides. The term quindecagon is in use to express the polygon of fifteen sides.

Let the polygon be described, having n sides: let its side be a, its area V, and let r and R be the radii of the inscribed and circumscribed circles. The formulæ which connect these quantities are then as follows:—Let ν stand for the nth part of 180°, then

$$a = 2\,\mathrm{R}\sin\nu = 2r\tan\nu,$$

$$\mathrm{V} = \frac{na^2\cot\nu}{4}$$

which are enough to determine the remaining three of V, a, R, r, when one of them is given. To facilitate the determination and construction of any regular polygon not having more than twelve sides, we take the following table from James Dodson's 'Calculator' (1747), which is correct to every figure as far as we have thought it necessary to examine it. The author generally corrected errata with his own pen in every copy, and the one before us has his corrections:—

When the Length of Side = 1.

No. of Sides.	Radius of Circumscribed.	Radius of Inscribed.	Area.
3	0·5773503	0·2886751	0·4330127

12	0·2988585	0·5773503	0·5576775

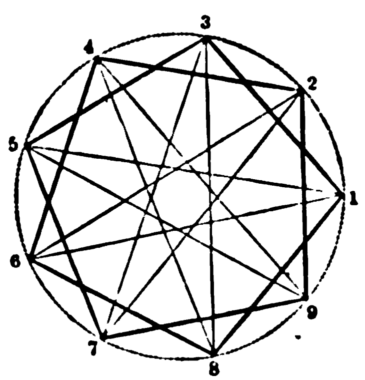
By means of these tables the construction of any figure is immediately reduced to a short calculation, the drawing of a circle, and setting off equal chords on that circle, the compasses and a scale of equal parts being all the instrumental aid necessary. It is required to construct, for example, a regular heptagon, or figure of seven sides, with an area of 225 times the square on one of the larger divisions of the scale. The side and radii must therefore be increased in the fourth table in the proportion of $\sqrt{225}$ to $\sqrt{1}$, or of 15 to 1. And

$$\cdot5245813\times15=7\cdot8687 \text{ side.}$$
$$\cdot6045183\times15=9\cdot0678 \text{ rad. circum.}$$
$$\cdot5446520\times15=8\cdot1698 \text{ rad. inscr.}$$

If the two circles be carefully drawn from the same centre, and chords equal to the side taken off, the compasses will be found to be carried exactly seven times upon the larger circle, and the chords, being drawn, will be found to touch the inner circle. and any little error of construction will be better shown by failure of touching the inner circle correctly than by any other means.

The above presumes that it is desired to proceed as accurately as possible; but for rough work, and when the circumscribed circle is known, the proportional compasses, or even a common pair of compasses and trial, will succeed perfectly well. The proportional compasses have a scale for the adjustment of the pivot in such manner that when the opening at one end is the radius of a circle, that at the other end shall be the side of the inscribed polygon of a given number of sides.

The regular polygons hitherto treated have been those of Euclid, without any re-entering angles. The star-shaped polygons (which, though equilateral and equiangular, do not come within Euclid's definition) are described by drawing a regular polygon of the same number of sides, and drawing successive diagonals so as to cut off a number of sides which is prime to the number of sides of the polygon.



Thus if 12, 23, 34, &c. be the sides of a regular nonagon, or nine-sided polygon, it follows that there are two regular star-shaped nonagons, one made by diagonals which cut off 2 or 7 sides, and one made by diagonals cutting off 4 or 5 sides. Diagonals cutting off three sides would give three equilateral triangles, but no nonagon at all. These nonagons are 1357924681, and 1594837261. Star-shaped dodecagons are also only one in number, since 5 and 7 are (except 1 and 11, which would only give the dodecagon of Euclid) the only numbers less than 12 which are prime to 12. But a regular polygon of 13 sides has 5 star-shaped polygons, made by diagonals cutting off 2 and 11, or 3 and 10, or 4 and 9, or 5 and 8, or 6 and 7 sides.

We now come to the subject of regular polyhedrons, presuming the reader to know the contents of the article POLYGON AND POLYHEDRON. A great many properties of these solids have been investigated, but as they are of little use, it will be unnecessary to do more than show the relations of their parts, the radii of the inscribed and circumscribed spheres, and the solidities and surfaces: with tables for constructing them of given dimensions. Let a solid be contained by f faces, each of which is a regular polygon of n sides. Let c be the number of corners or solid angles, e the number of edges, and m the number of angles which meet at a corner. Then since there are c corners with m angles at each, the number of edges, counting each edge as often as it meets a corner, is mc; or, as each edge meets a corner twice, $\frac{1}{2}mc=e$, the number of distinct edges. Again, since there are f faces, of n sides each, and every edge is the union of two faces, we have $\frac{1}{2}nf=e$. But $f+c=e+2$, or

$$\frac{2e}{n}+\frac{2e}{m}=e+2, \text{ or } e=\frac{2mn}{2m+2n-mn}$$

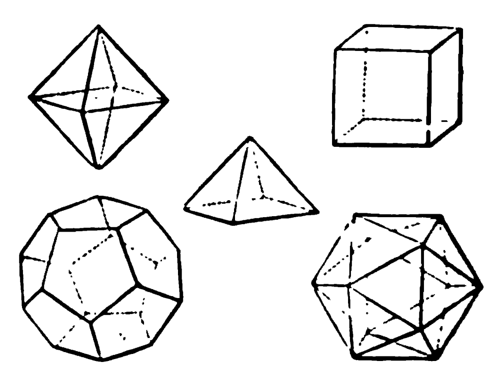
which must be a whole number. And neither m nor n can be less than 3, nor greater than 5, for there are no figures of fewer sides than 3, and [POLYGON AND POLYHEDRON] spaces cannot be inclosed entirely by figures of more than five sides. The rest follows from the properties of conjugate solids in the same article.

Let $n=3$, or $e=6m\div(6-m)$. This is a whole number (1) when $m=2$; this must be rejected: (2) when $m=3$, giving $n=3$, $m=3$, $e=6$, $f=4$, $c=4$, or four triangles; we have here the regular tetrahedron, or triangular pyramid: (3) when $m=4$, giving $n=3$, $m=4$, $e=12$, $f=8$, $c=6$, or eight triangles; we have here the regular octohedron: (4) when $m=5$, giving $n=3$, $m=5$, $e=30$, $f=20$, $c=12$, or 20 triangles; we have here the regular icosahedron.

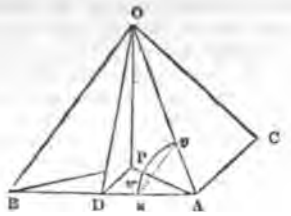
Let $n=4$, or $e=8m\div(8-2m)$. This is a whole number (1) when $m=2$; which reject: (2) when $m=3$, giving $n=4$, $m=3$, $e=12$, $f=6$, $c=8$, or six squares; we have here the regular hexahedron, or cube, the only one of its kind.

Let $n=5$, or $e=10m\div(10-3m)$. This is a whole number (1) when $m=2$; which reject: (2) when $m=3$, giving $n=5$, $m=3$, $e=30$, $f=12$, $c=20$, or 12 pentagons, we have here the regular dodecahedron, the only one of its kind.

We have thus the five regular solids, and have shown that there can be no others.



The centre of a regular polyhedron is obviously the point of intersection of lines drawn from the corners, each inclined at the same angle to all the edges which meet it. The radius of the circumscribed sphere (R) is the line drawn from any corner to the centre; that of the inscribed sphere (r) is the perpendicular let fall from the centre upon any of the faces. Let O be the centre, A any corner, AB and AC adjacent sides of one of the faces passing through A, and let OP be the perpendicular. Let a be the side of the polygon, $2x$ the angle BOA subtended by any edge BA, and y the angle made with OP by the line OD bisecting BOA.



Let $\frac{180°}{n}=\nu,\ \frac{180°}{m}=\mu.$

Now $DPA=\frac{1}{2}\frac{360°}{n}=\nu.$

The angle of the planes DAO, OAP, is half of an angle m of which meeting at A make four right angles, it is therefore $360°\div 2m$, or μ. And drawing the right angled spherical triangle which represents the solid angle AD, AP, AO, we see that its angle at v is μ, the side wu is $90°-\nu$, and the hypothenuse vu is $90°-x$. Hence

$$\sin(90°-\nu)=\sin(90°-x)\,;\ \sin\mu \text{ or } \cos x=\frac{\cos\nu}{\sin\mu}$$

But the angle at u is $90°-y$, whence

$$\cos\mu=\cos(90°-\nu)\sin(90°-y);\ \text{or}\ \cos y=\frac{\cos\mu}{\sin\nu}.$$

The determination of x and y, angles depending only on the number of sides of the polygon and the number of angles which meet at each corner, settles every question. We have

$$a=2R\sin x \quad \ldots\ldots (1)$$

$$r=OD\cos y=R\cos x\cos y=R\cot\nu\cot\mu \ldots (2).$$

The superficies (S) of the solid is f times the superficies of one face, or

$$S=f.\frac{na^2\cot\nu}{4}=nfR^2\sin^2 x.\cot\nu \ldots (3).$$

The solidity or volume (V) is the superficies multiplied by the third part of r, or

$$V=\tfrac{1}{3}nfR^3\sin^3 x.\cot^2\nu.\cot\mu \quad \ldots (4).$$

The angle of two faces with a common edge is $180°-2y$. We also see that in conjugate solids [POLYGON AND POLYHEDRON] the angles x and y are inverted, the value of x in one being that of y in the other, and *vice versâ*.

The following are the values of μ and ν in the several solids:—

Tetrahedron $\mu=60°,\ \nu=60°\ \cos\mu=\cos\nu=\frac{1}{2}$.

Hexahedron $\mu=60°,\ \nu=45°\ \cos\nu=\frac{1}{2}\sqrt{2}$.

Octohedron $\mu=45°,\ \nu=60°$.

Dodecahedron $\mu=60°,\ \nu=36°\ \sin\nu=\frac{1}{2\sqrt{2}}\sqrt{(5-\sqrt{5})}$.

Icosahedron $\mu=36°,\ \nu=60°$.

These formulæ will enable any one to verify the various expressions with which old books of geometry abound. The following table answers to that for polygons, and is taken from the same source:—

When the Side = 1.

Solid.	Radius circumscribed.	Radius inscribed.	Superficies.	Volume.
Tetrahedron .	0·6123724	0·2041241	1·7320508	0·1178511

REGULUS, M. ATILIUS. [PUNIC WARS.]

RE'GULUS. [SYLVIADÆ.]

RE'GULUS. A line drawn from the pole star, not through the two pointers, but between them and the five secondary stars of the Great Bear, which lie near them, will pass through the bright star called α Leonis, or Cor Leonis (the lion's heart). By Ptolemy and other Greeks it was called *βασιλίσκος*, whence comes the Latin name Regulus, a word which is the diminutive of *rex*.

REICHA, ANTOINE, a well-known composer, though more esteemed as a writer on music, was born at Prague in 1770, but educated at Bonn under his uncle, where he at first clandestinely studied the art passionately loved by him, and which soon became his profession; from which acknowledgment, made by himself, it is to be presumed that he was originally intended for a different pursuit. He early attempted musical composition, and when only seventeen years of age conducted the performance of his first symphony. In 1794 he went to Hamburg, and there remained five years, applying much to the abstruse theory of music, for which study his knowledge of algebra, a branch of mathematics wherein he was highly skilled, eminently qualified him. At the same time he also devoted great attention to the French language, in which he composed an opera in two acts. In 1799 he proceeded to Paris, and at the celebrated concert *de Cléry* produced with decided success a grand symphony. He afterwards took up his residence at Vienna, where he wrote many of his works, and among them thirty-six fugues for the piano-forte, the whole edition of which was sold in the first year. He returned to Paris in 1808, and there remained till his decease, which took place in 1836.

M. Reicha was a member of the Institute in both its forms, and a very leading professor of composition at the *Ecole Royale de Musique*. Among his numerous works, those on which his future fame will rest are, *Cours de Composition, ou Traité complet et raisonné d'Harmonie Pratique*, in 1 vol. folio; and *Traité de Mélodie, Abstraction faite de ses Rapports avec l'Harmonie*, in 2 vols. 4to., 1814, both of which ought to be carefully studied by every musician who wishes to understand his art otherwise than empirically.

REICHENBACH, now the chief town of a circle in the government of Breslau in Silesia, was the capital of a government of the same name, which was abolished and annexed to the government of Breslau by a cabinet order of the 3rd of February, 1820. It is surrounded by a double wall and moat, and has four gates and four suburbs. There are a Roman Catholic and a Protestant church, a Catholic and 2 Protestant schools, a synagogue, and a drawing-school for mechanics. The inhabitants, nearly 5000 in number, manufacture linen, woollen, cotton, canvas, muslin, &c. This town is remarkable for the action fought in its vicinity on the 16th of August, 1762, in which the duke of Brunswick-Bevern defeated the Austrians under Marshal Daun, who was coming to the relief of Schweidnitz; and for the convention concluded in 1790 by the ambassadors of England, Holland, Poland, Prussia, and Austria, by which the further existence of the Turkish empire was secured, which Austria and Russia wished to destroy.

REICHENBERG, the largest and most flourishing town in the kingdom of Bohemia next to Prague, is situated in the north part of that kingdom, in the circle of Bunzlau, on the river Neisse, 52 miles north-north-east of Prague. It is the capital of a lordship belonging to Count Claus-Gallas, which contains thirty-seven other places, some of which are considerable. The principal buildings are, three churches, two palaces, a theatre, and the handsomest and largest school-house in all Bohemia. There are four great manufactories of woollen cloth, with fulling-mills and dyeing-houses. There are besides manufactories of stockings, hats, linen, and calico. The annual value of the goods manufactured here is above half a million sterling. The trade of the town is very considerable, it being the staple place for all woollen, linen, and cotton manufactures of the circle. The population is nearly 15,000.

On the 21st of April, 1757, a victory was gained near this town by the Prussians under the duke of Brunswick-Bevern, over the Austrians.

REICHENHALL, a town in the circle of the Isar in Bavaria, is situated in a romantic country on the left bank of the Saale, at an elevation of 1323 feet above the level of the sea. Though it has not 3000 inhabitants, it is a place of great importance, as being the central point of the four great salt-works of Bavaria, which are connected by an immense system of pipes and conduits, by which Traunstein and Rosenheim are provided with brine from this place, and the brine of the salt-springs at Berchtesgaden is brought to Reichenhall, either to be boiled with the brine of the springs there, or conveyed to Traunstein or Rosenheim. Almost all the manufactures of machinery, which furnish everything requisite for the salt-works, are at Reichenhall. The most antient documents relative to the salt-springs at Reichenhall are of the eighth century. As the great consumption of wood for so many years made fuel too scarce to boil all the brine on the spot, a very ingenious system of pipes was contrived in 1618 from Reichenhall to Traunstein, over an elevation of 828 feet perpendicular height, and extending eight leagues in length. A similar conduit to Rosenheim on the Inn, where there is abundance of wood, was made in 1809, by M. Reichenbach. It is fourteen leagues in length; so that now all the springs which formerly ran to waste for want of wood are turned to account. In 1817, M. Reichenbach, with very great skill, connected the salt-springs of Reichenhall, Traunstein, and Rosenheim with the salt-mines of Berchtesgaden. Though the Ferdinandsberg at Berchtesgaden is only 160 feet higher than Reichenhall, yet, on account of the intervening mountain-chain between the two places, it was necessary to raise the brine by waterworks to the height of 1579 feet, and so let it have a fall of 1740 feet to Reichenhall. For this purpose a conduit, partly covered, partly open, of 102,000 feet in length, part iron, part wood, was required. The machine erected at Illsang on a new principle by M. Reichenbach, raises the saturated brine to an elevation of 1218 feet perpendicular. The quantity of salt produced annually is 16,000 tons.

REID, DR. THOMAS, was born April 26th, 1710, at Strachan in Kincardineshire, about twenty miles from Aberdeen, of which parish his father, the Rev. Lewis Reid, was minister for fifty years. He was first sent to the parish school of Kincardine, and after two years he was removed to Aberdeen to be placed under a course of preparation for the university. At the age of twelve or thirteen he entered the Marischal College of Aberdeen. The principles of the philosophy of which he afterwards became so able an advocate he imbibed here under Dr. George Turnbull, author of 'The Principles of Moral Philosophy.' He continued beyond the usual time at the university, of which he had been appointed librarian. This office he resigned in 1736, and he then visited England in company with Dr. John Stewart, afterwards professor of mathematics in the Marischal College. They proceeded to London, Oxford, and Cambridge, and were introduced to several distinguished men, among whom were Dr. Bentley and Mr. Saunderson, the blind mathematician. In 1737 Reid returned to Scotland, and was presented by King's College, Aberdeen, to the living of New Machar in Aberdeenshire. His entrance upon this living was by no means a pleasant one. The parishioners, having been accustomed to a minister of intemperate zeal, and being averse to the system of patronage which led to this appointment, were at first violently opposed to Reid; but his unwearied attention to his duties and the mildness of his temper soon overcame their opposition, and converted their dislike into the highest esteem. It appears however that he had been so little used to composition, and was naturally so diffident, that for some time he delivered very few of his own sermons, but used those of Archbishop Tillotson and Dr Evans. In 1740 he married Elizabeth, daughter of his uncle Dr. George Reid, a physician in London.

While he was minister of New Machar, he pursued a course of intense study; and in 1748 he inserted in the 'Transactions of the Royal Society of London' 'An Essay on Quantity, occasioned by a treatise in which simple and compound ratios are applied to virtue and merit.' In other words, it was an essay on the application of mathematics to morals. Doctors Pitcairne and Cheyne had recently attempted to apply mathematics to medicine, and Hutcheson to morals. According to the latter, the good done by a man depends partly on his benevolence and partly on his dispositions; the relations between these moral notions might be expressed algebraically, after this manner:—the benevolence or moral desert of an agent was analogous to a fraction, which had the good performed for the numerator, and the dispositions of the agent for the denominator. Reid, after examining in his essay the nature of mathematical proof, and the subjects to which it had been applied by Hutcheson, clearly showed that mathematics could by no means have a necessary relation to morals, because the truths to which the two sciences respectively refer addressed themselves to different faculties of the mind. In 1752 the professors of King's College, Aberdeen, elected Reid to be their professor of moral philosophy, in testimony of the high opinion which they entertained of his talents. After this appointment he devised the plan of a private literary society, which was soon formed, and which existed a long time. The society met once a week, and its object was the discussion of philosophical subjects for the mutual improvement of the members, among whom were Doctors George Gregory, Campbell, Beattie, and Gerard, including of course the projector. Though Reid had as yet published nothing but the 'Essay' mentioned above, his character as a philosopher was established; and in 1763 the university of Glasgow invited him to the chair of moral philosophy there, which was then vacant by the resignation of Dr. Adam Smith. He accepted this invitation, and entered upon his duties in 1764, in the discharge of which he laboured indefatigably to carry out his principles. In the same year he published his 'Inquiry into the Human Mind,' the substance of which he had previously delivered to his pupils at Aberdeen, and also read to the society just named. The principal object of this work was to counteract the influence of that scepticism which Hume had founded on the spiritual and ideal system of Berkeley. About the time that the 'Inquiry' was published, the author received the degree of D.D. from the university of Aberdeen. In 1773 he published, in Lord Kames's 'Sketches of the History of Man,' 'An Analysis of Aristotle's Logic,' which he wrote at the particular request of Lord Kames, who thought that no man was better acquainted with Aristotle's writings than Dr. Reid. In 1781 Dr. Reid withdrew from public labours; but he did not cease to pursue his favourite occupations. In 1785 he published his 'Essays on the Intellectual Powers,' of which the substance had been delivered, as he tells us, annually for more than twenty years to a large body of the more advanced students at Glasgow, and for several years before at Aberdeen. In 1788 came out his 'Essays on the Active Powers of the Human Mind.' Dr. Reid does not appear to have published any more works than those already mentioned; but he gave his attention to various other subjects, both in his private studies and in relation to his college lectures. Upon commencing his duties at Glasgow, he divided his course into four parts, after the example of his predecessor, Adam Smith: the first part comprised metaphysics; the second, moral philosophy; the third, natural law; and the fourth, political rights. He also gave lectures on rhetoric. He read several essays at different times before a philosophical society of which he was a member. Among these were 'An Examination of Dr. Priestley's opinion concerning Matter and Mind;' 'Observations on the Utopia of Sir Thomas More;' 'Physiological Reflections on Muscular Motion.' The last essay was read by Dr. Reid to his associates a few months only before his death, which took place October 7, 1796, in the eighty-seventh year of his age. After his death, his 'Essays on the Intellectual and Active Powers' were published by Mr. Dugald Stewart, as 'The Philosophy of Dr. Reid,' with a life of the author prefixed, from which this account of him it chiefly taken.

The moral and social qualities of Dr. Reid were such as naturally to inspire esteem, and in private life no man could be more highly esteemed than he was. As a writer, his language is simple and manly, and his style clear and forcible, without any pretence to ornament. Opinions vary as to the merits of his philosophy. His aim was to arrive at the general laws which regulate our mental operations by the inductive method, which, he thought, had never been applied to this subject. He has the merit of showing the unsatisfactory nature of certain moral systems proposed by his predecessors. Whether he has laid the foundation of a system that will prove satisfactory is very doubtful. Perhaps the laws which regulate the material world will never be found altogether applicable to the operations of mind. In all the attempts that have hitherto been made so to apply these laws, some conclusions have inevitably followed, which our sense of right and wrong refuses to admit, and this men will ever regard as a safer guide than any scheme of philosophy however ably propounded. As to Dr. Reid's view of Aristotle's logic, it appears only just to say that he did not clearly understand it. If candour and patient investigation could alone have unfolded the meaning of Aristotle, Dr. Reid would have been successful in this matter; but it is probable that he never received a good classical training, and never read Aristotle in the original with a mind free from the influence of the false interpretations of his writings which had so long prevailed. It is not to be expected that any man can understand Aristotle without thoroughly studying him in his own language.

(Stewart's *Life of Reid*; Chalmers's *Biographical Dictionary*; *Biographie Universelle*.)

REIGATE. [SURREY.]

REIMARUS, HERMANN SAMUEL, was born at Hamburg, December 22, 1694. Early in life he devoted himself to the study of languages, and he became distinguished for his knowledge of the Latin, Greek, and Hebrew. He pursued his studies at the university of Wittenberg, and upon the completion of his course, in 1717, he maintained some theses 'On the Differences of Hebrew Words,' which established his character for learning and acuteness. He then began to travel, and, having passed over several parts of Germany, he stayed a considerable time at Weimar, where he took the opportunity of publishing a collection of minor productions. After having satisfied his curiosity, he returned to Hamburg, and in 1727 he was made professor of philosophy in the university of that city, and he filled this office with much honour to himself during the space of 41 years. Reimarus married, in 1728, Johanna Frederica, the third daughter of the celebrated J. A. Fabricius. This connection with Fabricius proved to him the occasion of many and great advantages, and he also assisted Fabricius in some of his important literary labours. Towards the end of his life Reimarus devoted his hours of leisure to the study of natural history, of which he acquired an extensive knowledge. He had naturally a feeble constitution, and he was long a sufferer from ill health. He died March 1, 1768, in the 74th year of his age. Reimarus was a member of the Imperial Academy of St. Petersburg, and also of most of the literary societies in Germany. He was a man of varied and solid learning, of unwearied industry, and of great moral worth. His principal works are the following:—1, 'A Commentary on the Life and Writings of John Albert Fabricius,' Hamburg, 1737, 8vo.; 2, 'A Letter to Cardinal Quirini concerning the works of Dion Cassius,' Hamburg, 1746, 4to.; 3, 'The Roman History of Dion Cassius,' Hamburg, 1750, 2 vols. folio. In the publication of this work he availed himself of materials which had been prepared by his father-in-law, Fabricius, who had projected an edition of this author. Reimarus's edition of Dion Cassius is pronounced by Dr. Harwood 'one of the most correct and valuable Greek books ever published. 'The notes,' he adds, 'contain a treasure of erudition.' 4, 'A Dissertation on the Counsellors of the Great Sanhedrin,' Hamburg, 1751, 4to.; 5, 'A Discourse on the Principal Truths of Natural Religion,' Hamburg, 1754, 8vo.; 6, 'Observations, Physical and Moral, on the Instinct of Animals,' Hamburg, 1760, 2 vols. 12mo. He is said moreover to have written the essays which were published by Lessing, in 1774 and 1777, and known by the name of the 'Wolfenbüttel Fragments.' [RATIONALISM.]

(Weiss, in *Biographie Universelle*; Reimarus's *Life of J. A. Fabricius*.)

REIMS, or RHEIMS, a town in France, in the department of Marne, on the right or north bank of the Vêle, a feeder of the Aisne, 80 miles from Paris in a direct line east by north, or 96 miles by the road through Dammartin and Soissons, in 49° 14′ N. lat. and 4° 2′ E. long. In the Roman writers this town appears under the name of Durocortorum. It is mentioned by Cæsar, in whose time it was the capital of the Remi, one of the most considerable nations of Belgic Gaul, remarkable for their steady adherence to the alliance of Rome. Strabo writes the name Δουρικόρτορα (Duricortora). It was at the convergence of several military roads, according to the Antonine Itinerary and the Peutinger Table. At a later period it took the name of the people to whom it belonged, and is mentioned by this name (Remi) in Ammianus Marcellinus and in the Notitia. Under the Roman sway Durocortorum was the most important place in the province of Belgica Secunda; and was distinguished by its literary character. Cornelius Fronto, a rhetorician of the time of Hadrian, has compared it to Athens, an indication, making allowance for rhetorical exaggeration, of its reputation.

In 494 this city, then in the hands of the Franks, by whom it had been occupied after the defeat of Syagrius, was the scene of the baptism of Clovis and the chief lords of his court, after his victory at Tolbiac. In the civil troubles of the ninth and tenth centuries, Reims was repeatedly besieged, and twice at least taken and plundered. In 1179 it was signalized by the consecration of Philippe Auguste; all the succeeding kings of France down to Charles X. inclusive have also been consecrated here, with the exception of Henri IV. (who was consecrated at Chartres), Napoleon (who was consecrated at Paris), and Louis XVIII. (who was never consecrated at all). On the Revolution of 1830 the ceremony was abolished. Reims had become at an early period the seat of a bishop, who attained the rank of metropolitan of Belgic Gaul. In the middle ages several councils were held here. Reims was also the capital of a county, afterwards of a duchy. In 1359 it was blockaded for seven months by the English under Edward III., just previous to the treaty of Bretigny. In the campaign of 1814 it was taken (12th of March) by a corps of Russians, commanded by St. Priest, a French emigrant, and retaken next day by Napoleon, who killed 2000 of the enemy, with their commander.

The town is situated in a vast basin surrounded by chalk-hills, on which some good wines are produced. The site of the town is an oblong, extending from north-west to south-east. The antient walls which surround it are between two and three miles in extent; they are strengthened with towers, and, being planted with trees, form in summer a very agreeable public walk. They enclose within their circuit many large gardens and several spaces entirely unoccupied.

The entrance into the town is by six gates, called the gates of Mars, Ceres, Bacchus, Le Dieu Lumière or Dilimire, or Dieu Merite, Vêle or Paris, and the New Gate. There are suburbs to the gates of Ceres and Vêle. The gates of Ceres and Bacchus are supposed to indicate the sites of heathen temples which were without the walls of the Roman Durocortorum. The gate of Mars, a comparatively modern erection, has superseded a more antient one, disused since 1545, but still standing, and forming part of the circuit of the walls. It is a Roman triumphal arch of uncertain date. It has three arches; that in the centre about sixteen feet wide, those on the sides twelve or thirteen feet: all three covered with bas-reliefs, parts of which are too much defaced to be intelligible. This triumphal arch is also adorned with eight fluted Corinthian columns, of which only three are in good preservation. The gradual elevation of the soil has half buried this monument of antiquity.

The streets are wide and tolerably well laid out; they are well paved and neat, but present a dull appearance from the absence of bustle, and the grass which grows plentifully in them. The houses are for the most part built of chalk, or of boards covered with slate; some of them still present their gables to the street; and in others the upper stories project, and, being supported on wooden columns, form on the ground-floor a covered walk or gallery. The houses consist for the most part only of one story above the ground-floor. The squares are generally small and of irregular shape, except La Place Royale, a regular square, surrounded by good houses or public buildings of mingled Doric and Italian architecture, and having in its centre a well-executed statue of Louis XV. The streets are adorned with fountains supplied with water from the Vêle by the waterworks erected at his own cost by the Abbé Godinot, one of the canons of the cathedral. There is a pleasant public walk planted with trees on the west side of the town.

The most striking public building is the cathedral of Nôtre Dame, considered to be one of the finest Gothic edifices in Europe. It was commenced in the thirteenth century on the site of a more antient church, which had been destroyed by fire. The length of the nave and choir is about 480 English feet, the breadth 99 English feet, interior dimension; the length of the transept (croisée) is 160 English feet, interior dimension; the height of the building is 117 English feet. The western or principal front is surmounted by two square towers rising to the height of 267 English feet, and adorned by three large doorways, loaded with a vast number of statues, bas-reliefs, and other ornaments, many of which are of exquisite workmanship. Over the principal doorway is a fine circular window or rose of stained glass. The shafts of the flying buttresses, surmounted with statues, the rose-windows over the side-doorways, and the Angel Tower, a remarkably light bell-tower rising 59 English feet above the roof of the church at the eastern end, surmounted by a ball, and by the statue of an angel from seven to eight feet high, are all worthy of attention. The interior of the church is also very striking from the vast extent of the nave, the splendid stained-glass windows, the pavement of the choir, inlaid with marble of various colours, the antient baptismal fonts, the organ, reputed to be one of the best in France, the painting of Christ washing his disciples' feet, one of the finest works of Poussin, and the antient Roman tomb of Jovinus (a citizen of Reims, who, A.D. 366, attained to the honour of the consulship, and died in 406), formed of a single block of white marble, adorned with sculptures in relief, of tolerably good workmanship.

The church of St. Remy, the most antient in the town, is almost as large as the cathedral, but not so lofty; the principal front is of simple architecture, surmounted by two lofty spires. The interior is remarkable chiefly for the tomb of St. Remy, bishop of Reims in the fifth century, an elaborate piece of workmanship, erected in 1803, partly from the remains of the more antient one destroyed in 1793. The sacred Ampulla (Ampoule), or vessel containing the oil with which the kings of France were anointed, and reputed to contain a portion of the very oil with which St. Remy had anointed Clovis, was deposited in this church until it was destroyed in the revolutionary troubles.

The church of St. Nicaise, demolished during the revolutionary period, was by many considered the finest church in the town; it was superior in elegance to the cathedral, though inferior to it in the richness of its ornaments. There are three other churches, a town-hall, and other buildings. The town-hall, begun in 1627, but not finished till 1825, is made up of three compartments, a centre and two wings, adorned with Doric, Ionic, and Corinthian columns. Over the central building, the architecture of which is superior to that of the wings, rises a tower, having a clock, an equestrian statue of Louis XIII., and four pedestrian statues. The public library is deposited in the town-hall.

The population of Reims was estimated by Expilly to have been, at the close of the seventeenth century, 30,000; and in the middle of the eighteenth, about 27,000. At the commencement of the present century it had risen again to 30,000; in 1826 it was 34,862; in 1831, 35,971; and in 1836, 38,359. The manufactures are extensive, chiefly of woollens, or fabrics of wool combined with other materials, in which branch of industry, in and round the town, 15,000 persons are employed by about 180 master-manufacturers. It is estimated that 1,200,000 kilogrammes (about 24,000 cwt.) of wool are consumed; the yearly value of the productions of the town is estimated at above a million sterling; they include woollen cloths, kerseymeres, light stuffs for summer coats and trowsers, swanskins, camlets, merinos, Cashmere shawls, flannels, blankets, carpets, hosiery, &c. The yarn is spun partly by steam-power, partly by water, and partly by horse-power. There are also manufactures of bolting-cloth, cordage, candles, soft soap, and leather. Wax and woollen bleaching, dyeing, wool-combing, brewing, and the making of machinery, are carried on. The spiced bread and biscuits of the town are in great repute. The chief trade is in the above-named articles of manufacture, corn, flour, Champagne wines, brandy, spices, colonial produce, wool, cotton-yarn, flax, hemp, raw hides. There are four yearly fairs. The trade of the place is restricted by the want of water-carriage; there are however good roads to Paris, Châlons-sur-Marne, Mézières, St. Quentin, and other places.

The woollen manufacture of Reims owes its origin to the great minister Colbert, who was a native of the town.

Reims is the seat of an archbishopric; it has an assize court, a subordinate court of justice, a commercial tribunal, and a chamber of manufactures, arts, and trades; several fiscal government offices, a public library of 25,000 volumes and 1000 manuscripts, a high school, a secondary school of medicine, schools on the principle of mutual instruction (i. e. Lancasterian schools), a botanic garden, at which courses of instruction are given, a savings' bank (*caisse d'épargne*), a loan-office (*mont de piété*), and other institutions. There are two seminaries for the priesthood, and some nunneries; before the Revolution the town was remarkable for the number of its monastic establishments. There are four hospitals or asylums, including one for orphans. The principal hospital, the Hôtel Dieu, occupies the buildings formerly belonging to the abbey of St. Remy, in which is some carved wood-work of great delicacy. There are two establishments of baths, and a large and convenient theatre.

Among the eminent natives of Reims are Colbert, the Abbé Pluche, and Linguet, a man of letters, who perished during the Revolution.

The diocese of Reims was of early foundation; it was at first a simple bishopric, and comprehended the territory subsequently assigned to the dioceses of Laon and Châlons. St. Remy occupied the see in the time of Clovis, whom he baptised. In the eighth century the bishopric was elevated to the rank of an archbishopric: its occupiers possessed great influence, and Hincmar, who held it in the middle of the ninth century, was one of the leading personages of his time.

The archbishops claimed, and in most cases exercised, the right of officiating at the consecration of the kings of France; they had the dignity of dukes, and ranked first among the peers of France. The suffragans of the see were anciently the twelve bishops of Amiens, Arras, Beauvais, Boulogne, Cambray, Châlons, Laon, Noyon, Senlis, Soissons, Therouenne, and Tournay; but four of these were withdrawn on the elevation of Cambray (in A.D. 1559 and 1560) into an archbishopric, with Arras, Therouenne, and Tournay as its suffragans; and others were suppressed at the Revolution. At present the suffragans are the bishops of Amiens, Beauvais, Châlons, and Soissons. The diocese of Reims comprehends the town and its arrondissement.

The arrondissement of Reims has an area of 685 square miles; it comprehends 181 communes, and is divided into ten cantons. The population, in 1826, was 118,340; in 1831, 120,680; and in 1836, 123,919.

REINEKE or REINEKE FUCHS, Reynard the Fox (Reineke is probably only a corrupt diminutive of Reynard, or the French *Renard*), is a poem which, during the latter part of the middle ages and the early centuries of modern times, had an almost European reputation, for in some form or other it was known and read all over Europe.

The first complete version of the story in German verse was printed in 1498 at Lübeck, and bears the title 'Reynke de Voss.' It is written in the Frisian dialect, which is only a modification of that spoken in Lower Saxony, and it consists of four books, each of which is subdivided into chapters. The verses consist of iambics mixed with numerous spondees and anapæsts. The poem contains a lively picture of a court, in which the prince allows himself to be guided by the flattery of a deceitful and cunning favourite, who, notwithstanding all the wrongs that he inflicts upon others, is still successful to the last. The moral conveyed is this, that in the affairs of this world cunning has the advantage over justice. The king and his vassals and officers, as well as all other classes of persons, are represented, as in the fables of Æsop, under the names of such animals as are most suited to their individual characters. The king is accordingly represented under the name of Lion; his friend and favourite is the fox (Reineke), who, after having silenced, by his cunning, his hypocrisy, and lies, the charges which are brought against him by other animals, is loaded with favours and marks of honour by the king and his queen, and, accompanied by a numerous train of friends, returns to his castle Malepartus, where he relates to his family the happy issue of his dealings at court. The whole poem is a satire, but written in a truly epic style. The great number of editions which appeared in Germany after the first publication of it, and still more the numerous bad paraphrases in prose, which were sold by thousands at every fair, show the immense popularity which the story had in Germany.

The first edition is preceded by a prose introduction, in which the author of the German version calls himself Hinrek von Alkmer, and states that he translated the story from the Welsh (French) into German verse. But as no trace of this Alkmer can be found, the statement of Rollenhagen, who, in the preface to his 'Froschmaüsler,' calls Nicolas Baumann the author of 'Reynke de Voss,' has generally been adopted, though nothing certain is known of the matter. (Flögel, *Gesch. d. Komisch. Lit.*, iii., p. 28, &c.) The last and best edition of the poem was edited by Hoffmann von Fallersleben (Breslau, 1834), with an introduction, glossary, and commentary. The text is a correct reprint of the first edition. Göthe has made a most beautiful translation of 'Reineke Fuchs' into modern High-German, in hexameters (Berlin, 1794); D. W. Soltau has made another, in doggrel-verse (Berlin, 1803), a new and much improved edition of which appeared at Braunschweig, 1823. It has also been translated into Latin by Hartmann Schopper, under the title 'Opus poeticum de admirabili fallacia et astutia vulpeculæ Reinikes,' &c., Frankfort, 1574; this translation has often been reprinted. In 1706 there appeared in London a metrical English translation from the Latin of Schopper.

The German version of Reineke was, notwithstanding the statement of its author, formerly thought to be an original composition, but the subject was known for many centuries and in several countries before the German poem was printed. A Dutch edition of the story of Reineke, in prose, interspersed with occasional verses, was printed, in 1485, at Delft; it was reprinted in 1783, at Lübeck and Leipzig, under the title 'Die Historie va Reinaert de Vos.' The author of this Dutch version, which is in many respects superior to the German, and has probably served as the source from which the German poet drew his materials, calls himself Willam Matok, and also refers to a French work which had served him as his model. But even this Dutch version cannot have been the first, for Caxton (1481), in his English translation, states that he kept closely to a Dutch original. It may be inferred, from the various subsequent corrected and enlarged editions of this poem, as well as from the allusions of our early dramatists, that it gained considerable popularity in England too. The Flemish likewise possess an excellent metrical version, which was published in 1836, at Ghent, by Willems, with a very valuable introduction. The early French literature however is the richest in poems founded on the story of Reynard. Méon, in his 'Roman du Renard' (Paris, 1826), has shown that most of these poems belong to the thirteenth century, and more modern researches have proved that the story was known as early as the ninth century. The subject is one which so readily presents itself to the imagination, that it would be impossible with any probability to assign its invention to any particular time or nation. Whenever a work of fiction of commanding interest appears, unpoetical minds are always ready to seek some real history disguised under it, and this has been the case with this poem ever since its publication, until Jacob Grimm, in his 'Reinhart Fuchs' (Berlin, 1834), showed that there is no ground whatever for such a supposition. (Compare Carlyle's *Miscellanies*, vol. iii., p. 197, &c.)

REINE'SIUS, THOMAS, one of the most learned of modern physicians, was born at Gotha in Saxony, on the 13th of December, 1587. He was tolerably versed in the Greek and Latin languages at the age of twelve; and being afterwards sent to Wittemberg, the professors wished him to apply to theology. His inclination however led him to medicine: he continued his studies at Jena, and then travelled through various parts of Germany and Italy, remaining some time at Padua, for the sake of the medical lectures delivered there. On his return through Basle, he took his degree of doctor of medicine in that university, and then passed some time at Altdorf, in the hope of procuring a professorship by the interest of his relation Caspar Hoffman. He married, and, in 1617, settled in the practice of his profession at Hof in Franconia. Thence, on the invitation of the margrave of Bareith, he removed to that town, having the posts of the margrave's physician and inspector of the public schools. In 1627 he accepted the place of public physician of the town of Altenburg, in which he resided several years, and obtained the dignity of burgomaster. The elector of Saxony conferring upon him the rank of counsellor, he finally removed to Leipzig, where he died in 1667, at the age of eighty. Reinesius was a man of vast erudition, and may be reckoned almost at the head of learned physicians. 'There is scarcely anything (says Saxius) in the Greek and Latin authors, especially the antient medical writers, or in the monuments of antiquity, which he has left untouched in his epistles, observations, various readings, scholia, or disputations, either published or in manuscript.'

Bayle says of his writings in general, that 'good judges of literature have no sooner read some pages, but they place him above those philologers who have only a good memory, and rank him with critics who go beyond their reading, and know more than books have taught them. The penetration of their understanding enables them to draw consequences, and suggests conjectures which lead them to the discovery of hidden treasures. They by this means dart a light into the gloomy places of literature, and extend the limits of antient knowledge. Reinesius was one of this class of critics, and made it his chief business to find out what others had not said.' By his printed letters it would appear that he was consulted as an oracle; that he answered very learnedly whatever questions were brought to him; and that he was extremely skilled in the families of antient Rome, and in the study of inscriptions. A great eulogium is given of his merit, as well as of his learned and classical works, by Grævius, in the dedication of the second edition of Casaubon's Epistles, dated Amsterdam, August 31, 1655; and by Haller, who calls him (*Biblioth. Medic. Pract.*) 'a miracle of learning' (*ad miraculum doctus*); and says that 'in the accurate study and comparison of antient writers, and in sagacity in discovering the true reading of corrupt passages, he was unrivalled.' He partook of the liberality which Louis XIV. showed to the most celebrated scholars of Europe, and received at the same time a very obliging letter from Colbert, which favour he returned by dedicating to him one of his works. With respect to the character of Reinesius, his religion was suspected to be of the philosophical kind, and he seems to have no small share of the pride and irritability that too often accompany the possession of great talents and learning. This involved him in several angry controversies, and is said to have been the cause of his leaving Altenburg. He had a quarrel upon a ludicrous occasion with his friend Caspar Barthius, who, upon paying a visit to him when burgomaster, was taken by his beadle for the common hangman, and refused admission to his master. In spite of his numerous occupations and the duties of his office, he kept up a correspondence with several of the most eminent literary characters of his age, and several valuable collections of his letters have been published, viz. those to Caspar Hoffmann and Christ. Ad. Rupert, Leipzig, 1660, 4to.; to John Vorstius, Cologne, 1667, 4to.; to the elder and younger Nester, Leipzig, 1670, 4to.; to Christopher Daum, Jena, 1670, 4to.; and to John Andrew Bose, Jena, 1700, 12mo. Besides some notes on Manilius, inserted in the Strasburg edition, 1655, 4to., and some observations on Petronius, Leipzig, 1666, 8vo., one may mention the following works of Reinesius:—1, 'De Diis Syris, sive de Numinibus Commentitiis in Veteri Testamento Memoratis Syntagma,' Lips., 1623, 4to. This work, though learned, is less complete than that which Selden published afterwards on the same subject. 2, 'De Deo Endovellico ex Inscriptionibus in Villa Vizosa Lusitaniæ repertis Commentatio Parergica,' Altenb., 1637, 4to. This is a divinity of the antient Lusitanians, the same as Mars, or, according to others, Love 3, 'Ἰστορούμενα Linguæ

Punicæ Errori popu.ari, Arabicam et Punicam esse eandem, opposita,' ibid., 1637, 4to. This curious dissertation has been inserted, as well as the preceding one, by Grævius, in the 'Syntagma Variar. Dissertat. Rariorum,' Ultraj., 1702, 4to. 4, 'Variarum Lectionum Libri Tres Priores, in quibus de Scriptoribus sacris et profanis, classicis plerisque, disseritur,' ibid., 1640, 4to. These three first books were to have been followed by three others, which never appeared. It is a thick volume of about seven hundred pages, of multifarious and (as Haller says) incredible learning, chiefly, but not exclusively, classical. It also contains a good deal of matter relating to medicine, and explains several obscure and difficult passages in the antient physicians and those of the middle ages. Some of the explanations of Reinesius were attacked with much bitterness by André Rivinus, who was not ashamed of making use afterwards of all sorts of means to prevent his adversary from answering him, and even wished the magistrates to take part in a discussion entirely literary. Reinesius however succeeded in thwarting these intrigues, and published his reply under the title of 'Defensio Variarum Lectionum contra Censuram Poëtae L. (*Laureati*),' Rostoch., 1653, 4to. 5, 'Inscriptio vetus Augustæ Vindelicor. eruta et Commentario illustrata,' Lips., 1655, 4to. 6, 'Ænigmati Patavino Œdipus è Germaniâ, hoc est Marmoris Patavini Interpretatio,' ibid., 1662, 4to. This is a new explanation of the famous epitaph of Ælia Lælia Crispis, which has so much and so uselessly occupied some learned men. 7, 'De Palatio Lateranensi ejusque Comitivâ Commentatio Parergica, accedit Georg. Schubarti, de Comitibus Palatinis Cæsareis Exercitatio historica,' Jenæ, 1679, 4to. 8, 'Syntagma Inscriptionum Antiquarum,' Lips., 1682, fol. This collection only contains the inscriptions omitted, or badly explained, by Gruter. It was regretted by the learned that the editor should not have published at the same time another work of Reinesius (*Eponymologium Criticum*), which could not fail to explain a number of obscure passages in the Latin and Greek authors. The original manuscript was, in 1717, in the hands of Th. Fritsch, a bookseller at Leipzig; and it was thought that he would comply with the wishes of all philologers by having it printed (Klefeker, *Biblioth. Eruditor. Præcocium*, p. 313); but these hopes have not been realised. 9, 'Dissertatio critica de Sibyllinis Oraculis,' Jena, 1702, 4to., at the end of a work by George Schubart, 'Enarratio Parergica Metamorphoseos Ovidianæ de Diluvio Deucalionis.' 10, 'Judicium de Collectione MSS. Chemicorum Græcorum quæ extant in Biblioth. Gothanâ,' inserted in the 'Catal. Cod. MSS. Biblioth. Gothanæ,' Lips., 1714, 4to., p. 88; and in the 'Biblioth. Græca' of Fabricius, vol. xii., p. 748. To these works, which are mentioned in the 'Biographie Universelle,' and Klefeker (loco cit.), may be added, from Bayle.—11, 'De Vasis Umbilicalibus, eorumque Ruptura Observatio Singularis,' Lips., 1624, 4to. 12, 'Chymiatria, hoc est Medicina Nobili et Necessaria sui Parte, Chymia, instructa et exornata,' Geræ-Ruth., 1624, 4to. C. G. Müller lately edited his 'Observationes in Suidam,' 8vo., Lips., 1819. Another work appeared under his name, which was in fact the production of Fortunatus Fidelis, entitled 'Schola Jurisconsultorum Medica, Relationum aliquot Libris comprehensa, quibus Principia Medicinæ in Jus transumpta ex professo examinantur,' Lips., 1676, 8vo. Several other works have also been wrongly attributed to him. Some letters of Reinesius are to be found at the end of his eulogium, in the 'Elogia Clarorum Altenburgensium,' by Fred. Gotth. Gotter, Jena, 1713, 8vo. Bayle, in his 'Dictionnaire,' and Niceron, in vol. xxx. of his 'Memoirs,' have given an interesting account of him. His Life, written by himself in German, and found among his manuscripts, has been made use of in the account given by Witten, 'Memor. Philosoph.,' dec. viii., p. 461, &c. J. Brucker has inserted a more detailed life, in German, in his 'Ehrentempel der deutscher Gelehrsamkeit,' dec. iii., p. 110, Augsburg, 1747, 4to.

REINDEER. [DEER, vol. viii., p. 354.]

REINHOLD, ERASMUS, was born October 21, 1511, at Saalfeld, about sixty miles south-west from Leipzig. He taught astronomy and mathematics in the university of Wittenberg till the year 1552, when, being obliged to quit that city on account of the plague, he returned to his native province of Thüringen, where he died February 19, 1553. His published works are:—1, 'Commentary on the Theoricæ novæ Planetarum G. Purbachii,' 1542 and 1558, 8vo. This work, observes Delambre, supplied in some respect the omissions of Purbach, and must have facilitated the understanding of several passages of the Syntaxis of Ptolemy. In the dedication Reinhold shows himself so infatuated with judicial astrology as to be at the trouble of collecting all the instances which appeared confirmatory of the notion that solar eclipses were the harbingers of great calamities. 2, The first book of the Almagest, in Greek, with a Latin version and scholia, 1549, 8vo. 3, 'Prutenicæ Tabulæ Cœlestium Motuum,' 1551, 1571, and 1585, 4to. These tables were formed from the observations of Copernicus, compared with those of Hipparchus and Ptolemy. Reinhold had made some observations himself, but his best instrument was a wooden quadrant, and Tycho, on visiting Wittenberg in 1575, expressed his surprise that so celebrated an astronomer should have been provided with no better tools. In this work the author gives a very clear explanation of the equation of time. He assigns three reasons to account for astronomical tables, constructed at one period, not according with more recent observations, namely, the motion of the apogee, the variation of the excentricity, and the inequality of the precession. The last was sensible only in the systems of Thébith and Copernicus. The excentricity of the sun he makes from 0·0417 to 0·03219, and the mean precession 50″ 12‴ 5⁗ 8'''''. From a comparison of the observations of Ptolemy and Copernicus, he makes the length of the year 365d. 5h. 55m. 58s., and this determination was employed in the Gregorian reformation of the calendar. He computes the motion of the planets both after the manner of Ptolemy and that of Copernicus, whence Bailly concludes that he had no decided preference for either system. 'This conclusion,' observes Delambre, 'appears to me hazarded. The most that can be inferred is that the partisans of the antient system were yet the more numerous, and that Reinhold sought to conciliate all parties. He says nothing which can lead the reader to suspect the existence of two different systems. He neither speaks of the motion of the earth nor of that of the sun. His tables resemble our own, which still give the motions of the sun, notwithstanding that we are all Copernicans. It cannot be supposed that he who wrote a commentary on the work "De Revolutionibus," &c., who repeated all the calculations and reconstructed the tables of Copernicus, had not a sentiment of preference for a system which he had studied more than any one of his day.' The Prutenic tables were the result of seven years' labour, and where so called in compliment to the author's benefactor, Albert, marquis of Brandenburg and duke of Prussia. The 'privilege,' printed at the head of the work, which bears the date July 24, 1549, refers to several other compositions which the author contemplated publishing, such as ephemerides, tables of the rising and setting of the stars for various epochs and latitudes, &c. 4, 'Primus Liber Tabularum Directionum discentibus prima elementa Astronomiæ, necessarius et utilissimus. His insertus est Canon Fæcundus ad singula scrupula quadrantis propagatus. Item nova Tabula Climatum et Parallelorum, item Umbrarum. Appendix Canonum secundi libri Directionum qui in Regiomontani Opere desiderantur,' Tübingen, 1554, 4to. In this work the table of tangents was first extended to each minute of the quadrant from 0° to 89°, and to every 10″ from 89° to 90°. The last figure of the tangents here given can nowhere be depended on, and above 70° the error is much greater. Like Müller, he showed himself very little acquainted with the use to which such a table is applicable, notwithstanding the epithet 'fæcundus' which they applied to it. Reinhold supposed, with Copernicus, that the obliquity of the ecliptic varied from 23° 28′ to 23° 52′. 5, 'Tabulæ Ascensionum Obliquarum à 60° Gradu Elevationis Poli usque ad Finem Quadrantis, per Erasmum Reinholdum supputatæ,' appended to the edition of Müller's 'Tables of Directions,' printed in 1584. 6, There is also an anonymous work, printed in 1568, 8vo., entitled 'Hypotyposes Orbium Cœlestium quas vulgo vocant Theoricas Planetarum Congruentes cum Tabulis Astronomicis,' which is supposed to be the composition of Reinhold. See *Astron. Moderne*, i., pp. 142 and 146.

(*Astronomie du Moyen Age*, pp. 272-4; *Astron. Moderne*, i., p. 164; Zedler, *Grosses Universal Lexicon*, Leip., 17–, fol., band 31, p. 206; Vossius, *De Scientiis Mathematicis*, c. 36, p. 14; Dappelmayer, *De Mathem.*, &c.)

REINHOLD, ERASMUS, son of the preceding. He possessed some knowledge of astronomy, and submitted to Tycho a copy of the Prutenic Tables calculated to each ...

but the want of fortune obliged him to adopt the medical profession.

REISKE, JOHANN JACOB, a physician, and celebrated scholar, whose fame rests chiefly on his knowledge of Arabic, was born on the 25th of December, 1716, at Zorbig, a small town near Leipzig. His grandfather was an innkeeper, and his father a tanner. At the age of twelve he was sent to the orphan-school at Halle, and was entered at the university of Leipzig in 1733, where, being destined by his relations to the theological profession, he spent five years chiefly in the study of the rabbinical writings and Arabic. He was soon induced to renounce the first of these pursuits, but he became extremely devoted to the second; and his passion for Arabic books was so strong that he almost deprived himself of the common necessaries of life in order to purchase them. The learned Wolf of Hamburg having, in 1736, sent him the 'Narrationes' of Hariri, he copied it with great eagerness, and in the following year printed at Leipzig the twenty-sixth 'Consessus' with Arabic scholia and a Latin version. The success of this essay caused him to take the resolution, contrary to the advice of his friends, of going to Holland for improvement in the Arabic language. He ransacked all the Oriental treasures of the library at Leyden, whilst for his subsistence he was obliged to become a corrector of the press. He passed his time in a state of indigence and discountenance that brought upon him hypochondriac affections, the effects of which never left him. During his stay at Leyden, he made use of the advantages the place afforded for the study of medicine, and on his return to Leipzig he was presented with a gratuitous degree of doctor of physic; but his manners and habits were altogether unsuited for the obtaining of professional practice. Poverty was his perpetual companion, and his scanty resources were derived from correcting the press, translating, and performing other tasks for booksellers. His condition soured his temper, and he made many enemies by the severity of his censures. In the mean time, many valuable works in Oriental and Greek literature were occasionally proceeding from his pen, which made him well known in the learned world, and he was at length nominated rector of the college of St. Nicholas in Leipzig. Thus placed in happier circumstances as to fortune, he pursued his literary labours more according to his inclination, and fulfilled the duties of his office with exemplary diligence. At the age of forty-eight he married Ernestine Christine Müller, a young woman of twenty-nine, who was afterwards of great use to him in his editorial employments. He died on the 14th of August, 1774, at the age of 58.

The following is a list of some of the most valuable of his works, beginning with those on Oriental subjects:—1, 'Miscellanea aliquot Observationes Medicæ ex Arabum Monumentis,' 4to., Lugd. Bat., 1746, a little work of much importance to all who take an interest in the Arabic physicians, which was republished after Reiske's death by Christ. Gottl. Gruner, 8vo., Halæ, 1776; 2, 'Abulfedæ Opus Geographicum.' This translation of the Geography of Abulfeda is to be found in Büsching's 'Magazin für die neue Historie und Geographie,' vols. iv. and v., Lips. 1770, 8vo. Unfortunately Reiske did not possess sufficient mathematical knowledge to understand the systematic part of such a work. The whole of it has lately been published at Paris in Arabic, 4to., 1840, by MM. Reinaud and le Baron MacGuckin de Slane, and a French translation with notes and illustrations by M. Reinaud will shortly appear. 3, 'Proben der Arabischen Dichtkunst in verliebten und traurigen Gedichten, aus dem Motanabbi, Arabisch und Deutsch, nebst Anmerkungen,' Leipzig, 1765, 4to. This contains only a part of the poems of Motanabbi, the whole of which he had copied out during his residence at Leyden, and wished to publish. A German translation of the whole of his poems is among his unpublished manuscripts. 4, 'Abulfedæ Annales Moslemici,' Leipzig, 1754, 4to. This volume contains the translation of the Annals of Abulfeda [ABULFEDA], from the birth of Mohammed to A.H. 406 (A.D. 1015-6): it is scarcely two-fifths of that part of Abulfeda's work which treats of the history of the Mohammedans. Reiske did not translate the first part of this work, which has for its object the history of the time anterior to Mohammed. In his preface Reiske has mentioned all he has written upon Abulfeda, and the motives which induced him to publish successively and in parts his translation, notes, historical commentary, and the different indexes which were to facilitate the use of the work. He justly experienced great regret at not being able to publish the text, as he had hoped to do; and the sale of this volume was so much below what he had hoped, that he gave up all idea of printing the rest of the translation. Happily the public at the present day, through the generosity of M. de Suhm, are in possession of the Arabic text of this important work, which alone would have sufficed to assure to Reiske the gratitude of the learned world. It has been printed under the direction of M. Adler, under the title, 'Abulfedæ Annales Muslemici,' Arab. et Lat., Hafniæ (*Copenhagen*), 5 vols. 4to., 1789-1794. The translation of Reiske often degenerates into a paraphrase, which does not prevent persons who are ignorant of the language of the original from making use of it with confidence; the historical notes which are joined to it add greatly to its value, and it is only to be regretted that M. Adler has not given a table of all the proper names that these annals contain. His other works consist of editions of various classical authors, as 'Constantinus Porphyrogenitus,' Gr. et Lat., fol., Lips., 1751, 1754; 'Ciceronis Tusculanæ Quæstiones,' 12mo., Lips., 1750; 'Theocritus,' Gr. et Lat., 4to., 2 vols., Lips., 1766; 'Oratores Græci,' Gr. et Lat., 8vo., 12 vols., Lips., 1770-75; 'Plutarchi Opera Omnia,' Gr. et Lat., 8vo., Lips., 1774-82, 12 vols., of which only the first appeared during his life; 'Maximus Tyrius,' Gr. et Lat., 8vo., 2 vols., Lips., 1774; 'Dionysius Halicarnassensis,' Gr. et Lat., 8vo., Lips., 1774-77, 6 vols., of which the four last were published after his death. Some of these latter works, as well as several translations, were hastily executed in order to gain a livelihood, and most of them have been superseded by more recent and accurate editions. A complete list both of his published works and his manuscripts is given by Reiske's wife, in her continuation of his memoirs, which were published at Leipzig, 1783, 8vo., under the title, 'J. J. Reiskens von ihm selbst aufgesetzte Lebensbeschreibung,' pp. 810. His knowledge of Greek was considerable, and he is universally allowed to have been one of the best Arabic scholars that ever lived; in both these languages however he is much too bold and hasty a critic to be implicitly trusted, and his alterations and conjectures are frequently unnecessary and absurd.

REISKE, ERNESTINE CHRISTINE, whose maiden name was Müller, the wife of the preceding, and a woman of great literary accomplishments: she was born on the 2nd of April, 1735, at Kemberg, a small town near Wittemberg in Prussian Saxony. In 1755 she became acquainted with Reiske at Leipzig, where she was paying a visit. Her beauty, modesty, goodness of heart, and fondness for literature, immediately attracted his notice; and notwithstanding that he was twenty years her senior, they conceived a mutual love and esteem for each other; owing however to the war which raged all over Saxony, they were not married till 1764. This union, which contributed so much to Reiske's happiness during the rest of his life, was also of service to the cause of literature, and Christine Reiske deservedly occupies a distinguished place in the list of learned women. In order to help her husband by dividing with him his literary labours, she acquired under his instructions such a knowledge of Latin and Greek that she was soon able to understand the writers in those languages. From this time she was of the greatest assistance to him; she copied and collated manuscripts for him, arranged the various readings that he had collected, and read and corrected the proof sheets of his works. Her attachment for him and her respect for his memory are strongly shown in the supplement to his Autobiography, which she completed, from the first of January, 1770, to the time of his death in 1774. The gratitude of Reiske, and the ardour of his affection for one who lived only for him, are not less strongly expressed both in the autobiography just mentioned and in the prefaces to some of his works. On the occasion of his publishing his Demosthenes, we have the following interesting note by his wife in his Memoirs:—'When the work went to press, only twenty thalers of the subscription money had come in. The good man was quite struck down with this, and seemed to have thrown away all hope. His grief went to my soul, and I comforted him as well as I could, and persuaded him to sell my jewels, which he at length came into, after I had convinced him that a few shining stones were not necessary to my happiness.' After her husband's death she published several works that he had left unfinished; viz., the three last volumes of the 'Oratores Græci,' 8vo., Lips., 1775; 'Libanii Sophistæ Orationes et Declamationes,' Altemb., 1783-87, 8vo., 4 vols., Græce; 'Dionis Chrysostomi Orationes,' Græce, 8vo., 2 vols., Lips., 1784. She also published two works herself, one at Mitau, 2 vols. 8vo., 1778, 1779, with the title of 'Hellas;' and another entitled 'Zur Moral: aus dem Griechischen ubersetzt von E. C. Reiske,' pp. 364, 8vo., 1782, Dessau and Leipzig, containing several moral works, translated by her from the Greek into German. Concerning this last work see the 'Bibliotheca Critica,' by Wyttenbach, part viii., page 142, Amstel. 1783. She also gave to M. Boden, for his edition of the Greek romance of Achilles Tatius (Leipzig, 1776, 8vo.), the various readings of a manuscript collated by herself. After her husband's death she lived successively at Leipzig, Dresden, and Brunswick, and died at her native town, Kumberg, of apoplexy, at the age of sixty-three, on the 27th of July, 1798

REJOINDER. [PLEADING.]

RELAND, ADRIAN, an eminent Orientalist and scholar, was born at Ryp, a village in North Holland, July 17, 1676. His father was a minister of that village, but afterwards removed to Amsterdam, where Reland was educated. He made such progress in learning, that at eleven years of age he had passed through the usual classical course. The next three years he spent in making himself acquainted with the Hebrew, Syriac, Chaldee, and Arabic languages, under the tuition of Surenhusius. At fourteen he was sent to Utrecht, where he studied under Grævius and Leusden; and, three years after, was admitted to the degree of doctor in philosophy, on which occasion he sustained a thesis, 'De Libertate Philosophandi.' At seventeen he entered upon a course of divinity, under the direction of Herman Witsius and others; but he did not abandon the Oriental languages, which were always his favourite studies. After a residence of six years at Utrecht, he removed to Leyden, and soon after the earl of Portland chose him as preceptor to his son. In 1699 he was elected professor of philosophy at Harderwick, but did not continue long in that situation; for the university of Utrecht, on the recommendation of King William, offered him the professorship of Oriental languages and ecclesiastical history, which he readily accepted, and filled with high reputation during the remainder of his life. In 1713 a Society for the Advancement of Christian Knowledge being established in England, Reland became a member of it, as well as of that for the Propagation of the Gospel in Foreign Parts, instituted the year after. He died of the small-pox at Utrecht, Feb. 5, 1718, in the forty-second year of his age. He wrote and published a great number of works on sacred and Oriental learning, the chief of which are the following:—'De Religione Mohammedica Libri Duo,' Utrecht, 1705, 12mo., a second edition of which, with many additions, was published at the same place, 1717, 12mo.; 'Dissertationum Miscellanearum Partes Tres,' 1706, 1707, 1708, 12mo. These three parts, which are not always found together, comprise thirteen dissertations upon various subjects, more or less connected with Eastern history and antiquities, with the exception only of one, treating of the languages of America. 'Analecta Rabbinica,' ib. 1702, 8vo.; 'Antiquitates Sacræ Veterum Hebræorum,' 1708, 12mo.; 'Dissertationes quinque de Nummis Veterum Hebræorum,' &c.; 'De Spoliis Templi Hyerosolymitani in arcu Titiano Romæ conspicuis,' 1716, 12mo.; 'Oratio pro Lingua Persica,' ib., 1701, 4to.; and a dissertation on the Marbles of Puteoli, ib., 1709, 12mo. But his greatest work, and that in which his learning of the Eastern languages shines most conspicuous, is 'Palæstina ex Monumentis Veteribus illustrata et Chartis Geographicis accuratioribus illustrata,' which appeared first at Utrecht, 1714, 2 vols. 4to., and was reprinted at Nürnberg, 1716, 4to. Besides the above works, Reland wrote many others, as the 'Dissertatio de Philippi Imperatoris Patris et Filii credito temere Christianismo,' a funeral oration to the memory of Mary, wife of William III. of England, a dissertation on the progress of philosophy at the beginning of the eighteenth century, &c.

RELATION (Mathematics). What we here mean by this word would have been explained in the article EQUATION, if we had confined ourselves to the explanation of arithmetical algebra; but having in the articles NEGATIVE, &c. QUANTITIES, and OPERATION, endeavoured to give higher views, we are induced to insert the present article by remembering that the difficulties of such a subject are of very different kinds to different persons, insomuch that any point of view may be usefully taken with reference to some minds, and any detail upon a fundamental notion may remove misapprehension in one quarter or another. There are some who ought to find great part of the present article an unnecessary appendage to the former two, and others who may perhaps find in it nothing but necessary explanation.

All reasoning is the discovery of relations which are not evident from those which are; or rather, since the proposed result is sometimes evident in itself, reasoning is the establishment of one relation as a necessary consequence of others. The term relation would be difficult to define in a manner satisfactory to all; it is enough for our present purpose to say a relation exists between any two objects, whether of sense or intellect, whenever they have anything in common; that is to say, the common point, whatever it may be, may be made the means of referring one to the other, or bringing our thoughts from one to the other, so as to think of both at the same time, and to compare the two. All the manifold senses of the word may be derived from this one: the relationship of blood implies a common ancestry; the relationship of office, common duties. In mathematics the relation of greater, equal, or less, implies that one of the magnitudes is the same as to quantity with part or all of the other, and so on. Sameness in every respect would constitute identity; sameness in one or more respects, relation. The triangles in Euclid, i. 4, are by hypothesis related in a given manner in three particulars: a change of place shows that they can be made identical; that is, their difference before the change of place was difference of position only, not at all of form; in all that can distinguish one triangle from another, except its position in space, they are identical. We do not quarrel with the phrase that they are the same triangles differently placed, because sameness is understood with a reservation, and the preceding means that they are the same except in difference of place.

Words of identity are sometimes incautiously used to signify relations only, or words of more relation to signify kinds of relation: thus Euclid, who defines equality to consist in capability of coincidence, that is, in perfect sameness of form with difference of place, uses the word equal freely to signify nothing but equality of area, here meaning by equal equiareal. But we hold it to be exactly the same error to make a correction by introducing another general term in a limited sense; those for instance who have proposed *equivalent* instead of equiareal, have attempted to make a word which might stand for any relation of equality be confined to one of its particular meanings. In algebra there is a great want of terms, as well as of signs, significative of relation; we have in fact only one sign, =, and one phrase for it, *is equal to*. Hence proceeds either want of distinction between different relations, or the want of distinctness which arises out of such a generalization of the sign as will bring all its meanings under one.

In an algebraical expression we may have to consider its meaning, form, magnitude, source, mode of derivation, and properties. The meaning depends upon the fundamental definitions which are employed and the form; the form, upon the arrangement of the symbols; the magnitude, when magnitude is signified, upon the form and the particular values given to the symbols; so that these various sources of relation are closely connected with one another. The fundamental meaning of the sign = implies equality of quantity or magnitude, and some insist that it shall always retain that meaning. There can be no objection to any one insisting on this point for himself; but the learner, who, if he be wise, will learn all languages with the majority, even though he should afterwards teach with the minority, must make himself accustomed to various uses of this sign, as follows:—

1. The sign = means that on one side we have an operation to be performed, and on the other side the result of performing that operation by general rules, as in

$$(x+a)(x-a) = x^2 - a^2 \qquad a^7 \div a^7 = a^0.$$

Whenever the resulting form is intelligible both in form and magnitude, the resulting relation is equality of magnitude under difference of form, independently of the particular values of the symbols; but when the result is unintelligible, as is the second of the preceding results when first obtained, this relation no longer exists: the process described in INTERPRETATION makes it exist. In all such cases the relation is that of sameness of value and properties, sameness in fact of everything but form; and the relation is independent of the magnitude of the algebraical symbols.

But did no relation exist in $a^7 \div a^7 = a^0$, until we had interpreted the then unknown symbol a^0 to mean unity? We answer, that a relation did exist, namely, sameness of properties. The value of the first side is unity: the unknown symbol of the second side would be found on trial to have all the properties of the unit, when common algebraical rules are applied. If we were to refuse the interpretation, and consider a^0 as a self-contradictory symbol, we could not deprive it of the properties of a unit, or rather, we could not deprive ourselves of the knowledge that the algebraical use of it would produce the same results as the algebraical use of a unit.

To the same head may be referred the meaning of =, as connecting an infinite series with its finite source of development (or its invelopment). Arithmetical equality may not exist, for the series may be divergent; but between the development and its invelopment exists the relation of sameness of properties, and the relation of sameness of source. The infinite series $1-1+1-1+$, &c. is equated to half a unit; that is, the sign = is put between $\frac{1}{2}$ and $1-1+1-1+$, &c. *ad inf.* The relation of sameness of magnitude has no existence, for $1-1+1-$, &c., *ad infinitum*, furnishes no definite idea of magnitude; but in properties, the two are the same. This subject will be considered more in detail in SERIES.

2. The sign = means the relation of sameness of magnitude, without reference to form, and in this sense its use generally imposes conditions on one or more of the symbols employed, and always does so unless when the sign might also truly have the meaning described under the first head. Thus $2x+3 = x+4+x-1$ imposes no condition on the value of x, because the first side is only a more simple performance of the operations indicated on the second side; but $2x+3 = 21-x$ is the assertion of a relation existing which is not true of the forms, and is not generally true as to the magnitudes. The condition $x = 6$ is necessary to the truth of the relation asserted to exist. Relations of this sort, under the name of equations, are the first which meet the student at his entrance into algebra, and he frequently has a subsequent difficulty in extending the use of the symbol =. Being accustomed to see it impose conditions of magnitude, he cannot easily cease to imagine that it always does so; and he looks upon the two equations

$$\varepsilon^x = 1+x+\frac{x^2}{2}+\text{\&c.}, \qquad \text{and } x+1=2,$$

as things of the same kind, differing only in complexity. To prevent this, the distinction between *identical* equations (so called), namely, assertions of the relation described under the first head, and equations *of condition*, should be strongly marked at the outset of his course. It would even be wise to use somewhat different symbols for the two relations; thus $\equiv$ might denote the first described relation, and = the second. The learner might drop the slight distinction which exists between the two symbols when he finds himself able to do without it; but we are satisfied that those who had once learned to use it would never think the time was come when they might safely drop it.

3. The sign = means the relation of algebraical identity between the results of different operations, when the symbols are not symbols of magnitude, but of OPERATION: that is, it asserts the relation of sameness of effect between the two operations which are written on one side and the other of it. And here it is in truth used in the first sense described, the difference being in the meaning of the symbols, not in that of the relation. And here again there is the distinction between the case in which the relation is explicable from definitions, and that in which it requires interpretation. Thus in the relation $(1+\Delta)^2 = 1+2\Delta+\Delta^2$, we can prove and verify that the operation $1+\Delta$ is of that sort which if performed twice following, will yield the same result as the sum of the results of the operations 1, 2Δ, and Δ^2. But when, having established, as in the article cited, a right to the use of all the ordinary transformations of algebra, we come to $1+\Delta = E^D$ and $D = \log(1+\Delta)$, we have results of which the first side only is explicable, and the second requires interpretation. It might be satisfactory to consider such symbols as $\log(1+\Delta)$, &c. in no other light than as abbreviations of the series into which they might be developed in common algebra; but as such a use of interpretation seems to a beginner to be more arbitrary than it really is, we may point out how to make the passage in a somewhat more guarded manner, presuming the reader to be perfectly well acquainted with the results of the article OPERATION.

If A, B, &c. stand for symbols of operation, then $A \pm B$, AB, $A \div B$, are compound results of operation, which are capable of and actually receive a distinct definition. Similarly A^n is also deducible in meaning from the definition when n is any number, whole or fractional, positive or negative; but A^B, where B is also a symbol of operation, cannot be immediately explained from definition. But it is to be remembered that an algebraic quantity may be susceptible of different definitions, though really amounting to the same definition. Sometimes nothing more than a mere change of the form of words will render a notion capable of being rationally extended further than it could have been before the change was made. For instance, in FRACTIONS, we understand the division of 7 into 3 equal parts, and into 4 equal parts; but a division into $3\frac{1}{2}$ equal parts is a set of words without meaning. But if we only speak of taking parts of which three make 7, and other parts of which four make 7, it is perfectly easy to imagine parts such that three parts and half a part make 7. Can we not then take such a method of defining A^B as, without in any way altering its common meaning, shall present that common meaning in a form which will be intelligible when A and B are symbols of operation.

In BINOMIAL THEOREM it is proved that the equation $\phi x \times \phi z = \phi(x+z)$ can only be satisfied for all values of x and z, by $\phi x = C^x$ where C is independent of x.

If then we propose the equation—

$$\phi x \times \phi z = \phi(x+z) \quad , \quad \ldots\ldots (1)$$

the only solution of both must be C^x. It is easy enough to show that—

$$C^x . C^z = C^{x+z},$$

the proof referred to shows that C^x is the *only* solution of this equation. If z and x be symbols of operation, and if by ϕx we mean a combination of operations performed with x, and by $\phi x . \phi z$ the result of successively performing the operations ϕz and ϕx, we may denote by y^x an operation which is such, that calling it ϕx, the successive performance of ϕx and ϕz is equivalent to that of $\phi(x+z)$; and that, calling it ψy, the successive performance of ψy and ψz is equivalent to that of $\psi(yz)$. If we want to define the particular operation A^x, we must add to the equation (1) the following—

$$\phi(1) = A.$$

Thus, let it be the definition of ε^D, D being a symbol of operation, that we have here an operation such that if it and $\varepsilon^{D_\prime}$ were successively performed, the result would be the same as if $\varepsilon^{D+D_\prime}$ were performed at once; this last symbol implying that the operation $D+D_\prime$ is used in the same way as D in the first. Moreover, let it be understood that if D were 1, that is, if the operation D produced no alteration in the function operated on, the result of ε^D would be simple multiplication by ε. There is nothing in this definition which is unintelligible, though there is something unknown. An operation is defined by means of itself; the definition must then be developed before its object can be understood, but it is not the less a definition, that is, a description of some one operation, and a distinction between it and every other. Thus, in common algebra, the magnitude of x may be defined by an equation, say $x = 12-x$. Here x is only given in terms of its unknown self, but it is not the less defined to be 6, and nothing but 6. When the step above described has been made, it is (owing to the demonstrated connection of the rules of common algebra with those of the calculus of operations), the same process to prove that

$$\varepsilon^D = 1+D+\frac{D^2}{1.2}+\ldots.$$

when D signifies an operation, as when it signifies a quantity.

The definition of log D is that this operation is the inverse of ε^D with respect to D; so that $\log \varepsilon^D$ means D. Those functions which in common algebra are trigonometrical [SINE] cannot be defined in the subject of which we are speaking, otherwise than by reference to the well-known exponential forms. Thus, D denoting an operation—

$$\text{Cos D means } \frac{1}{2}\left\{\varepsilon^{D\sqrt{(-1)}} + \varepsilon^{-D\sqrt{(-1)}}\right\}$$

$$\text{Sin D means } \frac{1}{2\sqrt{(-1)}}\left\{\varepsilon^{D\sqrt{(-1)}} - \varepsilon^{-D\sqrt{(-1)}}\right\}$$

It might perhaps be said that though we have constantly used the word relation, yet we have considered nothing but identity, that is, either identity of magnitude, form, process, or properties; but that the term in common life refers to something short of complete identity, frequently meaning mere connection, and sometimes only analogy, or even nothing more than resemblance. We answer, that relation always refers to identity of some sort. For example, there is a relation between the position of the sun and moon and the state of the ocean. Here the word means merely a connection; but this connection involves an absolute identity: having given the position of those heavenly bodies with respect to any place, together with the direction and quantity of their motions, the height of the water at that place is connected with the quantities which express those positions and motions by an equation or a mathematical identity. Resemblance again means identity in some respect, or near approach to identity: analogy, a term generally applied to relations of similarity, will be found to admit of the word sameness being used instead of similarity. Thus, when we say that substance is formed from *substare* in a manner similar to that in which distance is formed from *distare*, the analogy asserted is one of absolute identity (of mode of derivation).

Reasoning by analogy is either the same thing as common reasoning; or else analogy is but another word for induction. If A give B, and C have something in common with A, it may be a necessary consequence that C gives D; D being connected with C in the same manner as B with A. But this happens only when the following of B from A is a necessary consequence of that which A and C have in common, and of that only: in which case the deduction of D from C by analogy with the deduction of B from A, is only an assertion of the possibility of applying the same mode of proof to that part or property of C which was previously applied to the same part or property of A. But when we conclude by analogy of a horned animal that it is not carnivorous, as it is said; that is, when we conclude that the horned animal of which we speak will resemble all other horned animals which we know, in every point in which they resemble each other, we apply no other process than the establishment of a highly probable result by induction.

Reasoning by pure analogy is then not absolutely demonstrative reasoning, except in the case above described, in which we want no new name for the process. But attention to analogy in the structure of definitions, and in the route of investigation, is necessary to the success of many inquiries, and gives clearness and saves time in all. Indeed it may be taken as a maxim that whenever there is any species of resemblance pervading the results of two branches of inquiry, there ought to be a reason for that resemblance in the nature of the two subjects, expressed by a resemblance of the notations used; and this reason ought to be made prominent and insisted on.

For instance, we have two distinct *algebras* [NEGATIVE, &c. QUANTITIES], which, for temporary distinction, we may call arithmetical and geometrical, using the same symbols in the same manner, but proceeding upon meanings given to those symbols which appear altogether different. The only reason given to the student in the article cited, to justify the definitions of the latter, or geometrical algebra, was that they would be found to answer a certain purpose, namely, to make all theorems in the earlier algebra true, when no other alteration was made than that of the meanings of the symbols. It is now to be asked, why have the new definitions that property? what relation have they to the old ones which gives the results of the two a perfect community of form? The answer to this question is not very difficult; but it will require us first to consider what are the operations of common arithmetic, and how they are to be described in terms of the simplest notions of the science.

The fundamental operations of arithmetic are addition, subtraction, multiplication, and division. Of these we may make the definitions of subtraction and division follow from those of addition and multiplication: thus subtraction is the process which destroys the effect of addition, and division that which destroys the effect of multiplication. It may be said however that we can resolve all operations into one only, and its inverse: the direct operation being the simple repetition of a unit; and its inverse, the ascertainment of the quantity which will by simple repetitions make a unit. Since however the analogies with which we have here to do are not in any way connected with the distinction of whole numbers and fractions, we will confine ourselves to whole numbers, and, choosing a unit, make repetitions of that unit the sole objects of consideration.

The fundamental ideas of arithmetic are, first, that absence of all magnitude which must precede the consideration of any particular number; secondly, the particular magnitude which we choose for repetition, and to which we refer other magnitudes. Nothing and unity are the names of these ideas; and 0 and 1 are their well known symbols. The first, 0, reminds him who uses it, of the state in which he is antecedently to thinking of any number; the second, 1, of the successive accessions by which he passes from one object of consideration to another. If 0 do not present itself before we can think of any number, it is that we avoid it by an act of memory; but if, for instance, a person had forgotten what seven was, as a young child might do in learning arithmetic, he would be obliged, beginning from 0, to construct 7 by repeated accessions of a unit each time.

Now addition of one number to another is a process which merely puts a number in the place of *nothing*, and proceeds to count from that number in the same manner as when we form the number to be added from 0. Thus, to add b to a we do with a what we should have done with 0 to form b: to add 4 to 3, we do with 3 what we should have done with 0 to form 4. If this last operation were performed on the fingers, we should first complete three, and then count the fingers which make four from and after the completion of the three; thus—

$$4=0+1+1+1+1$$
$$3+4=3+1+1+1+1$$

This definition of addition, namely, that '$a+b$ is a direction to do that with a, which would give b if a were nothing,' will now be put by for a moment, until we are ready to apply it in the construction of the new algebra.

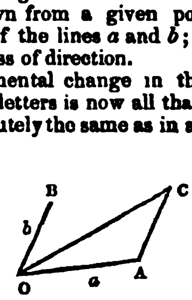
Multiplication of one number by another is a process which puts a number in the place of *unity*, and proceeds to use that number in the same manner as we use unity when we make another number. Thus, to multiply a by b, we do with a what we should have done with unity to make b: to multiply 3 by 4, we do with 3 what we should have done with unity to make 4. Thus,

$$4=1+1+1+1,$$
$$3\times 4=3+3+3+3.$$

The definitions of subtraction and division are then obtained, as before described, by the supposition of inverse operations, or operations destructive of the effects of addition and multiplication.

In consequence of the preceding considerations, we shall pass from the limited to the more extended algebra without anything of any arbitrary character, except only the choice of a meaning for the fundamental symbols. In arithmetic, the symbols a, b, c, &c. mean simply numbers; let their meaning in the geometrical algebra be not numbers but lengths, or if numbers, let them be numbers of lengths, a given length being taken as the unit. And let each symbol be expressive not only of a length, but of a length in some particular direction; by which we mean, that two lines are not to be denoted by the same symbol, unless they have not only the same lengths but the same directions. Imagine all lines to be drawn from a given point; then $a=b$ denotes coincidence of the lines a and b; that is, sameness of length and sameness of direction.

This one fundamental change in the meaning of the things signified by letters is now all that need be made; for all the rest is absolutely the same as in arithmetic. For example, what is $a+b$? Let OA and OB be the lines represented in length and direction by a and b; having completed



OA, that is, having passed from O to A through the proper length and in the proper direction, do that which would have given OB if OA had been nothing, as if A had been at O; that is, draw AC equal and parallel to OB, and in the same direction. The point C thus obtained terminates a line OC, the length and direction of which is therefore to be denoted by $a+b$, since every process is to resemble that of arithmetic in everything but the meaning of the objects of operation.

Again, required the meaning of ba? We must now choose a length and direction which is to be represented by 1; let this be OU. We are now to do with OA as a what we should have done with OU to make OB. Suppose for simplicity that OB is double of OU. To turn OU into OB, we must double its length, and let it revolve through a certain angle UOB. Do this with OA; that is, double its length and make it, thus doubled, revolve to the position OC, so that the angles UOB and AOC are equal. Then OC must be that which is represented by ba; and the angle UOC is the sum of the angles UOB and UOA.

If we examine the fundamental definitions of the geometrically defined system of algebra [NEGATIVE, &c. QUANTITIES, p. 133], we shall find that we have here deviated enough to deduce them all, and that we have done it by pure analogy. But also remark that analogy here means nothing but an identity of process; we have described the processes of addition and multiplication in terms which connect them so closely with the objects to which they are applied, and at the same time make the process so distinct from the subject-matters of the process, that when we change the subject-matter, we can still preserve the process. If then any other subject-matter could be found, such that, with reference to meanings of a and b derived from it, $a+b$ and ab could be consistently defined, or rather deduced, from 0 and 1, a new application of the rules of algebra would follow.

In the calculus of operations, the same steps might be made; and when this branch of algebra consisted of nothing but the separation of the symbols of operation and quantity in an arbitrary manner [OPERATION, pp. 442, 443], analogy was the species of relation by which the deduction of results from this separation was connected with the results of common algebra. But this analogy was only the guide to the results, and not the proof of them: it became a proof when it was shown that the validity of the common algebra itself depended, not upon the whole meaning of the symbols, but upon that part of it which was preserved in the meanings of the symbols of operation.

RELATION, RELATIONAL. [NOTION, NOTIONAL.]

RELATIVE MAGNITUDE. [RATIO.]

RELATIVE MOTION. [MOTION.]

RELATIVE PRONOUN. The relative pronoun is so called because it relates to some object mentioned just before, which object is usually termed the antecedent. The English language possesses two words for the relative pronoun, *who* or *which*, and *that*. The word *what* must also be regarded as a relative, for it evidently contains the same root as *who* and *which*; it is generally used in the sense of *that which*, as 'Let them say *what* they will.' The terms *who*, *which*, and *what* are also used as interrogatives, and contain the same root as the Sanskrit *ka-s*, the Greek *ὅς*, the Latin *qui*, the Gothic *hver*, &c. The term *that* is evidently the same word as the demonstrative pronoun. In the same way we find that the Greek article, which was originally a demonstrative pronoun, is also used as a relative; and the German language likewise possesses two forms for the relative, *welcher* and *der*, the latter of which is also a demonstrative, and is the same word as the English *that*. According to Bopp (*Vergleichende Grammatik*, p. 163), the relative in Zend is also used as a demonstrative.

In English the relative is not unfrequently omitted. Thus most persons would say, 'The first school I was at,' and not 'The first school which I was at.' This omission is condemned by some grammarians, but is authorised by the usage of our best writers. The omission however seems only admissible in familiar speaking and writing, and is a great defect in any composition of a serious or elevated character.

RELATOR. [INFORMATION.]

RELEASE. 'Releases are in divers manners, viz. releases of all the right which a man hath in lands or tenements, and releases of actions personals and reals, and other things.' (Litt. § 444.)

The former kind of release may be considered as a species of conveyance, and the instrument of release must be a deed. The operative words of release are *remise*, *release*, *renounce*, and *for ever quit claim* (an abbreviation or corruption of *quietum clamasse*). According to Littleton (§ 508) a release to a man of all demands is the best release that can be made, 'and shall enure most to his advantage;' but Coke remarks that 'claims' is a word of still more extensive import. The parties to a release are the releasor and releasee; the releasor is he who quits or renounces that which he has; the releasee is he who acquires what the other gives up, but he cannot acquire anything by the release, unless he has some estate in or right to the thing which is the object of the release.

Releases are either of an estate in land or of a right to land; or they are releases of things personal. Releases of estates in or rights in land require to be considered separately.

In order that a Release of an estate in land may have its intended effect, there must be privity of estate between the releasor and releasee; that is, the estates of the releasor and releasee must have been acquired by the same conveyance or title, or the one estate must have been derived immediately out of the other. There must be this privity whenever the Release of an estate operates either by way of enlarging the estate of the releasee, or by way of passing to him the estate of the releasor.

It is not in all cases necessary that the person to whom the release is made should be in the actual possession of the land or that he should have the estate immediately preceding that of the releasor. If land be given by C, who is tenant in fee-simple, to A for years, remainder to B for life, C may release his reversion either to A or to B; in the former case A will acquire the reversion expectant on B's life estate; and in the latter case B's remainder will merge in the reversion, which will become an estate in possession on the determination of A's estate. This is commonly called a release which enlarges an estate; but in the case supposed, if the release is made to A, his estate is not thereby enlarged, and the effect is just the same as if C made him a grant of the reversion. The rule of law is undoubtedly true that 'whenever a release doth enure by way of enlarging an estate, there must be privitie of estate, as between lessor and lessee, donor and donee' (Co. Litt., 273, a); but there must also be privity, as in the case supposed, when no enlargement of the estate is made by the release. If C, tenant in fee simple, had originally granted the estate to B for life, and B had made a lease for years to A, a release of the reversion in fee from C to A would have no effect as a release, because there is no privity of estate, as above defined, between A and C. Such a release may however operate as a grant of the reversion, if there are sufficient words for that purpose. When lands are in possession of a lessee at will, for years, or for life, or of an assignee of such lessee, the lessor may release either to the lessee himself, or to his assignee. But a release by the original lessor to an under-lessee, as above stated, will not operate as a release. A copyhold tenant is, strictly, tenant at will to the lord who is the owner of the freehold, and therefore the lord may enfranchise the copyhold by release; but it is more usual to do it by lease and release, by way of greater caution.

In order that the release may operate to the enlargement of the estate of the releasee, it must contain proper words. Therefore if he who has the fee in reversion or remainder intends to release his estate to a tenant for years or for life, he must release to such tenant and his heirs. If he simply release to the tenant for life, the releasee will have no greater estate than he had before; and if he simply release to the tenant for years, the tenant acquires the estate only for life. (Litt., 465.)

If a lease is made, at common law, of lands in possession, the lessee has no estate till he enters, and therefore can accept no release from the lessor; but a release from the lessor to the lessee before entry of all his right in the land, extinguishes the rent. In the common conveyance by lease and release, it is usual to give the intended releasee an estate in the land for a year by bargain and sale, which by the statute of uses becomes a vested estate, and the bargainee is therefore qualified to take a release without actual entry, which would be necessary in the case of lands in possession, if the lease were made at common law, though not requisite in the case of a lease of lands in reversion.

A release may operate by passing the releasor's estate to the releasee, without enlarging the estate which the releasee already has; and this takes place in the case of joint tenants and coparceners. Joint tenants of an estate have one undivided title, and they can only convey their estates to one another by release. Coparceners have only one title, for they all make one heir, but they also transmit to their heirs separate estates. Accordingly coparceners can either release to each other or convey their estates by feoffment. In these cases it is not necessary to use any words of limitation in the release, for as the joint tenants and coparceners have all one title to their estate, whatever it may be, a release from one to another passes all the estate of the former to the latter, without any words of inheritance.

If there are three joint-tenants, and one of them releases his estate to another of them, such other becomes joint-tenant of two-thirds of the land with the remaining tenant, and he holds the released one-third as tenant in common with his remaining companion. If a lease be made to two persons, one may release to the other before entry; for there is privity of estate between them, and the release does not operate by enlargement, but by extinguishment of a right.

A man may release all his right in or to lands, and such release will comprehend all his rights at the time, but not future rights. An expectant heir cannot release the right which he may have to his ancestor's estate. A right, in order to be capable of being released, must therefore be an existing right and not a possibility. Sometimes however a release, though it cannot operate as such, may operate as an estoppel. In a particular case (Bensley *v.* Burdon, 2 S. and S., 519) a son was estopped under a release made by him in his father's lifetime, by the allegation of a particular fact, which was held to conclude the son who made it.

A right may be released to any person who has an estate in the land, either in possession, reversion, or remainder; but if the right be to an estate of freehold, it can only be released to a person who has an estate of freehold. Such a release will be for the benefit of all persons who are entitled to the land by the same means as the releasee.

There is also Release by act or operation of law, as it is termed; that is, from certain acts or events, which are not a direct release, the legal conclusion of a release follows. Instances of this kind of release often occurred in former times when disseisins were common, and the following is given as an example: if a disseisee disseise the heir of the disseisor, and make a feoffment, this amounts to a release of the right. (Co. Litt., 264, b.)

A Release, not considered as an instrument of conveyance, is the giving up or discharging of a right of action or suit which one man has against another. This release may be either by act of law or by deed.

If a creditor makes his debtor his executor or one of his executors, the debt is legally extinguished as soon as the creditor dies, though there can be no legal evidence of this extinguishment until the executor has obtained probate of the will. The ground of this legal conclusion is, the union of creditor and debtor in the person of the executor, who would be a necessary party to an action at law against himself. But in equity so far is the debtor from being released, that the debtor executor is considered to have received the debt, and to have it as assets in his hands. Accordingly in a suit in equity against him, he may be ordered to pay the amount of the debt into court, upon admitting it in his answer. If a debtor appoint his creditor his executor, the creditor executor, both at law and in equity, may retain his debt out of the assets which come to his hands, provided he does not thereby prejudice creditors of a superior degree. If a woman marries her debtor or creditor, the extinguishment of the debt is a necessary consequence.

In a Release of this kind also the proper words are *remise*, *release*, and *quit-claim*, but any words are sufficient for the purpose which clearly express the intention of the parties to the deed. If a man covenants with another that he will never sue him, this is legally construed to be equivalent to a release, because the same end would be ultimately effected by virtue of this covenant, as if there were an absolute release. But there are cases in which a perpetual covenant not to sue one debtor will not discharge a co-debtor. (Hutton *v.* Eyre, 6 Taunt., 289.) A covenant not to sue for a limited time cannot of course have the effect of a release.

All persons may release, who are not under some legal disability, such as infancy. A husband may release a debt due to his wife, because he is the person entitled to receive it; but his release of a debt due to the wife extends only to such debts as are demands at the time of the release. A partner, or other co-dettee, may also release a debt due to him and his co-partners. An executor may, at law, release a debt due to him and his co-executors as such; and one of several administrators has the same power: but such releases are ineffectual in equity, unless they are made in the due discharge of the executor's duty. Though one of several co-plaintiffs may release a cause of action, a court of law will set aside the release, if it is a fraudulent transaction.

A release may be set aside in equity on the ground of fraud, a term which will include every act of commission or omission that renders the transaction unfair, such as misrepresentation or suppression of facts important to be known to the releasor. A plea of a release is no answer to a bill in equity which seeks to set aside the release on the ground of fraud, or which, anticipating a plea of the release, charges that it was fraudulently obtained, unless the fraud which is charged is put in issue in the plea, and sufficiently denied by answer. The principle of this is fully and clearly stated by Lord Redesdale. (Roche *v.* Morgell, 2 Scho. and Lef., 730.)

It is a general rule that a stranger to a deed cannot maintain an action upon it; for covenants in a deed expressed to be made between parties do not give a right of action to a person not a party to the deed, though he is mentioned in it. This principle is applicable to the case of a release; for a release expressed to be made between certain parties cannot be pleaded as an answer to the claims of the releasor against a third party, even if such release should profess to discharge such third party from all such claims. A release made to one of several joint debtors who are also severally bound, discharges them all, and the reason given is, that 'in such a case the joint-remedy being gone, the several is so likewise;' the rule applies to releases by operation of law, and is true in equity also.

The releasor may have demands against another, both in his own right and in another right, such as that of executor for instance; and accordingly a question sometimes arises whether the release extends to demands in both rights, when the release contains no clear declaration of the demands to which it extends. If this ambiguity exists, it seems to be settled that the release will only extend to such claims as the releasor has in his own right, if he has any demands in both rights; but if he has only demands in right of another, the release will operate upon them. If a man who has a rent-charge issuing out of a certain number of acres of land, releases his right in any part of the land, he releases all the rent, for it is charged on all the land, and not on any part. A release of all demands means all demands which exist at the time of the release, and it does not extend to anything which, at the time of the release, is not a demand, but afterwards becomes a demand. It is generally considered that a release of all demands would extend to a rent-charge, or a rent-service, parcel of a seignory in gross (but not to a rent-service incident to a reversion), but a release of all actions could not extend further than to a release of arrears of rent then due. Though a release of all actions is not a release of a sum of money not then due, it is said that such a release made before the day of payment appointed by the condition of a bond would be effectual; a bond being an acknowledgment of a present debt, defeasible by a condition subsequent, which does not prevent the right of action from vesting in the mean time.

A release is generally so expressed as to include all demands up to the day of the date of it; but in this case the day of the date is excluded from the computation. If the release extends to all demands up to the making of the release, this will comprehend all demands up to the delivery of it.

It is usual for releases to contain very general words which, in their literal signification, may comprehend things that the releasor does not intend to release. But whenever it can be clearly shown, as for instance by a particular recital in a deed, that the general words of release were intended to be limited, such construction must be put on them. Parol evidence is not admissible for the purpose of limiting or e…

larging the words of a release; but, as in the case of wills, it may be admitted where a difficulty arises in applying the words of the instrument to the facts of the case, for which purpose the state of the facts at the time of the release must be ascertained by extrinsic evidence.

RELICS (in Latin, 'reliquiae') is a term used to signify the remains, bones, or garments of departed holy men, which are honoured by the followers of the Church of Rome. During the first ages of the Christian Church, martyrs were held in veneration; and their relics were treasured up as something sacred. The anniversary of their martyrdom was celebrated by assemblies of the faithful, held round their tomb or on the places where they had perished, and chapels and sanctuaries were raised on the spot. The blood of the martyrs was eagerly collected with sponges, and other demonstrations of religious enthusiasm were exhibited; but the church had not sanctioned any worship of those mortal remains. In the fourth and fifth centuries the previous veneration for the saints became a kind of worship with many people; astonishing miracles were said to be performed by fragments of their bones or garments, and pilgrimages were undertaken to obtain those relics. Helena, the mother of Constantine, went to Palestine, and is said to have found the identical cross on which Christ suffered. [PILGRIM.] The use of images and that of relics as accessories to church worship seem to have grown up together during that period. Towards the end of the sixth century, Pope Gregory I. displayed a great veneration for relics. There is a letter of his to the empress Constantina, who had asked him for a part of the body of St. Paul, in which he excuses himself by saying that it was not the custom of the Romans, and, in general, of the Christians of the West, to touch, much less to remove the bodies of saints; but that they put a piece of linen called 'brandeum' near the holy bodies, which is afterwards withdrawn, and treasured up with due veneration in some new church, and as many miracles are wrought by it as if the bodies themselves were there: he adds that they were much surprised at the Greeks removing the bones of saints from place to place; but that in order not to disappoint the piety of the empress, he would send her some filings of the chains which St. Paul wore on his neck and hands. This letter is quoted by Baronius, Fleury, and other church historians. From that time the veneration for relics increased, till it became, during the middle ages, a vulgar superstition and disgraceful traffic; and the abuse has been censured by many sincere Roman Catholics. It was ordered by several synods that no relics should be exposed to view without the sanction of the local bishop. Pope Innocent III. forbade the sale of relics. The Roman Catholic Church however admits that the relics of saints have performed and may still perform miracles; and that they are a proper object of veneration.

(*Bibliothèque Sacrée, par les Pères Richard et Giraud*, articles 'Reliques' and 'Saints,' 3rd section, 'Reliques des Saints;' and also Father Honoré de Sainte Marie, *Dissertation sur les Reliques;* and the Abbé de Cordemoi, *Traité des Saintes Reliques*.)

RELIEF, RELEVIUM, a burthen incident to feudal tenures, being a sum of money paid to the lord on the admittance of a fresh tenant. It is a relic of that state of things in which the succession was not strictly speaking of right, but at the will of the lord, who required the payment of such an acknowledgement for the concession. It became however so much the custom for the lords to admit the sons or near kindred (heirs, as we now say) to the inheritance of the ancestor, that a custom became established of doing so, and out of the custom grew the right of inheritance. The money however which had been paid for admission in the former state of things, continued to be paid when the succession of the next heir had become what is called matter of *right*.

Bracton gives what is probably the true etymology of the word. 'Relevia,' says he, are so called, 'quia hereditas quae jacens fuit per antecessoris decessum, *relevatur* in manus heredum, et propter factam relevationem.'

RELIEF. [BASSO RILIEVO.]

RELIGION is a Latin word which, according to the common derivation of it (from *religare*), means a principle which acts as a *restraint* on the conduct of man. In its more general sense it is used as an abstract term to denote our *ideas* of the existence and character of a Divine Being, to whose power man are more or less subject. Thus we speak of *a sense of religion* and *the duties of religion*, and we call a man who regards such subjects as matters of great importance a *religious person*. But as different views have prevailed of the nature of the deity and the relation in which man stands to him, various systems of religious belief have sprung up, and each of those systems is called a *religion*. Thus we speak of the Greek, Hindu, Jewish, Christian, and Mohammedan religions. The word is also popularly used to express the attention of individuals to the doctrines and duties of the particular religion which they may have embraced. In this sense it is synonymous with *piety*.

The subjects with which religion has to do are God and man considered in the relation in which they stand to each other. It consequently includes all the philosophical questions which can throw light upon that relation; for example, those which respect the nature of the deity, the notions of infinite space and infinite duration, the existence and offices of spiritual beings, the origin and destiny of the human race and of the world they inhabit, the immateriality and immortality of the human soul; and also all the practical questions which arise out of that relation, such as the duties which men owe to God and to each other, and the consequences which God may have appointed to follow different courses of action. All impressions, notions, and belief upon these subjects, whether formed into a system or not, constitute what we call *religion*, as distinguished from *theology*, which is the science by which these ideas are reduced to a systematic form, their laws investigated, and their origin and results traced out. [THEOLOGY.]

The sources from which our notions of religion are derived are either the so-called laws of nature and the constitution of the human mind, or direct information given to us upon the subject by the deity himself, whether such information be embodied in any lasting form, or handed down from one generation to another by oral tradition. Religion derived from the two former sources is called *natural religion*; from the last, *revealed religion*. [REVELATION.]

The fundamental principle upon which all religion rests is the notion of the existence of a Being whose power over us is absolute, whose nature is either perfect in excellence, or at least far superior to ours, to whom we owe certain duties, and from whom we have much to hope and fear. The existence of such a Being is proved by the evidences which the objects of nature present of perfect design, of fixed order, of power sufficient to accomplish everything which we can conceive that does not involve a contradiction, and which we therefore conclude to be infinite, and of benevolent provision for the wants of living creatures. Apart from all such evidence, the belief in the divine existence seems to be strongly impressed on the human mind, so strongly indeed, that it is a matter of great doubt whether even professed atheists have been really such. Lastly, this truth may be the subject of revelation; for revelation does not, as may at first sight seem, imply as a fact *previously* known the existence of the Being from whom it comes. To the first recipients of the revelation the very fact of their finding themselves possessed of the knowledge of truths beyond the range of human experience would be a sufficient proof of the existence of a superior Being, from whom they had, in whatever way, obtained such knowledge; and if, in making known the revelation to the world, these persons should display a command over the laws of nature beyond the compass of human power, or an acquaintance with future events beyond the reach of human knowledge, these miracles and prophecies would prove the existence of a superior Being, from whom they had received the power to perform the one and the foreknowledge implied in the other. Thus the revelation itself furnishes a proof of the existence of the before unknown revealer. We do not inquire whether the divine existence is really proved in either or all of these different ways, because the object of this article is to explain the nature of religion, not to establish its truths.

The belief in a God leads at once to the practice of worshipping him, on the very same principle on which all dependents honour and look up to those in whose power they are placed.

The existence of a God once proved, the next question is, In what relation do we stand to him? Are any laws laid down for our conduct? Are we responsible to him for keeping or breaking those laws? Are any rewards and punishments appointed for obedience and disobedience?

To these questions it does not appear that natural religion can give a perfectly satisfactory answer, though no one can read Bishop Butler's admirable work, 'The Analogy of Religion, Natural and Revealed, to the Constitution and Course of Nature,' without being astonished at the amount of information on these subjects which it is there shown that the contemplation of natural phenomena reveals. It seems also that a general undefined notion of responsibility is associated in nearly all human minds with the idea of divine existence, at least a sense of responsibility sufficient to excite pleasure when we do what we believe to be good, and remorse when we do what we believe to be evil. Again, the connection which we find generally existing between vice and misery on the one hand, and virtue and happiness on the other, impresses upon us the idea that there does exist such a thing as retributive justice. But at this point we encounter the great difficulty of natural religion. Though the general law according to which the affairs of the world appear to be governed is, that virtue is followed by happiness, and vice by misery; and though a full knowledge of the circumstances of every case which appears an exception to that law might show us that more real happiness is enjoyed by a virtuous sufferer than by a prosperous sinner, yet it cannot be denied that daily experience furnishes us with exceptions to this law, numerous enough to throw great doubt upon its reality, if the period of human existence ends with the present life. Accordingly we find the doctrine of a future state forming a part of all religious systems, and generally connected with some notion of rewards and punishments. And this again is a branch of religion which, though it may be made to appear probable by arguments drawn from nature (we must again refer the reader to Bishop Butler's work), does not appear to be susceptible of satisfactory proof without a divine revelation. In the opening of the Epistle to the Romans there is an admirable though concise argument on the force and extent of natural religion (*Rom.*, i. 19): 'Because that which may be known of God is manifest in them; for God hath showed it unto them. For the invisible things of him from the creation of the world are clearly seen, being understood by the things that are made, even his eternal power and Godhead; so that they are without excuse: Because that, when they knew God, they glorified him not as God, neither were thankful; but became vain in their imaginations, and their foolish heart was darkened.' And again (*Rom.*, ii. 14): 'For when the Gentiles, which have not the law, do by nature the things contained in the law, these, having not the law, are a law unto themselves: Which show the work of the law written in their hearts, their conscience also bearing witness, and their thoughts the meanwhile accusing or else excusing one another.'

Now if there be a supreme moral governor who rules the world by fixed laws, who has appointed rewards and punishments as the recompense for obedience and disobedience, and who has constituted man so that he shall exist in a future state to receive that recompense, the question is naturally suggested whether there be any means by which the consequences of disobedience may be averted. The experience of human governments proves that it would be unsafe to pardon a criminal merely upon his repentance; and analogy would therefore lead us to conclude that so loose a principle of forgiveness cannot be admitted into the divine government. Or even if this principle might be safely acted upon in some few cases, we should gain nothing more than a vague hope of mercy, being still left without any reasonable ground for expecting it. Justice must be an attribute of the ruler of the universe, and natural religion affords us sufficient proofs of his goodness to justify us in believing that he is also willing to show mercy. The question that remains to be answered is, how his mercy can be shown without injury to his justice; and the importance of this question is enhanced by the consideration that the great majority of mankind (experience would justify us, apart from the Christian doctrine of universal depravity, in saying all mankind) need the divine forgiveness for at least some actions of their lives. It is the highest province of religion to furnish an answer to this question; and here natural religion entirely fails us, for if left to it, the utmost we could do would be to rest in the exercise of an humble faith that some provision has been made by God for the just forgiveness of our sins, though the nature of that provision be unknown to us. The matter belongs to revealed religion, and accordingly we find in nearly every religion professing to have a divine origin, and in many others, the doctrine of atonement; that is, of a satisfaction for sin, in virtue of which the actual transgressor may be released from the consequences of his guilt.

On whatever grounds systems of morality may be based by ethical writers, it is beyond a doubt that in the minds of men in general there is an inseparable connection between religion and morality, the former furnishing alike the rule and sanction of the latter. The positive morality of any people will always depend on the nature of their religion. The attributes which they attach to the divine character will be a standard for their own conduct, and their opinions respecting the recompense appointed for virtue and vice will determine the strength of the motives on which they act; while their moral system will be greatly affected by their views upon the subject of satisfaction for guilt. When, as is generally the case, the same religious principles are found to pervade a whole community, the positive morality which is formed upon those principles has a direct influence on legislation, and the sanctions and rites of religion are brought by the legislator to aid in working out his institutions, and thus religion becomes interwoven with the social and political system.

These then are the elements which seem to be contained in any religion suited to the wants of man; that there exists a supreme Being who possesses absolute power over man and the material universe, and all creatures therein, and who is to be worshipped by all his rational creatures: that he has laid down laws for our conduct, by our obedience or disobedience to which we subject ourselves to a recompense of reward or punishment, which recompense is awarded partially in the present life, but more completely in a future state, in which we are so constituted as to exist after death: that a provision has been made on behalf of those who feel that their conduct has subjected them to the divine displeasure, by availing themselves of which they may escape the consequences of their guilt without detriment to the equity of the divine government; and lastly, that there are certain practical rules of conduct by which the intercourse of men with each other ought to be governed, and by an attention to which the stability of the social system may to a great extent be ensured. And all these elements of religion are susceptible of proof, either from nature, or from human experience, or from revelation.

When we look at the different religious systems which have prevailed among the various divisions of the human family, we find the fundamental idea of the divine existence contained in them all; for the testimonies of modern travellers and of antient history concur to show that, as far as our knowledge extends, there is not nor ever has been a people utterly ignorant of the divine existence, however debased in other respects. Even where polytheism and idolatry have existed in their grossest forms, we can generally trace some notion of a supreme divinity, who is regarded as the origin of all other existences. The character of the worship which is paid to the divine Being is always found to be materially affected by the difficulty of conceiving spiritual objects. Hence the almost universal prevalence of idolatry; of which the earliest form appears to have been the worship of the heavenly bodies, which, as being the sources of light and heat and all vivifying power, were regarded as the fittest representatives of the deity. Then came the worship of the powers and objects of nature in general. The heaven, earth, and seas, the mountains, woods, and rivers, were peopled with divinities, and these were multiplied by assigning to many of them fixed abodes in particular places. Virtues and vices, passions and emotions, and even ordinary occupations, were all personified as deities, so that scarcely a feeling or action was left without some divinity who was supposed to regulate it. It would seem too that the general doctrine of the divine government and protection has not been sufficient to satisfy mankind: they seem to want to have the deity brought nearer to them, and therefore nearly every religion presents us with a class of beings intermediate between God and man, under whose immediate care the latter are placed, and thus we get guardian deities of countries, cities, families, individuals, and classes. The next step is the bringing these divinities into closer connection with the senses by adopting some material object to represent them, either a symbolical image, a statue, or picture in the form of man, or even a living animal. This is the general character of the religious systems which existed from the first beginning of idolatry to the period when Christianity became widely diffused (excepting of course the Jewish religion), and which still exists among most of the nations which have not received either the Christian or Mohammedan faith. In nearly all such systems we find especial honours paid to the reproductive powers of nature, which are often worshipped under the grossest forms, as, for example, in the Hindu religion, and in the worship of Baal and Ashtaroth among the Phœnicians, and of Dionysus among the Greeks. In religions which teach a plurality of gods, the deities are generally represented as being more or less in a state of opposition to each other. This feature has probably arisen from the apparent mutual opposition of some of the forces which are found at work in nature, and from the poetical representations of early mythologers. The ultimate effect of such views of the divine nature has been to invest the character of the deities with those attributes of virtue and vice which belong to man, leaving the former only superior to the latter in their greater power and more lengthened existence. As a general principle, we find that the views which all nations take of the divine character bear a close analogy to the light in which they regard the phenomena of nature.

In most religions the existence of evil in the world is traced to the malignant efforts of a bad Being, who is viewed either as permitted to do evil for a time, with a view to the ultimate accomplishment of greater good, or as being independent in his origin and power of the good divinity, or even as so powerful that some nations have sought to appease him by divine honours.

Those religions which are based upon the doctrine of the unity of the deity, are chiefly distinguished from the polytheistic systems by their regarding the divine nature as utterly distinct from all material existences, and as incapable of being represented in any way by means of sensible objects. Hence the Jewish and Christian and Mohammedan religions are irreconcileably opposed to all forms of idolatry.

The different views which are taken of human duty and responsibility, and of the future state of existence, are generally found to depend upon the light in which the deity is regarded. It is not to be expected that men should measure their conduct by the standard of a purer morality than is furnished by the characters of their gods. Accordingly we find in all nations whose religion is polytheistic, that their positive morality has been low, and that their belief in an equitable divine government and in a future state of retribution has been most confused and vague. It is in Christianity alone that we find a code of morals based on the principle of universal love, and a clear announcement of a future state of rewards and punishments.

With regard to the doctrine of satisfaction for sin, we find in most nations some traces of the belief that 'without shedding of blood there is no remission;' and, as a consequence of this belief, the practice of propitiating the deity by sacrifice. In no religion however, except Christianity, do we find any clear or consistent doctrine of the means by which an atonement is provided, and of the course through which individuals must pass to secure the benefits of that atonement. [ATONEMENT.]

In their influence upon the social system, all religions, except Christianity, appear to have failed in producing that spirit of self-restraint and benevolence which is the best security for the peace and prosperity of any community. But in instituting a comparison on this point, we must not judge by the state of things existing in any community which *professes* a certain religion, but we must inquire whether in that community the religion in question exists in a genuine form, as determined by the documents in which its principles are embodied, or by any other test of acknowledged authority. If, for example, there exist any sacred books in which all the professors of any religion appeal as containing the tenets of their religion, we must first refer to them to test the purity of the religious system of a community, before we judge of the influence of that system on society. Tried by this test, we believe it will be found that Christianity, in proportion to the purity in which it has existed in any nation, has tended to produce peace and contentment, benevolence and industry, submission to the authority of the law, and regard for the rights of every class and individual, to an extent never approached by any nation professing a different religion. But, whatever views may be entertained of the respective powers of different religions in keeping a social system together, this fact at least seems established by evidence, that this object cannot be effected without some religion. All great legislators have used religion as the great bond of their institutions, and instances are frequent in history in which religious considerations have been the means of accomplishing or frustrating great political objects. Of the converse experiment we are almost without an example. But it is very probable that the anarchy of the French 'Reign of Terror,' in which the social system was for a time dissolved, had its chief cause in the general prevalence of infidel sentiments among the people.

The limits of this article will not allow of a detailed examination and comparison of the tenets of different religions. An account of the religions of the principal nations of the world will be found under their respective articles. To those articles the reader is referred for the facts by which he may judge of the opinions which are here expressed.

REMAINDER. An estate in remainder is defined by Coke to be 'a remnant of an estate in lands or tenements, expectant on a particular estate, created together with the same at one time.' According to this definition it must be an estate in lands or tenements, including incorporeal hereditaments, as rents and tithes; and it is an estate which at the time of its creation is not an estate in possession, but an estate the enjoyment of which is deferred. The estate in remainder may exist in lands or hereditaments held for an estate of inheritance or for life. It must be created at the same time with the preceding estate, and by the same instrument; but a will and a codicil are for this purpose the same instrument. A remainder may be limited by appointment, which is an execution of a power created by the instrument that creates the particular estate; for the instrument of appointment is legally considered as a part of the original instrument. A remainder may also be created either by deed or by will; and either according to the rules of the common law, or by the operation of the Statute of Uses, which is now the more usual means.

If a man seised in fee simple grants lands to A. for years or for life, and then to B and his heirs, B has the remainder in fee, which is a present interest or estate, and he has consequently a present right to the enjoyment of the lands upon the determination of A's estate; or, in other words, he has a vested estate, which is called a vested remainder. A reversion differs from a remainder in several respects. He who grants an estate or estates out of his own estate, retains as his reversion whatever he does not grant; and upon the determination of the estate or estates which he has granted, the land reverts to him. There may be several remainders and a reversion expectant on them. If A, tenant in fee simple, limits his estate to B for years, with remainder to C for life, with remainder to D in tail, this limitation does not exhaust the estate in fee simple. By the limitation B becomes tenant in possession for years, C has a vested remainder for life, D a vested remainder in tail, and A has the reversion in fee. If the limitation by A exhausts the whole estate, as it would have done in the preceding instance if the limitation had been to C and his heirs, A has no estate left. It is a necessary consequence that if a man grants all his estate, he can grant nothing more; and therefore the grant of any estate after an estate in fee simple is void as a remainder. Indeed the word remainder implies that what is granted as such is either a part or the whole of something which still remains of the original estate.

The estate which precedes the estate in remainder or in reversion is called the *particular* estate, being a particula or portion of all the estate which is limited; and the particular estate may be any estate except an estate at will, and an estate in fee simple. It must therefore be either an estate for years, or for life, or in tail.

Estates for years may be granted to commence at a future time; but by the rules of the common law, no estate of freehold can be created to commence at a future time. If therefore such an estate of freehold is granted, there must be created at the same time an estate for years, which shall continue till the time fixed for the enjoyment of the estate of freehold. If a freehold remainder expectant on an estate for years is created at common law, there must be livery of seisin to the tenant for years, for it is necessary that the freehold should pass to the grantee at the time of the grant, and the livery to the tenant for years enures to give a seisin to him to whom the estate of freehold is granted.

A remainder cannot be granted so as not to take effect immediately on the determination of the particular estate. If there is any interval left between the particular estate and the remainder in their creation, the remainder is absolutely void. A grant of an estate to A, and one day after the determination thereof to B, is a void remainder.

Estates in remainder are either vested or contingent. The remainder may vest, at the time of the limitation, or it may vest afterwards: in either case the remainder-man acquires an estate in the land, to the enjoyment of which he is entitled upon the determination of the preceding estate. But it may happen that a vested remainder may never become an estate in possession.

A vested remainder is an estate which, by the terms of the original limitation or conveyance, is limited or conveyed unconditionally. If a remainder is not vested, it is contingent.

A contingent remainder is defined by Fearne to be 'a remainder limited so as to depend on an event or condition which may never happen or be performed, or which may not happen or be performed till after the determination of the preceding estate.' Accordingly it is the limitation of the remainder which is conditional, and there is no remainder limited or given until the condition happens or is performed. The uncertainty of the remainder becoming an estate in possession is no part of the notion of a contingent remainder; for this kind of uncertainty may exist, as already observed, in the case of vested remainders.

Fearne has made four classes of contingent remainders, to some one of which he considers that all kinds of contingent remainders may be reduced, but he adds that 'several cases which fall literally under one or other of the two last of those four descriptions, are nevertheless ranked among vested estates.'

The first class is, 'where the remainder depends entirely on a contingent determination of the preceding estate itself;' or, as it may be explained, where a remainder is limited to take effect only on the happening of a specified contingent event which is to determine the preceding estate, and is not to take effect if the preceding estate determines in any other way. An example usually given is the following. A makes a feoffment to the use of B till C returns from Rome, and after C's return, then to D in fee. In this case B has an estate which will determine either upon C's return from Rome or by his own death; but the remainder is limited to D only upon the happening of a specified event which may never happen; and if B's estate determine by his death, or by forfeiture, which is possible, no estate is limited to D. There is then no limitation to D, except conditionally, and his estate is therefore contingent.

The second class is, 'where some uncertain event, unconnected with and collateral to the determination of the preceding estate, is by the nature of the limitation to precede the remainder.' This class is easily distinguished from the first, by the circumstance that the uncertain event upon which the remainder is limited, is entirely independent of the manner in which the preceding estate may or must determine. The following is an example: If a grant is made to A for life, remainder to B for life, and if B die before A, remainder to C for life, the uncertain event of B's dying before A is quite independent of the determination of A's estate, but the limitation of C's estate depends on this uncertain event happening.

In both these classes of remainders, the event on which the remainder is to take effect is absolutely uncertain; in the two following classes, the events on which the remainders are limited are events which certainly must happen, and the contingency arises from the uncertainty of the time when they will happen.

The third class is, 'where a remainder is limited to take effect upon an event, which, though it certainly must happen some time or other, yet may not happen till after the determination of the particular estate.' The following is an example:—a grant is made to J. S. for life, and after the death of J. D. the lands to remain to another in fee. Though it is certain that J. D. must die, this event, upon which the limitation in fee is to take effect, may not happen till after the determination of the life estate of J. S.

The fourth class is, 'where a remainder is limited to a person not ascertained, or not in being at the time when such limitation is made.' The following is an example:—a grant is made to A for life, remainder to the right heirs of J. S. Now as J. S. can have no heir till he is dead, and as he may not die till after the determination of the particular estate, such remainder is contingent. If an estate is limited to two persons for life, with remainder in fee to the survivor, the remainder is contingent, because it is uncertain which will be the survivor.

The first class of remainders mentioned by Fearne has sometimes been confounded with cases of conditional or contingent limitations, which, though not valid in conveyances at common law, are valid within certain limits in wills and in conveyances under the Statute of Uses. The distinction between the two things may be somewhat difficult to apprehend, but still there is a substantial distinction.

In the first class of remainders, the estate in remainder is limited to take effect as a remainder upon a determination of the preceding estate according to the original limitation: it does not defeat or abridge the preceding estate, but it is limited to commence when the preceding estate determines by the happening of that contingency which is originally declared to be a limit of its duration. In the case of conditional limitations, the event on which the conditional limitation is to take effect is an event independent of the measure of the previous estate, which measure is precisely ascertained by the terms of the original limitation. In the case of a contingent remainder, the second limitation takes effect as being a remnant which exists, and is capable of being limited over upon the contingent event taking place. If the first estate be limited in fee, as a limitation to the use of A and his heirs till C returns from Rome, and after the return of C, to the use of B in fee, this limitation to B cannot be a remainder, because the whole estate has been already limited, and there is nothing left to limit over. If the limitation is to A for life, and if C return from Rome, then to B in fee, the life estate of A may be defeated by the return of C, in which event B's estate commences, and is not merely a remnant limited on the expiration of A's life estate, but it comprises part of the estate limited to A: it is therefore not a remainder according to the definition. Both these are cases of conditional limitation, by which an estate of a definite measure is limited, and upon the happening of some event which in no way affects the original measure of the preceding estate, that estate is to determine before its regular determination according to the original limitation, and the estate so conditionally limited is to take effect in possession. It follows from what has been said, that a remainder cannot take effect at common law so as to defeat or abridge the particular estate: a limitation having that effect would not be a remainder, but if limited at common law would be void; and if limited by a will or by a conveyance to uses, it would take effect in another way.

The exception to the third class of contingent remainders is of this kind. The event on which the remainder is limited over, is an event which must happen some time, and may happen after the determination of the particular estate: the remainder is therefore strictly contingent. But if the probability of the event happening after the determination of the particular estate is very small, the remainder is held to be vested. The following is an example:—a limitation to A for eighty years, if B shall so long live; and after the death of B, to C in fee. In this case B, a person in being, may outlive the utmost limit of A's estate (eighty years); but the probability of this event is very small, and accordingly C's estate is held to be vested.

The numerous exceptions to the fourth class of contingent remainders are comprehended in what is called the Rule in Shelley's case, of which a complete exposition is given in Fearne's 'Essay on Contingent Remainders;' and in Preston's 'Treatise on Estates' (vol. i.). The nature of this rule may be generally stated as follows:—If lands are limited, either by deed or will, to a man for life, and after his death to his heirs or the heirs of his body, the limitation to the heirs would appear to be a contingent remainder according to the definition of the fourth class of contingent remainders, for the heirs are persons who cannot be ascertained till the death of the person to whom the estate for life is given. But it is an old rule of law that the estate so limited to the heirs or the heirs of the body takes immediate effect as an estate in the ancestor, and therefore, in the former case, A takes an estate of freehold with a vested remainder in fee. His life estate is consequently merged in his remainder in fee, and he becomes tenant in fee simple in possession. If an estate for life, or an estate tail, is interposed between the estate for life to the ancestor and the remainder to his heirs or the heirs of his body, still this remainder is vested in the ancestor, just in the same way as if it were limited to him and his heirs, or to him and the heirs of his body. Thus when A takes an estate for life, remainder to B for life, remainder to C in tail, remainder to the right heirs of A; this ultimate remainder is a vested remainder in fee in A, and, after his death and the determination of the intermediate estates, his heir will take by descent. But cases within this rule are not so properly exceptions, as cases which by the operation of the rule are excluded from the fourth class of contingent remainders.

There is another exception to the fourth class, which is allowed in devises, where it can be clearly inferred from the particular expressions in the will, that a limitation to the heir special of a person then living is intended as a designation of a particular person. In such case the remainder will vest; for the conclusion is not that the testator intended to limit the estate by way of contingent remainder to such person as should be ascertained to be heir by the death of his ancestor, but that he intended by the word 'heir,' accompanied with the other expressions in the will, to designate a particular person.

The following is an apparent exception to the first class of contingent remainders. In settlements lands are often limited to the use of A for life, and after the determination of that estate by forfeiture or otherwise in his lifetime, to the use of B and his heirs during the life of A, in trust for A, and to preserve the contingent remainders; and after the death of A, to the use of the first and other sons of A successively in tail male, &c. This estate to the use of B and his heirs during the life of A is the estate given to trustees to support the subsequent contingent limitations; and in order that such estate to B and his heirs may be sufficient for the purpose, it must be vested. Accordingly it has long been held that this limitation gives the trustees a vested freehold estate, which will therefore support the contingent remainders. The reason given by Fearne for this estate being vested is, that the trustees have a present capacity to take the estate whenever it becomes vacant. He observes, 'The present capacity of taking effect in possession if the possession were to become vacant, and not the certainty that the possession will become vacant before the estate limited in remainder determines, universally distinguishes a vested remainder from one that is contingent.' (p. 216.)

If we adopt this test, it is clear that the limitation to trustees to preserve contingent remainders is not a limitation of that kind which is included in the first class of contingent remainders, for the limitations in remainder of that class are to take effect as limitations only on the happening of a specified contingent event which determines the preceding estate, and not on the happening of other events which may or must determine the preceding estate. If then a limitation over is to take effect on the happening of an uncertain event, and not on the happening of any other event, there is nothing limited as a remainder till the uncertain event has happened. But the estate to the trustees is so given as to take effect as a limitation upon any event happening which shall determine the estate of A in his lifetime. There is therefore a clear distinction between the two cases as to the capacity of taking effect in possession. But this capacity of taking effect in possession whenever the preceding estate becomes vacant, can hardly be used as a means of ascertaining whether the trustees have a vested estate. An estate is vested when there is either a present right of present enjoyment or a present right to a future enjoyment. A vested remainder is not the former, but it is the latter; the right is ascertained and the enjoyment is merely deferred. But the present right to a future enjoyment is a present capacity to enjoy whenever the time for enjoyment comes. Therefore a present capacity to enjoy if the possession become vacant is a vested remainder, and a vested remainder is a present capacity to enjoy if the possession becomes vacant; but whether in a given case such present capacity or such vested remainder (which is the same thing) actually exists, is the matter to be determined. The rule then which is to be the test whether a remainder is vested or contingent, is merely a description of a vested remainder in other and equivalent words; and the conclusion is that a remainder is vested and not contingent when it is vested. Now, as the very notion of a contingent as distinguished from a vested remainder depends upon the limitation of the remainder being conditional or unconditional, it follows that there is no test of a contingent as distinguished from a vested remainder, except by means of the words in which the limitation of the remainder is expressed.

An estate to A for life, with remainder to B during the life of A, would be a void remainder, but for the legal possibility of A's estate being forfeited or surrendered in his lifetime. This legal possibility is also considered as one of the regular modes in which A's estate may determine, that is, as one of the modes by which it is liable to determine according to the nature of the original limitation. For if it is not so considered, the estate to B is in the nature of a conditional limitation. Now, an estate might be limited upon the determination of A's life estate by forfeiture or otherwise in his lifetime, either for the period of A's life, or for a longer period than A's life, as for instance to B and his heirs. But such a limitation to B and his heirs is in the form of a contingent remainder, for by the terms of the limitation it is made upon a condition which may never be fulfilled; and there is a mode by which A's estate must determine, namely, his death, in which event nothing is limited to B and his heirs. If the estate to B and his heirs were limited upon any determination of A's estate in his lifetime, or upon the death of A, it would be a vested remainder, for it would be limited in all events, and therefore not conditionally limited. Now, the estate to the trustees to preserve contingent remainders during the life of A, only differs from such last-mentioned limitation in not containing any limitation upon the event of A's death. But a limitation to the trustees upon the event of A's death is unnecessary for the purpose of giving a vested remainder, because the estate limited to the trustees determines with A's life. There is therefore no contingent event upon which the estate to the trustees during the life of A is limited, but it is limited in all events, that is, unconditionally, and therefore it is not a contingent remainder.

A difficulty arises from the form of the words in which the limitation is made, for the estate is limited upon the determination, &c. of A's estate, and those words apparently express a condition. But these words in themselves are not words of condition, any more than a limitation to A for life, and upon his death to B and his heirs. They merely denote the events on the happening of which the estate is to take effect in possession. The events which are to determine the life estate of A, and upon which the limitation over is made, are not extrinsic events, such as the return of B from Rome. A limitation over on the event of B's returning from Rome would be a conditional limitation to defeat A's life estate. But the events on which A's life estate may determine before his death, are events to which such an estate is incident; and these events may fix its measure, as well as the death of A. The estate to the trustees for the life of A is therefore clearly an estate analogous in its limitation to an estate limited over on the death of A; the only difference being that A's death is an event that must happen, and the forfeiture, &c. are events which may happen. An estate limited over by way of remainder upon the happening of any of all the events by which the previous estate may determine, is clearly not a contingent remainder within any of the four classes defined by Fearne. But the estate to the trustees and their heirs generally, upon the determination of A's estate in his lifetime by forfeiture or otherwise, without adding 'during the life of A,' is clearly conditional; for by the terms of the limitation nothing is limited to the trustees except in the event of A's estate determining in certain ways in which it may determine, and nothing is limited in the event of its determining by his death, an event that must happen. It is not the words, 'upon the determination of A's estate by forfeiture or otherwise in his lifetime,' which make the estate to the trustees and their heirs generally a limitation of a remainder upon a condition; but it is the circumstance of their estate being for a longer period than the life of A, and nothing being limited to them on the event of A's estate determining by his death, which renders the limitation conditional. This kind of contingent remainder is however hardly included in Fearne's first class; and it seems to form a fifth class of contingent remainders.

An estate similar to the estate to trustees to preserve contingent remainders occurs in the ordinary limitations to uses to bar dower in purchase-deeds, where, after the limitation to the purchaser for his life, and before the limitation of the fee, an estate is interposed to a trustee and his heirs during the life of the purchaser: the object being, by the interposition of a vested freehold remainder, to prevent the purchaser from taking such estate as will entitle his wife to dower. The like observations apply to this estate of the trustee to bar dower as to the estate of the trustees to preserve contingent remainders. This further observation applies to both estates: they fail to become estates in possession not from any contingency attached to their limitation either in words or substance, but because the estates themselves expire before or at the same moment with the particular estate, a circumstance which never prevents a remainder from vesting. Thus, a limitation to A for life with remainder to B for life, gives B a vested remainder; and even if the limitation to B were expressly made 'in case he shall survive A,' still the remainder to B would be vested. The reason of this appears to be, that notwithstanding the words of contingency, there is no real contingency attached to the remainder except that of its possible determination before the particular estate. The force of this observation will appear when it is considered that a limitation to A for life with remainder to B and his heirs in case he shall survive A, gives a contingent remainder to B, while, as already observed, a limitation to A for life with remainder to B for life in case he shall survive A, gives a vested remainder to B.

The importance of this subject must be an apology for these remarks. The limitation to the trustees to preserve contingent remainders may, owing to carelessness or other causes, be expressed in terms different from what it ought to be. Thus the limitation might be to the trustees and their heirs upon the determination of A's life estate by forfeiture or otherwise *in his lifetime*, without the words 'during the life of A;' or it might be to the trustees and their heirs upon the determination of A's life estate by forfeiture or otherwise, without the words 'during the life of A.' In the former case the limitation would be contingent; in the latter a vested remainder in fee would pass to the trustees and their heirs: in both cases the object of the settlement might fail to be secured.*

A contingent remainder may intervene between the particular estate and other limitations over, and yet the subsequent limitations may be vested, if made to a person *in esse*, provided the contingent limitation is not in fee simple. The contingent remainder itself may also vest, and then become an estate interposed between the particular estate and the subsequent vested limitations, if the contingency happens during the existence of the particular estate. If in the same conveyance an estate is limited to A for life, followed by a contingent remainder and a subsequent limitation to A and his heirs, or A and the heirs of his body, this last limitation, though executed under the rule in Shelley's case, is still so executed as to allow the contingent remainder to interpose as a vested estate when the contingency happens. A subsequent contingent limitation may vest before a preceding one, but it follows from what has been said that the preceding one is still capable of vesting.

Lands may be so limited as to be subject to a general power of appointment. In such cases, the general power of appointment will not prevent the estates limited in default of appointment from vesting; though the due exercise of the power will divest them.

Certain cases in which a remainder is limited upon a contingency which affects the preceding estate, but does not affect the ulterior limitations, are discussed by Fearne (p. 233). The same section (x.) contains remarks on limitation which seem to import a contingency, but in fact only denote the time when the remainder is to vest in possession. These remarks seem to be applicable to the case of the trustees to preserve contingent remainders to whom an estate is limited during the life of the tenant for life, though this application of them is not made by Fearne.

A contingent remainder may be limited generally upon any event, except in such cases as the following:—the contingent event being illegal; the remote possibility of the contingent event; and the condition enuring to defeat the preceding estate. These subjects are fully discussed by Fearne (c. 2).

It will be collected from what has been said that a contingent remainder of freehold must be preceded by a vested estate of freehold; for if there is no precedent vested estate of freehold, and the freehold remainder is contingent, the freehold either remains in the grantor, and therefore is not transferred to any one else, or it is transferred in some remainder which is limited after the contingent remainder, and which, being therefore vested in possession, precludes all possibility of the vesting of the contingent estate, which by the terms of the limitation must precede it. This rule as to the necessity of a vested freehold estate to support a contingent remainder, applies both to limitations of uses and of estates limited at common law. If the contingent remainder be for years, there is no necessity for a preceding freehold estate to support it: and when the legal estate is vested in trustees in trust, such legal estate in the trustees renders it unnecessary that a contingent remainder should vest during the continuance or at the expiration of the preceding limitation in trust.

It will also appear from the definitions of contingent remainders that they must vest, that is, the conditions on which they are limited must be fulfilled, during the continuance of the particular estate or immediately on its determination. One of the cases in which such remainders were formerly liable to fail under the fourth class of contingent remainders, was in the case of such limitations as to A for life, and to his first and other sons in tail. Originally a posthumous son could not take, but such child is now for this and several other purposes considered as a person *in esse* during the period of pregnancy. When a contingent remainder is limited to several in a conveyance to uses or by a devise, such remainder will vest in the first person in whom it can vest, but it will divest in due proportions in favour of other persons who are included in the limitations, and who become capable of taking before the determination of the particular estate; and such persons may take as joint tenants, though their estates vest at different times.

Any determination of the particular estate before a legal remainder vests, must, consistently with what has been said, destroy the contingent remainder. The contingent remainder may fail not only through the contingency not happening till after the expiration of the particular estate, but through its destruction by the surrender of the tenant for life, or by the forfeiture of his estate during the existence of the contingency. The intermediate contingent remainder will also be destroyed if the particular estate and the next vested estate of freehold become united by the conveyance or act of the parties, so that the particular estate be merged. This however is not the case when the particular estate with a contingent remainder over and the inheritance are limited by the same instrument, for though the estate and the inheritance is executed, this does not prevent the contingent remainder from vesting upon the happening of the condition on which it depends.

A contingent remainder of an estate of inheritance is descendible to the heirs of an ascertained person to whom it is limited, if such person should die before the contingency happens, and it will vest if the same should happen during the continuance of the particular estate. Contingent remainders were once not considered devisable, but it was afterwards determined that they were devisable whenever they were descendible to the heirs of the persons to whom they were limited; and under the recent statute (1 Vic., c. 26), they are devisable in common with all contingent, executory, or other future interests in any real or personal estate.

Contingent remainders are not assignable at law, though capable of being bound by a contract in equity. They were also capable of being bound by a fine by way of estoppel. By the Irish Act for the abolition of fines and recoveries there is a provision for the assignment at law of contingent estates. There is no corresponding provision in the English act: and as fines are abolished, and a contingent estate is confessedly incapable of being dealt with at law, and a married woman is incapable of contracting, a doubt (perhaps not well founded) exists whether a deed acknowledged by a married woman will bind her contingent remainder even in equity.

Though a fee cannot be limited after a fee as a remainder, two or more contingent fees may be limited in the alternative so that one only shall take effect.

Interests in chattels real and personal are susceptible of limitations over after the limitation of some partial interest in them; but from the nature of those interests they are not capable of such extensive modifications as freehold interests in land, and they cannot be operated upon by the Statute of Uses. Originally a bequest of a term of years to a man for life was an absolute gift of the whole term, and the devisee might dispose of the whole interest as he pleased; but at present a bequest of such term to A for life, and after his death to B, is a bequest of the whole term to A, subject to an executory bequest to B, to take effect if A dies before the expiration of the term. It is not a particular estate to A for life and a remainder to B. Any disposition of a chattel

* For this suggestion as to the nature of the estate limited to the trustees and their heirs without the words 'during the life of A,' and for other valuable remarks, the writer is indebted to a learned friend.

tail, which in the case of lands would make an estate tail, passes the whole interest. Thus if the second bequest of the term of years were to B and the heirs of his body, B would take the whole interest.

An executory devise is such a limitation of a future estate in lands, and an executory bequest is such a limitation of a future interest in chattels, as are allowed in the case of a will, though not in conveyances at common law. Accordingly a fee may be limited after a fee in a will or by way of use upon contingencies which may happen within certain limits of time; and such limitations take effect as executory devises or springing or shifting uses. But when future estates are so limited by devise as to be comprehended within the rules which apply to contingent remainders, they will be considered as such, and not as executory devises.

The subject of contingent remainders is fully discussed in the elaborate Essay of Fearne on *Contingent Remainders and Executory Devises*; see also Hayes, *On Conveyancing*, Appendix.)

REMAINS, ORGANIC. [ORGANIC REMAINS.]

REMBRANDT, PAUL GERRETZ, commonly called Rembrandt van Ryn, or Rhyn, was the son of Hermann Gerretz, a miller. He was born in 1606, in his father's mill on the banks of the Rhine near Leyden, whence the agnomen van Ryn. When very young he was sent to a Latin school at Leyden, but he showed such a distaste for learning, that his father gave up the idea of making a scholar of him, and consented to his becoming a painter, as he had manifested a decided talent for it. Young Rembrandt was accordingly placed first with Jacob van Zwanenburg, or, according to another account, George Schooten. He remained with his first master about three years. He then studied for a short time under Peter Lastmann at Amsterdam, and lastly, for a short time, under Jacob Pinas. From these masters Rembrandt could have learnt nothing more than the mere mechanical part of his art, for both his taste and his style were peculiarly his own. After leaving Pinas, he returned to his father's mill, where he commenced painting, taking the immediate vicinity and the peasants of the neighbourhood as his standard of nature, and applying himself enthusiastically to his work. He had not finished many pieces before he was considered as a prodigy by his friends, and he was persuaded by them to take one of these early productions to a dealer in the Hague, who, to his no greater joy than astonishment, gave him 100 florins (about eight guineas) for his performance. Rembrandt was so elated with this unexpected good fortune, that he posted home to his father in a chariot to convey the joyful intelligence. From this time he rapidly acquired both fame and fortune. In 1630 he settled in Amsterdam, where he resided the remainder of his life, and shortly afterwards married a handsome peasant-girl of Ransdorf, whose portrait he has often painted. His reputation now became so great that he had many scholars, each of whom paid him annually 100 florins, and he so arranged their studies as to make them as profitable as possible to himself; he retouched the copies which they made from his own works, and sold them as originals.

This rapid and unexpected good fortune appears to have engendered in Rembrandt a love of money, and avarice became his ruling passion: he resorted to various mean expedients for acquiring wealth; he sold impressions of his etchings, which were the principal source of his income, before they were finished, when finished, and afterwards with slight alterations; and such was the rage after his works, that collectors thought it incumbent upon them to possess impressions of his various etchings in all their different stages, and he is said to have thrown off from some plates even as many as seven proofs, all varying but very slightly. He also circulated reports that he was going to leave the country, and thus created large demands for his etchings. Various other much more absurd and not less mean practices are reported of him; they were worthy of the low taste of Rembrandt, for he could endure no restraint upon his manners or his conversation; polite society was to him intolerable, and he always avoided it.

The burgomaster Six was the only man of rank with whom Rembrandt associated, and with him he occasionally passed a few days in his house in the vicinity of Amsterdam, in which the burgomaster had fitted up a painting-room for him. The history of the celebrated print, the landscape De la Moutarde, which was etched in this house, is curious. Rembrandt could not relish his boiled beef without mustard; but it happened upon one occasion that there was none in the house; and the burgomaster, desirous of pleasing his guest, immediately sent off one of his servants in haste to the city to procure some. Rembrandt, observing that he was rather a phlegmatic-looking person, offered to bet that he would make an etching before the man returned. The wager was immediately accepted, and Rembrandt forthwith, having taken a prepared plate, commenced to etch the landscape from the burgomaster's window, comprising a view of Amsterdam, which he finished in his happiest style with that vigour and lightness of touch peculiar to him, just before the servant arrived with the mustard; hence it was called the landscape De la Moutarde. Although it is little more than a mere foreground, an original impression from this plate is worth from thirty to forty guineas.

According to Sandrart, Rembrandt realised an annual income of nearly 2500 florins (about 200*l.*) from the sale of the copies made from his works by his pupils, and the traffic in his etchings alone, independent of the labours of his own pencil and his pupils' fees; a large amount of itself, but which added to the rest must have made a princely income for those times. He considered that he conferred a favour which he disposed of impressions of some of his plates. The celebrated print of Christ healing the Sick, commonly called the Hundred Guilders, received its denomination from the fact that he refused to sell it for less than that amount—about eight guineas. This plate was bought by Alderman Boydell, who destroyed it after he had taken a few impressions from it, which enhanced the value of the prints accordingly. A good impression is worth from fifty to sixty guineas.

Rembrandt's best etchings realise enormous prices, both the portraits and the historical pieces varying from thirty to a hundred guineas. The most remarkable portraits are those of the burgomaster Six; Van Coppenol, the writing-master; Van Thol, the advocate; Uytenbogaert, the minister, and Uytenbogaert, the gold-weigher.

Rembrandt's great power was portrait; his pictures of that class are in the mass incomparably superior to his historical pieces. The evident cause of this was his utter want of taste in design, which, with rare exceptions, is decidedly the most vulgar of any artist's who has ever earned himself a name. Instead of acquiring fame in the ordinary way by any merits or beauties of form, Rembrandt commanded it, in spite of drawing the most gross and incorrect, through a rich and brilliant colouring, a consummate mastery of chiaroscuro, and not unfrequently a power of composition that has seldom been surpassed. He was, as Fuseli has remarked, 'a genius of the first class in whatever relates not to form. In spite of the most portentous deformity, and without considering the spell of his chiaroscuro, such were his powers of nature, such the grandeur, pathos, or simplicity of his composition, from the most elevated or extensive arrangement to the meanest and most homely, that the best cultivated eye, the purest sensibility, and the most refined taste dwell on them, equally enthralled. He possessed the full empire of light and shade, and of all the tints that float between them. None ever like Rembrandt knew how to improve an accident into a beauty, or give importance to a trifle.' (*Lecture II.*)

Rembrandt is supposed to have acquired his peculiar taste for a brilliant concentration of light from an appearance that he had been familiar with from his infancy in his father's mill, where a strong beam of light coming from a small and lofty aperture cast on the surrounding objects that peculiar tone which we see so happily illustrated in his pictures. He arranged the light in his own painting-room upon similar principles, and generally fixed a drapery behind his sitter of such colour as he intended to paint the ground.

Rembrandt had a contempt for the antique; and the ordinary cant of connoisseurs about grace, sublimity, and grandeur only excited his ridicule. His antiques, as he used to call them, were some old pieces of armour, unique weapons, curious turbans, and various antiquated articles of dress, which he procured from Polish Jews, and with which he indiscriminately clothed individuals of all nations, antient and modern. He once showed one of his performances to Vandyck, who praised the picture considerably; upon which Rembrandt, with a certain degree of satisfaction and consequence, said, 'Yet I have never been in Italy;' 'That's very evident,' returned Vandyck.

Rembrandt's taste led him to imitate certain effects of nature, and in the truth and power with which he gave these effects, both in his paintings and his etchings, he has seldom been equalled, and never surpassed. The prevailing light of his portraits is that of a brilliant sunset, and a rich golden tone of colouring pervades all his works. His originality is perhaps still more conspicuous in his etchings than in his paintings; he exhibited powers of the etching-needle before unknown; many of his plates are prodigies of chiaroscuro; and there is a softness and reality about them which we look for in vain in the works of other masters. It is said that he made a great secret of his mode of etching, and never allowed any one to see him at work. Most of his more important plates have evident traces of the dry point.

Rembrandt, at the beginning of his career, bestowed great labour on his pictures, and, in the manner of the generality of the Dutch painters, wrought them up to a very high finish. The Woman taken in Adultery, in the National Gallery, is probably his best picture in this style. At a later period of life his whole attention was given to the effect, and his pictures, although still greatly laboured, had the appearance of having been executed with a remarkable freedom and boldness of touch: this is particularly the case with his portraits, some of which have an astonishing body of colour in the lights. When this roughness was objected to by any one, he was in the habit of saying that he was a painter, not a dyer; and when visitors ventured to examine his pictures too closely, he used to tell them that the smell of paint was unwholesome.

Rembrandt died in Amsterdam, 1674. He had one son, Titus, who inherited his property, which, according to Descamps, was considerable. Titus was the pupil of his father, but being Rembrandt's son was the only distinction he ever enjoyed. Original Rembrandts are very valuable; some are estimated at several thousand pounds. They are scattered all over Europe, and this country possesses many; those in the National Gallery are all particularly fine specimens: the Gallery of Dresden also possesses several of his master-pieces.

A complete descriptive catalogue of his works was published by D. Daulby, in Liverpool, 1796; another, by A. Bartsch, in 1797, of Vienna; and a list of the principal of them is given in Bryan's *Dictionary of Painters*. The best notices of Rembrandt are those in the work by Descamps, entitled 'La Vie des Peintres Flamands,' &c., and Fiorillo's 'Geschichte der Zeichnenden Künste in Deutschland und den vereinigten Niederlanden.'

There is a fine collection of Rembrandt's etchings in the British Museum.

REMEMBRANCERS (*rememoratores*), formerly called clerks of the remembrance (37 Edw. III., c. 4), are officers of whom, until recently, there were three in the exchequer, called respectively the king's remembrancer, the lord treasurer's remembrancer, and the remembrancer of first fruits; their duty being to put the lord-treasurer and the barons of the exchequer, who are the judges of that court, in remembrance of such things as are to be called on and done for the king's benefit.

I. The office of the queen's remembrancer has relation to the proceedings of the court of exchequer in the exercise of its original jurisdiction as a court of revenue, and of its incidental jurisdiction as a court of equity, founded upon the fiction that the party seeking for relief upon matters of equity is a debtor and an accountant to the king, who by reason of the withholding of that to which he is equitably entitled, is the less able (quo minus sufficiens existit) to pay his debts to the crown. On the revenue side, the queen's remembrancer enters all the recognizances taken before the barons for any of the queen's debts, for appearances, &c., and he takes all bonds for such debts, and for the due execution of offices, and makes out process for breach of them; he also writes process against the collectors of customs, excise, and other public payments, for their accounts. Informations for intrusion into the queen's lands, and information for debts due to the crown, and on penal statutes, are entered and sued in his office; and he makes the bills of composition on penal laws. Indentures and other evidences which relate to the passing of any lands to or from the king are delivered into his office. At the beginning of Michaelmas term he reads in the court the oath taken by all the officers of the court upon admission. Writs of prerogative and writs of privilege for officers and ministers of the court are made out by him; and commissions of Nisi prius, her majesty's warrant, on trial of any matters within his office, commissions to find debts due to the crown, and writs of extent awarded in pursuance of 33 Hen. VIII., c. 39, are issued and prosecuted in this office: also general process for the recovery of arrears of taxes and other debts due to the crown, which issue twice a year. All differences as to irregularities in proceedings are determined by the queen's remembrancer, with power to give costs against the party in fault, but subject to an appeal to the court. (5 Rich. II st. 1, c. 15, 16; 13 and 14 Car. II., c. 21.)

On the equity side of the court the deputy-remembrancer performed till lately the same duties which in the court of chancery are performed by the accountant-general and the masters in chancery, but now the court of exchequer has the assistance of an accountant-general and masters in the exercise of its equitable jurisdiction. Under 57 Geo. III., c. 60, for regulating certain offices in the Court of Exchequer in England, the duties of the office of king's remembrancer, &c. are now discharged in person, and not, as formerly, by deputy. He is bound by a rule of court, Jac. II., to attend the court during its sittings, to answer inquiries respecting the course of proceedings, and to enter the rules and orders of the Court of Exchequer relating to its fiscal or its equitable jurisdiction, and he now executes the duties formerly performed by the lord-treasurer's remembrancer, now abolished by 3 and 4 Wm. IV., c. 99.

II. The lord-treasurer's remembrancer's office was the office principally concerned in matters relating to the landed and casual revenue of the crown. When the king's title was found by an inquest of office, it became the duty of the officer with whom the writ and inquisition remained, to send a transcript into the office, in order to being put in charge for the service of the crown; he issued process for debts to the king, and against sheriffs, escheators, &c. and others who did not account. He took the accounts of all sheriffs, and made the record, whereby it appeared whether sheriffs and other accountants paid their proffers, that is, the balances appearing upon their accounts, due at Easter and Michaelmas, and he made another record showing whether sheriffs and other accountants kept their days prefixed. There were also brought into his office all the accounts of customers, comptrollers, and accountants, which were to be entered on record.

All estreats of fines, issues, and amerciaments, set or imposed in any of the courts at Westminster, or at the assizes or sessions, were certified into his office, and by him delivered to the clerk of the estreats, to make out process on them; and he might issue process for discovery of tenures and all revenue due to the crown by reason thereof, &c. As soon as the estreats came into this office, the parties interested might appear and deny the king's right, upon which the pleadings between the crown and the claimant were carried on in this office according to the course of the common law; and the right was either determined by the court upon demurrer or by verdict of a jury. The pleadings and judgments were entered on rolls called the 'Memoranda' of each year. Those of the reign of Edw. I. were published by Serjeant Maynard, in the first volume of his edition of the Year-Books, amongst which appears a letter from the lieutenant-treasurer and barons to the king, setting out the singular proceeding of the Earl Marshal and the Earl of Hereford, who, on Thursday next before the feast of St. Bartholomew, 25 Edw. III., came into the Exchequer with many others, knights-bannerets and bachelors: 'And the Earl of Hereford said that he was charged to say, on behalf of the Earl Marshal and the others who were there, and of all the commonalty (or community) of the kingdom, as well clerks as lay, that of two things they felt themselves grieved: first, by some grievances, the articles of which they had shown to you, their liege lord; and the other, which they understood was done by us of the Exchequer, without your knowledge, in respect of the levying of the eighth (utigme) and the taking of wools. And they said that the writs which are issued for the levying of the eighth, it is contained, that earls, barons, knights, and the commonalty of the kingdom have granted the eighth, as they and their ancestors have heretofore done; whereas the eighth by them and the commonalty never was granted. And he said that *nothing reduces a man to bondage more than being taxed at will*, and that if the eighth were levied, it would turn to the disherison of them and their heirs. And he said openly, *and all the others afterwards*, that such tallage and such taking of wool *were not sufferable, nor would they in any manner suffer them*. And they prayed to that we should redress these things; whereupon they departed without waiting for any answer. Therefore, sire, be pleased to send us your will upon this matter.' The king answered from Westminster, 'As to this, that they would in no wise suffer the levying of the eighth, we will that you do not omit to proceed in taxing; but in as much as they said that the levying would turn to their disherison, &c., make known to the said earls that, in the taxation of the eighth, if there be any who doubt of such prejudice or disherison, the king shall acquit him by his sealed letters, that neither the taxation nor the levy be turned to the bondage of any one, or be drawn in use in times to come; but that the king may aid himself now for his great need, which is so urgent for the salvation of himself and themselves and of all the realm, and to lighten the mischief wherewith they have been long time charged. And that the chancellor shall make letters, &c. for those who doubt, &c. And as to the taking of the wools, that the ordinance made thereof be held, and that it be said everywhere by you and by those who intermeddle therewith, that the king will take nothing but by purchase making satisfaction, and that our intention never was otherwise, nor was the thing otherwise put in use.'

Pleadings in the lord treasurer's remembrancer's office have fallen very much into disuse since the alienation of crown lands and the abolition of military tenures by 12 Car. II., c. 24.

Parties may apply in a summary manner for the indulgence of the Court of Exchequer, which is empowered by privy seal, at the commencement of every reign, to compound or discharge any fines, issues, amercements, or recognizances, according to the circumstances of each case; and until the recent statute of 3 & 4 Will. IV., c. 99, such applications passed through this office. By that statute, the office of the lord treasurer's remembrancer was, with the offices connected therewith, abolished. Part of the duties of this office had been previously transferred to other offices, part ceased by the act, and the remainder are performed by the queen's remembrancer.

III. *The remembrancer of the First Fruits' office* receives the bishop's returns of institutions, takes all compositions and bonds for payment of first fruits and tenths, and makes process against all such persons as do not pay the same. (Cowell. *Report of Select Committee on Finance*, 1798.)

IV. *Remembrancer of the City of London.* The duties of this officer are those of agent for the corporation in parliament, and at the council and treasury boards. He gives a daily attendance at the houses of parliament during every session, to examine all bills and proceedings of the houses of lords and commons, and to report on such as may be likely to affect the interest or privileges of the city. For this purpose, the officers of both houses of parliament give him facilities of admission and attendance; and, for the purpose of identification by them, he sometimes wears a medal with the arms of the city. In this capacity he has to watch from 100 to 200 bills every year; and there are few years in which the corporation have not at least one bill of their own in progress. His duty is further to take the necessary steps to procure the presentation of all addresses and resolutions of the corporation to the king and queen and all the branches of the royal family; to make copies of the addresses and deliver the same, and to attend the sheriffs, when the appointment is made to receive the address or resolution, and the corporation, when the same is presented: to engross all petitions of the corporation to be presented to either house of parliament; to make and deliver copies, and to attend when the petitions are presented. If the petition be to the House of Lords, the remembrancer, with the sheriffs, waits on some peer of parliament, and requests him to present it. He has to give the city members and the sheriffs notice when petitions are to be presented to the House of Commons; to make applications for obtaining, and, when received, to distribute, the city tippets for duties on wine, an allowance made by the lords of the treasury, the origin of which is not known. The earliest entry of its being made is about the year 1256. The sum allowed is 100*l.* 16*s.*, which is distributed in different proportions amongst the lord mayor, aldermen, recorder, sheriffs, common-serjeant, chamberlain, town clerk, remembrancer, and sword-bearer. (*General Report on Municipal Corporations of England and Wales*, 1837.)

REMIREMONT. [Vosges.]

REMIPES. [Hippa.]

REMO, SAN. [San Remo.]

REMONSTRANTS. [Pelagians.]

REMY, ST., a town in France, in the department of Bouches du Rhône, 10 miles east of Tarascon. This town appears to occupy the site of the Roman town of Glanum, or, more fully, Glanum Livii, mentioned by Pliny, and in the 'Antonine Itinerary' and the Peutinger Table. It derives its modern name from St. Remy, bishop of Reims. [Rheims.] The town is situated in a marshy valley, and consists of some narrow streets, with irregularly-built houses. The public square is surrounded by buildings of a better class, and is adorned with a fountain; the town-hall, a good building, lately rebuilt, occupies one side of the square. The parish church has also been lately rebuilt. There are two remarkable Roman remains, a triumphal arch and a mausoleum. The triumphal arch has only one small archway, supported at the corners by square Doric pilasters, the capitals of which are the imposts of the arch. On each front of the structure, on each side of the arch, are two fluted Corinthian columns, which have lost their capitals and a portion of their shafts. In the four intercolumniar spaces are groups, each of two figures, touching the wall; but of the whole eight figures, only two retain their heads. The vault of the arch and the archivolt are richly ornamented with foliage and similar ornaments in relief. The date of this monument, and the person in whose honour it was erected, are unknown. The upper part is very much dilapidated, and has been covered in with a stone roof to prevent further decay. The mausoleum is in better preservation. It consists of three compartments, resting one upon the other, the whole supported by a square base of masonry, and rising to the height of more than fifty feet. The first compartment is a square of rather smaller dimensions than the base on which it rests: its four faces are adorned with sculptures in relief of human figures as large as life, engaged in combat, of tolerably good design: at the corners of this compartment are square pilasters, with capitals of a very grotesque character. The second compartment is also square, with an open arch on each side: the arches, adorned with ornamental sculpture, rest on pilasters without bases. The angles of this part of the building are supported by fluted pillars, with Corinthian capitals and an ornamented frieze. The third part is circular, and is composed of ten Corinthian columns fluted, with an ornamented frieze, supporting a small dome, so as to present the appearance of a small round temple. In it are two statues, now headless, which may be seen between the columns.

There are some other remains, the ruins of walls and a Roman road. A subterraneous aqueduct extends from near the town in the direction of Arles: it is vaulted, five feet high by two feet wide. Urns; medals of gold, silver, and copper; and inscriptions, have been found in considerable numbers.

The population of the commune of St. Remy was, in 1826, 5387; in 1831, 5454, of whom 3213 were in the town. Some silk is thrown, and trade is carried on in corn and wine. There are two yearly fairs. Marble is quarried in the neighbourhood. The town has a lunatic asylum.

RENAIX (in Flemish, *Ronse*) is a considerable town in the province of West Flanders, in the kingdom of Belgium, 20 miles south by west of Ghent, and 7 miles south of Oudenarde. It is a flourishing place, and (according to Cannabich, 1830) has above 12,000 inhabitants, who carry on extensive manufactures of woollens and hats, and have a great trade in those articles and in linen. The only public buildings of any importance are a magnificent château, three churches, and an hospital.

RENAUDOT, EUSE'BIUS, a learned writer on the ecclesiastical history and antiquities of the Eastern church, was born at Paris in 1646. His father was first physician to the dauphin of France (afterwards Louis XIV.). Renaudot was educated at the Jesuits' college, and entered the congregation of the Oratoire, though he did not remain long in it. From his early youth he was particularly inclined to the study of the Oriental languages, but chiefly of the Arabic, Syriac, and Coptic tongues, by means of which he was afterwards enabled to enter so deeply into the origin and history of the Eastern church. He became well known at court, where his vast learning made him much esteemed and admired. In this way he was brought to the notice of Colbert, who, being then desirous of establishing printing-presses for the Oriental languages at Paris, consulted him upon the subject, engaged his services and offered him the reversion of a place in the Royal Library; but that minister having died before his views could be realised, Renaudot was not appointed to the vacant office. He seems however to have been employed by the king in various important negotiations with the governments of England and Spain, his time being so much taken up by these occupations, that, while they lasted, he almost entirely discontinued his favourite studies. In the year 1689 he was made a member of the French Academy, and, three years after, of that of the 'Inscriptions et Belles-Lettres.' In 1700 he accompanied to Rome Cardinal de Noailles, archbishop of Paris, who had become his patron, and he acted as his *conclavista* in the conclave which elected Clement XI. to the papal dignity. While at Rome, Renaudot resumed his favourite studies, and the library of the Vatican furnished him with ample materials for the history of the Eastern church—a subject which he had long in mind, and to which he now devoted his whole attention. In this design he was assisted by the new pope, who persuaded him to remain in Rome several months after the departure of Cardinal de Noailles, and gave him the priory of Frossey in Bretagne. From Rome Renaudot went to Florence, where he was equally well received and entertained by the grand-duke, who caused him to be made a member of the Academy della Crusca. On his return to France, Renaudot devoted himself entirely to letters, and composed a great number of learned dissertations, which are printed in the Memoirs of the Academy. He died in 1720, at the age of 74, greatly regretted by the learned men of his time. His fine and extensive collection of Oriental manuscripts he bequeathed to the abbey of St. Germain des Prés. They remained there until the Revolution, when they were incorporated with the Oriental collection in the Royal Library. Renaudot wrote the following works:—1, A collection of controversial pieces on the celebrated work by Nicole, entitled 'Défense de la Perpetuité de la Foi contre les Monuments authentiques de la Religion des Grecs,' Paris, 1708, 8vo.; 2, 'Historia Patriarcharum Alexandrinorum Jacobitarum,' &c., Paris, 1713, 4to.; 3, 'Liturgiarum Orientalium Collectio,' Paris, 1716, 2 vols. 4to.; 4, 'Antient Account of India and China,' written by two Mohammedan travellers of the ninth century, translated from the Arabic, Paris, 1718, 8vo. This has subsequently been found to be only a translation of part of a geographical and historical work, entitled *Murúju-dh-dhahab wa mádanu-jauhar* (meadows of gold and mines of gems), by the celebrated Masudí, an Arabian writer of the tenth century. 5, 'Gennadii Patriarchæ Constantinopolitani Homiliæ de Eucharistia,' together with other Latin treatises on the same subject, Paris, 1703, 4to.

RENDSBURG is a fortified town of Denmark, in the duchy of Holstein, and the capital of a bailiwick of the same name, the area of which is 290 square miles, and includes five parishes. It is situated in 54° 18′ N. lat. and 9° 40′ E. long., partly on a heath, partly on an island at the mouth of the Eyder, at its junction with the Holstein canal. It consists of three parts, the Old Town built on the above-mentioned island, the New Town on the Holstein bank of the river, and the Crown-work, with the last sluice of the canal, and some warehouses, all on the Schleswig side. It has 4800 inhabitants without the military, who amount to 3500 men. There are two churches, an hospital, a house of correction, a gymnasium, a military academy, a board of trade, and a custom-house. It is the residence of the superintendent-general (a high dignity in the Lutheran church); and the military chest of the duchies of Schleswig, Holstein, and Lüneburg is in the town. The place has manufactures of stockings, pottery, tobacco, and vinegar.

RE'NE' OF ANJOU, born in 1409, was the son of Louis II., duke of Anjou and count of Provence. In 1434 he succeeded his brother Louis III., who died in Calabria while waiting for the succession of Queen Joanna II. of Naples, who had named him her heir. Before this time, Réné had married Isabella of Lorraine. After the death of Queen Joanna II., in 1435, Réné laid claim to the kingdom of Sicily and Naples, but he had a powerful rival in Alfonso of Aragon. [ALFONSO V; JOAN II.] Réné was then a prisoner of the duke of Burgundy, who opposed his succeeding to the inheritance of Lorraine, which he also claimed after the death of the duke, his father-in-law. He sent however his wife Isabella to Naples with her younger son Louis. She was received with acclamations by the old and numerous partisans of the house of Anjou. Alfonso of Aragon was then a prisoner in the hands of Filippo Maria Visconti, duke of Milan; but soon after having recovered his freedom, he repaired to South Italy to dispute the crown of Naples with his rival. In 1438 Réné came to Naples, and a desultory warfare was carried on for three years in the Abruzzo and other provinces of the kingdom. The death of the Condottiere Caldora, Réné's best officer, decided the struggle in favour of Alfonso, who laid siege to Naples, and took it in 1442. Réné escaped on board a Genoese vessel to Provence. He was the last of the dynasty of Anjou who sat on the throne of Naples. In 1445 Réné gave his daughter Margaret in marriage to Henry VI. of England, on which occasion he obtained the restoration of the territories of Anjou and Maine, which were in the possession of the English. Réné now resided sometimes at Angers and occasionally at Aix in Provence, occupying himself with the administration of his territories, and also with the arts of painting, poetry, and agriculture. He wrote several works both in prose and verse, among others one on tournaments, the MS. of which, enriched with drawings, is preserved in the National Library at Paris. In 1449-50 Réné attended King Charles VII. of France in his successful war against the English, after which he returned to his dominions to pursue his favourite occupations. His eldest son John attempted to take Naples from Ferdinand of Aragon, who had succeeded Alfonso, but his enterprise failed. In 14[illegible] Louis XI. of France seized Anjou under some pretence, and Réné retired to Aix in Provence, where he died in 14[illegible], regretted by his subjects, among whom he has retained the enviable appellation of 'le bon Roi Réné,' for he continued to style himself king of Sicily and Jerusalem. He introduced several useful trees and plants into Provence, among others the muscadel grape, and encouraged manufactures of woollens and glass. A 'Précis historique' of his life was published by Boisson de la Salle, Aix, 1820, and a marble statue was raised to his memory in one of the squares of Aix, in 1823. Réné's sons having died before him, he was the last representative of the house of Anjou, and after his death Provence was united to France. Bargemont, Vic[illegible] de Villeneuve, has published 'Histoire de Réné d'Anjou, Roi de Naples, Duc de Lorraine, et Comte de Provence,' Paris, 1825.

RENFREW. [RENFREWSHIRE.]

RENFREWSHIRE, a county in the west of Scotland, bounded on the north by the River Clyde, by which it is separated from Dumbartonshire, on the north-east and east by the county of Lanark, on the south and south-west by the county of Ayr, and on the west by the Frith of Clyde. It includes a small portion on the right or north bank of the Clyde, by which this portion is separated from the rest of the county. Its form is that of an irregular oblong, having its greatest length from the junction of the three shires of Ayr, Lanark, and Renfrew, on the south-east, to the banks of the Frith of Clyde, at the point or head land north of Innerkip, in the north-west, 32 miles; and its greatest breadth at right angles to the length, from the shore of Kilbirnie Loch to Erskine House on the Clyde, [illegible] miles. It is included between 55° 40′ and 55° 58′ N. lat. and between 4° 14′ and 4° 54′ W. long. (*Map of Scotland*, pub. by Soc. for the Diff. of Useful Knowledge.) Its area is given by Playfair (*Description of Scotland*) at 225 square miles, or 144,000 English acres; and by MacCulloch (*Statist. Account of British Empire*) at 227 square miles ([illegible] of them water), or 145,280 acres, of which 1280 are water. In Chambers's 'Gazetteer of Scotland' the area is given at [illegible] square miles, or 154,240 acres. The population in 1801 was 78,056; in 1811, 92,596; in 1821, 112,175; and in 18[illegible], 133,443; showing an increase, steadily maintained, in [illegible] years, of 55,387, or above 70 per cent.; and giving (on Playfair's estimation of the area) 593 inhabitants to a square mile, a density of population unequalled by any county in Scotland except Edinburghshire, and in England by any except the metropolitan counties of Middlesex and Surrey, and the great manufacturing county of Lancashire. The greater part of the population is gathered round Paisley, Greenock, and Port Glasgow. Renfrew, the capital, is on the Clyde, in 55° 53′ N. lat. and 4° 22′ W. long.

Surface, Geology, Hydrography, and Communications.—The western part of the county, and the southern border which joins Ayrshire, are hilly; the eastern part, especially along the Clyde, is comparatively flat. The hills on the border of Ayrshire are the loftiest. Dunrod hill, Gar[illegible] hill, and Creuch hill are near the western extremity of the border; Queenside, Mistylaw (1240 feet high), the hill of

Stalk (higher than Mistylaw), the Fereneze hills, the Lochliboside hills and Neilston Pad (the last two rising from 800 to 900 feet), are near the middle of it; and Balagech (1000 feet high) is near the western extremity. Mistylaw or Staunly Bran 1640 feet high is the culminating of the Green Nose hills, which extend toward the centre of the county. The principal eminence of the Lochliboside hills is called Corkindale Law.

The south-eastern part of the county is included in the great coal district of the west of Scotland. The chief coal-works are at Quarrelton near Johnstone; and at Hurlet and Househill near Paisley; the mines here are very productive. In the coal-works at Hurlet, a bed of slate over the coal has, by combination with sulphuric acid, been converted into alum-slate; and a considerable alum-work, perhaps the largest in Great Britain, has for some time been carried on. Limestone, sandstone, ironstone, granite, and secondary trap-rocks are found in considerable abundance. The hills about Mistylaw and Stalk are mostly porphyry, capped with greenstone, which intersects the porphyry in innumerable dykes. Alluvial and diluvial beds are observed along the banks of the Clyde. Good freestone for building is quarried; limestone is also wrought for burning; and the coal and ironstone mines give employment to many persons.

The whole county is included in the basin of the Clyde, the estuary of which washes a large portion of the border; but the tributaries which drain it are all small, and, with one exception, useless for the purpose of navigation. A stream which bears, in different parts of its course, the names of Hollow Burn, Sicaw Burn, and Kipp Water, drains the western part, and joins the estuary of the Clyde at Innerkip on the west side of the county. In one part of its course it expands into two ponds or lochs, one of them above a mile in length, used as reservoirs for a cut made to supply Greenock with a stream of water for turning the mills on the heights above that town. The central and eastern parts of the county are drained by three streams: the Gryfe, which flows from the westward; the Black Cart, which rises in Ayrshire, expands, at or near its source, into Kilbirnie Loch and Castle Semple Loch, and unites with the Gryfe about 3 miles north-west of Paisley; and the White Cart, or, by way of eminence, 'the Cart,' which rises on or near the eastern boundary, and drains the eastern side of the county, then, passing through Paisley, joins the united stream of the Black Cart and the Gryfe, just above its entrance into the Clyde near Renfrew. The White Cart is made navigable partly by an artificial cut to the Clyde. Although the other streams are not large enough for navigation, they supply moving-power to the mills or other machinery. Fish are not abundant in the White Cart; but in Castle Semple Loch pike and eels are found in great number; this loch is also much frequented by waterfowl. Beside the lochs already noticed, there are some others, but all small. The banks of Castle Semple Loch and Loch Libo are well wooded and picturesque.

The only canal is the Ardrossan, which was designed to open a communication between Glasgow and Ardrossan on the Ayrshire coast. It has never been carried farther than from Glasgow to Johnstone in Renfrewshire, about 11 miles from Glasgow; it passes Paisley. The breadth of the canal at the surface is 29 feet; the depth 4½ feet; it passes through two tunnels, both at Paisley, and is carried over the White Cart by an aqueduct bridge. The traffic on the canal, which is very great, is carried on by luggage boats for goods and 'gig boats' for passengers. The traffic may be estimated by the following statement:—

	Passengers.	Tons of Goods.
1831	79,455	48,191
1832	142,516	51,193
1833	240,062	53,194
1834	307,275	57,833
1835	373,290	60,510
1836	423,186	67,085

There is a railway from Paisley to the Clyde at Renfrew three miles and a quarter long. A railway from Glasgow to Paisley and Greenock, almost the whole of which is in this county, and one from Glasgow to Paisley, Johnstone, Irvine, and Ayr, partly in this county, are nearly if not quite completed. They have a joint line to Paisley. The main line of the Glasgow and Ayr railway is open. Some interesting details of these railways are given in the 'Companion to the Almanac' for 1841. Coach and other roads from Glasgow to Port Glasgow and Greenock run, one near the banks of the Clyde through Renfrew, another more inland through Paisley. Roads from Glasgow by Paisley run through the valley of Castle Semple Loch, one to Kilbirnie, Ardrossan, and Saltcoats, the other to Beith, Irvine, and Ayr. A more direct road from Glasgow to Irvine, and a road from Glasgow to Kilmarnock and Ayr, cross the eastern side of the county. Besides these principal lines of communication, there are less frequented roads crossing the county in every direction.

Climate, Soil, Agriculture.—The hilly parts of the county on the west and south are chiefly devoted to pasture; scarcely more than half the whole surface of the county is under cultivation. The cultivated part is on the north and north-east, and in the centre; where the soil is most fertile. The uncultivated districts comprehend bleak moors or hills, with comparatively extensive bogs in some parts. Owing to the demand for meat, vegetables, milk, butter, &c., by the large and crowded population of Greenock, Port Glasgow, and Paisley, a large part of the cultivated land is meadow-land or garden-ground. Potatoes usually form part of every rotation of crops: a common rotation is as follows:—1, oats from grass; 2, potatoes or barley; 3, oats sown with red clover or rye-grass seeds; 4, hay; and 5 and 6, pasture: another common rotation consists of—1 and 2, oats; 3, barley; 4 and 5, hay; and 6 to 10, pasture. Dry stone dykes are in use in some parts of the county for fences; but where the soil is better and more under cultivation, hedges are used. Tile-draining and the use of bone-manure are rapidly extending. Dairy farming is very extensively practised. There are some large estates, and more than half the valued rent is of entailed or corporate property, but property in the rest of the county is a good deal subdivided. Farms are middle-sized, and farm-houses and buildings of middling character.

Divisions, Towns, &c.—There are fifteen parishes in the county, reckoning Paisley and Greenock each as one; and portions of four others, Beith, Cathcart, Dunlop, and Govan, which are partly in Lanarkshire or Ayrshire. There are four burghs: Renfrew, population in 1831, 2833; Greenock, population 27,571 [GREENOCK]; Paisley, population 57,466 [PAISLEY]; and Port Glasgow, population 5192 [GLASGOW]. The principal villages are Johnstone, Gourock, Eaglesham, Kilbarchan, Lochwinnoch, Pollockshaws, and Neilston.

Renfrew, the shire town, is about 6 miles north-west of Glasgow on the road to Greenock. The Stuart family had their earliest known patrimonial inheritance in this parish. Renfrew was a royal burgh, and with its territory and other possessions was granted by David I. (who reigned A.D. 1124-1153) to Walter, son of Alan, whom he at the same time created steward of his household, or, as it was afterwards called, steward of Scotland, a dignity which became hereditary in the family, whence the name of Stewart or Stuart. By virtue of this grant Renfrew ceased to be a royal burgh, and became a burgh of barony; but when the Stuarts came to the throne, it regained its rank as a royal burgh by grant from Robert III., A.D. 1396. The parish of Renfrew comprehends 3875 acres, mostly under cultivation: the population in 1831 was 2833; of whom 2002 were in the burgh. About one-sixth of the population was agricultural. The number of inhabited houses in 1831 was 268 for the town, or 365 for the whole parish. The town is on the east side of the parish, near the Clyde, and consists of one main street along the Glasgow and Greenock road, and some smaller streets. From the burgh to the Clyde is a short canal, about half a mile long, partly formed in the Pudzeoch Burn, once an arm of the Clyde; along the canal is a commodious quay, and across it is a timber drawbridge. Two bridges, one below the junction of the Black Cart and the Gryfe, the other (Inchinnan bridge) below the junction of the White Cart with the united stream, are on the border of the parish remote from the town. The church is a cruciform structure, insufficient for the accommodation of the parishioners. There are a town-house, jail, and school-house. The number of prisoners in the gaol does not amount to half a dozen in the year, mostly debtors; and the period of confinement is commonly short. The manufactures are various: muslin-weaving is by far the most important, and employs about 500 or 600 persons, half weavers, the rest (either women or children) in winding or drawing. Many females are employed in clipping, tambouring, and flowering. There is a considerable bleach-field, employing about

100 persons, chiefly women and children. Starch and draining-tiles are made, malt spirit distilled, and coal-works wrought. The coal-works employ 30 to 40 men or boys in the pits, and many others above ground. A few small vessels carrying coal, manure, &c. on the Clyde, belong to the burgh; but a considerable number of vessels, chiefly laden with grain from Ireland or with dye-stuffs for Paisley, discharge their cargoes here. Potatoes and fish are brought here from the Highlands. There is no regular market: there are three fairs in the year, chiefly for cattle.

The corporation consists of a provost, two bailies, and sixteen councillors; the burgh revenues are estimated at about 1400*l.* or 1500*l.* per annum. A weekly court for the administration of justice is held by the magistrates, and the quarter-sessions for the county are held here, but the sheriff-court is held at Paisley. Renfrew was formerly united with Rutherglen, Glasgow, and Dumbarton in returning a member to Parliament; by the Reform Act it has been connected with Kilmarnock, Rutherglen, Dumbarton, and Port Glasgow. The number of voters in the borough is about 80. The parliamentary boundary is more restricted than the antient burgh limits. The election for the county is held here.

There were in 1836 an endowed burgh grammar-school, and five other weekly schools, attended by about 327 day and 90 evening scholars. About 390 children attended Sabbath-schools, and a youth's class of about 60 was taught by the minister. There were a parish library, a subscription library, and a news-room in the burgh; and an association was being formed for the cultivation of natural history and the useful arts. Most of the Sabbath-schools had juvenile libraries. There were several benefit societies, a Bible society, and one or two other charitable institutions. (*New Statistical Account of Scotland.*)

Johnstone is in the parish of Paisley, about three miles west of Paisley town, and is partly noticed elsewhere. [PAISLEY.] The village has risen by the introduction of manufactures: it had in 1831 a population of 5617. In the centre is a large square entirely surrounded with houses, and a new square and market-place to the south of this are probably by this time completed. There are several streets lined with substantial houses of two stories, roofed with slate. There are a chapel-of-ease, several dissenting meeting-houses, a subscription library, two news-rooms, and a mechanics' institution and library. There are eleven cotton-mills in the town, and several more in the neighbourhood, beside brass-foundries, iron-foundries, machine-manufactories, and gas-works.

Gourock is a small burgh of barony on the Frith of Clyde, about three miles below Greenock, in the parish of Innerkip. Its regular inhabitants are chiefly fishermen; and it is said that this was the first place in Great Britain in which red herrings were cured. There is a ropewalk. Gourock is resorted to in the season as a bathing-place. It has a neat chapel-of-ease. The population of Innerkip parish in 1831 was 2088, about one-fourth agricultural. Innerskip is also resorted to by bathers.

Eaglesham is near the south-eastern extremity of the county, nine miles south of Glasgow. It is a neat village, rebuilt in 1769 by the Earl of Eglintoun, and consists of two rows of houses, 200 yards apart; the intermediate space, through which a rivulet flows, is chiefly used as a bleach-green. There is a cotton-mill in the village, which employs many hands: there are others in the parish. Lawn is woven here. There is a market, and there are four yearly fairs. The church of Eaglesham was built A.D. 1790, by the Earl of Eglintoun; and there is a Secession meeting-house. The population of the parish in 1831 was 2372.

Kilbarchan is a mile and a half west of Johnstone. The houses are mostly of freestone quarried in the neighbourhood. The inhabitants are chiefly engaged in cotton and silk weaving; and the young women are expert in tambouring, embroidering, and flowering muslin. Kilbarchan has a parish church, several meeting-houses, two public libraries, and an agricultural society. There are two other thriving villages in the parish, called the Brig o' Weir (or Bridge of Weir) and Linwood. The population of Kilbarchan parish in 1831 was 4806.

Lochwinnoch is near the western bank of Castle Semple Loch. It is a large village; the houses are generally of two stories, and slated; cotton-spinning is the chief branch of manufacture; but muslin-weaving, wool carding and spinning, and the manufacture of Angola shawls, Canton crapes, and other fabrics are carried on. There are a large parish church and a Secession meeting-house. There are three libraries, two parochial and one other, besides a library for the children attending the Sunday-schools, and several book-clubs. There are three yearly fairs at Lochwinnoch. Population of the parish, in 1831, 4515.

Pollockshaws is in Eastwood parish, about three miles from Glasgow. It is a tolerably large place, consisting of several streets, in a pleasant situation. It has a town-house with a tower and clock, a church rebuilt in 1781, and two places of worship for Seceders, and a small prison or lock-up house. The place depends almost entirely on the cotton manufacture; spinning, weaving, bleaching, and printing are actively carried on. This place was made a burgh of barony by a grant from the crown. There were five schools in the parish in 1836, attended by about 600 day or evening scholars. There are several benefit societies. Coal and stone are procured in various parts of the parish. The population of Pollockshaws in 1831 was 4627; of the whole of Eastwood parish, 6854.

Neilston is nine miles from Glasgow, on the road to Irvine. The population of the village is nearly 2000; that of the whole parish, in which there are some other large villages, was, in 1831, 8046. Cotton-mills, print-fields, and bleach-fields are numerous; freestone and whinstone are quarried, and coal is dug in the parish. The church of Neilston contains some remains of antient Gothic architecture. There is a Secession meeting-house. Five fairs are held in the parish yearly.

The cotton-manufacture is also carried on to some extent in the parishes of Houston, Killellan, and Mearns.

Ecclesiastical and Legal Arrangements.—Of the nineteen parishes which are wholly or partly in Renfrewshire, two, viz. Beith and Dunlop, are in the presbytery of Irvine; three others, Cathcart, Govan, and Eaglesham, in the presbytery of Glasgow; and the rest in the presbytery of Paisley. These presbyteries are all under the synod of Glasgow and Ayr.

The quarter-sessions for the county are held at Renfrew, also the meetings of the commissioners of supply, and the court of election for the member of parliament for the county; but in case of an adjournment of any of these courts, they are generally transferred to Paisley. The sheriff-court for the county was held at Paisley before the appointment of a second sheriff-substitute, since which time two sheriffs' courts have been held for the two divisions of the county, one at Paisley, the other at Greenock. There are a gaol and a house of correction or bridewell for the county and the burgh of Paisley, in one building, at Paisley. It is a substantial edifice, containing in all 77 cells or rooms, viz. 43 in the bridewell, and 34 in the gaol; the discipline of the bridewell was reported by the Inspectors of Prisons, in their Second Report (in Dec., 1836), to be very good, that of the gaol to be very bad; but a later Report, the fourth (Nov., 1839), speaks of considerable improvement. There are small burgh prisons for debtors and criminals at Renfrew, Greenock, and Port Glasgow, and a lock-up-house at Pollockshaws. Several new prisons are required. 'There appears to be much crime in this county: the offences consisting chiefly of thefts and assaults. Housebreaking also is common, though seldom or never accompanied by personal violence. It is stated that there has been a great decrease of murders and highway robberies within the last thirty years; but it is said that the number of petty thefts has increased, and that beyond the increase of population. The places most distinguished for crime in Renfrewshire are reported to be Paisley, Greenock, Neilston, and Pollockshaws. Most of the offenders are said to be from ten to twenty years old. Drunkenness is looked upon as being the chief cause of crime in the county. The procurator fiscal at Greenock having taken twenty cases indiscriminately, and examined into their origin, found that nineteen of them arose from whiskey. Many of the offenders have no knowledge of a trade, and many of their parents are known to be of bad character. The offenders are generally found to be ill educated—more so than others in the same rank of life. Indeed in this respect they appear to be inferior to their predecessors thirty years ago; for the sheriff-substitute of Paisley states that at that period more came before him who could write than now. This want of education is particularly noticed among the Irish, who constitute a considerable portion of the offenders, and whose number in the county has greatly increased of late years, a fact which probably explains the apparent falling off in education among the poorest class.' (*Third Report of the Inspectors of Prisons*, Dec., 1837.) 'There is great want of a good police in the county.' (*Ibid.*)

The county returns one member, who is elected at Renfrew. Paisley and Greenock return one member each; and Renfrew and Port Glasgow unite with Dumbarton, Rutherglen, and Kilmarnock, to return another.

The county included, in 1833-34, 19 parochial schools with 22 instructors, attended by a number of children varying from 656 (viz. 419 boys and 237 girls) to 920 (viz. 577 boys and 343 girls); and 120 schools not parochial, with 193 instructors and a number of children varying from 5127 (viz. 2963 boys and 2164 girls) to 9747 (viz. 5276 boys and 4671 girls): no other children than those receiving daily instruction are included in the foregoing summary.

History, Antiquities, &c.—In the earliest historical period this county seems to have formed part of the territory of the Damnii, who occupied portions of the adjacent counties of Ayr, Lanark, Stirling, and Dumbarton. Under the Romans it was comprehended in the province of Valentia; and a Roman town or post (Vanduaria) is fixed by some at Renfrew, but more commonly at or near Paisley. It appears to have been subsequently included in the British kingdom of Strathclyde, and afterwards in the kingdom of Scotland. A large part of it came into the hands of the Stewards of Scotland, progenitors of the Stuart family, by grant from the Scottish kings or by other means, especially Strath-Gryfe, or the valley of the Gryfe. A body of the Renfrew men, called, from the Levern or Levern, a feeder of the White Cart, *Lawernani*, were present at the battle of the Standard, in the reign of David I., A.D. 1138. In a later period Renfrewshire made part of the principality formed out of the Stuart domains as an appanage for the eldest sons of the kings of Scotland; in consequence of which arrangement, the district, which was previously under the sheriff of Lanark, was formed into a separate county. Renfrew still gives the title of baron to the eldest son of the reigning king.

Of these ancient times Renfrewshire contains a few memorials. Paisley abbey is noticed elsewhere. [PAISLEY.] There are some antient camps. Some antiquities, supposed to be druidical, exist in the parishes of Kilbarchan and Lochwinnoch; but they are of little moment. Barr Castle and Elliston Castle, both in Lochwinnoch parish, Peel Castle on Castle Semple Loch, and Newark Castle near Port Glasgow, belong to the middle ages. Elliston is said to have belonged to the progenitors of Wallace, and popular tradition connects some of the exploits of that hero with localities in Renfrewshire.

The battle of Langside, in which the Regent Murray [MURRAY, JAMES STUART, EARL OF] defeated the last attempt of Mary Queen of Scots to regain her throne, was fought just within the eastern border of the county. The battle of Muirdykes, in which those who supported the attempt of the Duke of Argyle in 1785 (contemporaneous with that of the Duke of Monmouth in the west of England) were defeated, was fought in Lochwinnoch parish in this county.

RENI, GUIDO. [GUIDO RENI.]

RENNELL, JAMES, born near Chudleigh in Devonshire, in 1742, entered the navy at an early age as a midshipman. His father was a captain in the artillery. Young Rennell went with Admiral Parker to India, and rendered some effectual service at the siege of Pondicherry. At the age of twenty-four he quitted the navy, and entered the corps of engineers in the service of the East India Company. He distinguished himself in the campaigns of Lord Clive, received some severe wounds, and was promoted to a majority. It was during this period that he produced his first work, 'A Chart of the Bank and Currents of Cape Agulhas,' the most southern point of Africa. While he was stationed in Southern India, he surveyed Adam's Bridge and the Paumbeen Passage between the island of Ramisseram and the continent, and he expressed his conviction of the practicability of widening the passage for ships. This suggestion has been lately acted upon, after a lapse of seventy years. While he held the appointment of surveyor-general of Bengal, he published his 'Bengal Atlas,' with an account of the Ganges and the Brahmapootra, in which he conjectured that the Sanpoo of Tibet was the main feeder of the latter river. [BRAHMAPOOTRA.] On his return to England, in 1782, Major Rennell published a map of Hindustan, accompanied by a Memoir, 4to., 1788. He was also elected member of the Royal Society, and became intimate with Dr. Vincent, Sir Wm. Jones, Dr. Horsley, bishop of St. Asaph, and other learned men of his time. In 1793 he published 'Marches of the British Army in the Peninsula of India during the Campaigns of 1791.' He also published 'Memoir of a Map of the Peninsula of India, exhibiting its Natural and Political Divisions, the latter conformably to the Treaty of Seringapatam, of March, 1792;' and also 'Elucidations of African Geography, from the Communications of Major Houghton and Mr. Magra, in 1791, with a Map.' In 1794, Major Rennell published a political pamphlet, entitled 'War with France the only Security of Great Britain at the present momentous crisis, by an Old Englishman.' The French Convention had already placed themselves out of the pale of international law by their resolutions of the 19th of November, 1792, in which they offered their aid to any people in any country of Europe who wished to overthrow the existing government. In 1798 he assisted Mungo Park in the arrangement of his African travels, and illustrated his work by a map and a memoir in the appendix. His next work, and that by which he is most generally known, was 'The Geographical System of Herodotus examined and explained,' 4to., 1800. He also wrote:—1, 'Observations on the Topography of the Plain of Troy;' 2, 'A Treatise on the Comparative Geography of Western Asia,' with an Atlas, a work of great labour and research; 3, 'Illustrations, chiefly Geographical, of the History of the Expedition of the younger Cyrus from Sardis to Babylon, and the Retreat of the Ten Thousand;' 4, 'An Investigation of the Currents of the Atlantic Ocean, and of those which prevail between the Indian Ocean and the Atlantic.' For this important work he examined and collated the log-books of all the ships of war and Indiamen which had traversed those seas during the last thirty or forty years, re-computing their observations and reducing them to one general system. The results of all this prodigious labour were ready for the press at the time of his death, and were shortly afterwards published by his daughter, Lady Rodd, in several large charts, showing by an infinite number of arrows the direction and force of the currents throughout the Atlantic ocean, and accompanied by a thin volume which ought to be studied by every seafaring person. Major Rennell also wrote some papers in the Transactions of the Royal and Antiquarian Societies, such as a Disquisition on the Melita Island of St. Paul's voyage; the place of Julius Cæsar's landing in Britain, in which he proves that the principal mouth of the Thames was then to the southward of the Isle of Thanet, &c. Major Rennell died on the 29th of March, 1830; and on the 6th of the following April his remains were interred in Westminster Abbey, where a tablet with an appropriate inscription is placed over his tomb. Biographical notices of him were inserted in the periodicals of the time, in which both his public and his private character were spoken of in those terms of praise which he justly deserved.

The merits of Major Rennell as a laborious investigator and an acute critic are universally acknowledged. Love of truth, patient and persevering research, and sound judgment are eminently displayed in all that he did. It is a matter of surprise, with the limited means at his command, that he accomplished so much in the department of comparative geography; and though we are now enabled, by new discoveries, to rectify many of his conclusions, the results to which he did attain will always remain as evidence of his unrivalled sagacity. His 'Geographical System of Herodotus' is a monument worthy of the writer whom he illustrated. Though unacquainted with the Greek language, and obliged to trust to the very inaccurate version of Beloe, he succeeded in producing a commentary on a classical author which is not surpassed by the labour of any scholar. The blundering of Beloe, and his occasional complete perversion of the original, did not mislead the geographer, who could detect the author's meaning, even under the disguise of the translation. (*Journal of Education*, vol. i., p. 350, &c.) As a geographer, Major Rennell was one of the last Englishmen who has earned any permanent reputation; and in illustrating Herodotus and the Retreat of the Ten Thousand, he occupies a place by the side of D'Anville.

RENNES, a town in France, capital of the department of Ille et Vilaine, 186 miles in a direct line west by south of Paris, or 213 miles by the road through Versailles, Dreux, Alençon, Mayenne, and Laval; in 48° 6′ N. lat. and 1° 42′ W. long.

This town, at the time of the Roman conquest, bore the name of Condate. It is mentioned by Ptolemy as the chief town of the Redones, a Celtic nation, and is also mentioned in the Itinerary of Antoninus and the Table of Peutinger. At a later period it took the name of the people to whom it belonged, Redones, from which is derived the modern name of Rennes. In the ninth century, when the kingdom of Bretagne was restored by Nomenoé [BRETAGNE], Rennes was taken by that prince, and either then or some time afterwards became capital of Bretagne. In the anarchy which prevailed in Bretagne towards the close of the ninth century, Rennes was the capital of a county till A.D. 992, when Count Geoffroi of Rennes assumed the title of duke of Bretagne; after which event it became again the capital of all Bretagne. In the struggle between De Montfort and De Blois for the ducal coronet, Rennes, then held by the partisans of De Blois, was besieged for six months by John of Gaunt, duke of Lancaster, but he was obliged to raise the siege. Before the Revolution the states of Bretagne met at Rennes, and it was the seat of a parliament instituted A.D. 1555, by Henri II.

In 1720 the town of Rennes was laid waste by a fire, which lasted from the 22nd to the 29th of December, and consumed twenty-seven streets, five squares, and eight hundred and fifty houses in the very heart of the place. The new part, rebuilt after this catastrophe, forms one-third of the town, or, including the faubourgs or suburbs, one-fifth. It is distinguished by wide and straight streets intersecting at right angles. The town stands in a plain watered by the Vilaine and its tributary the Ille, which unite a little below the town. It is surrounded by an antient wall and towers, and, though of little strength, still ranks as a fortress. The Vilaine divides Rennes into two parts, the upper town on the north bank, and the lower town on the opposite bank, which are united by three bridges. The lower town, which is the smaller, is built on a low flat site, frequently inundated, and has narrow and crooked streets, with houses mostly built of wood, curiously carved and highly picturesque. The faubourgs or suburbs, which are large, resemble the lower town in character. The upper town is between the Vilaine and the Ille, on a site little more raised than the lower town; it comprehends the new quarter, and has well-paved streets, large squares or 'places,' and generally lofty well-built houses. Vaysse de Villiers however speaks of the place as dull and gloomy, characteristics which may be partly ascribed to the sombre tint of the granite or sandstone of which the houses are built, and partly to the dulness of the climate, the flatness of the surrounding country, and the sluggish and muddy current of the Vilaine. The principal 'places' or squares are La Place du Palais, so called from the Palais de Justice, which forms the north side of it, and La Place d'Armes, or Parade, larger than La Place du Palais, but not so handsome. There are several public walks: that of La Motte, which separates the Faubourg de Paris from the town; the promenade on the quay of the Vilaine, nearly a mile in length; the Champ de Mars; and Le Mail · the last just at the junction of the Ille and the Vilaine.

The cathedral is a heavy and ugly Gothic structure; a new cathedral, dedicated to St. Pierre (Peter), was commenced after the great fire of 1720, but, according to our latest authorities, is not yet finished. The two towers of the principal front form a conspicuous object in a distant view of the town, but on a closer view by no means answer the expectations excited. Of the other churches, that of St. Sauveur is the handsomest. Le Palais de Justice, or court-house, is a building having a front of the Tuscan order, heavy and ill-proportioned; the other three sides are adorned with Corinthian pilasters. It is appropriated to the administration of justice and to the study of the law, and is decorated with paintings and arabesque ornaments. The Hôtel de Ville (town-hall) is a building of less architectural pretension but more pleasing appearance than the Palais de Justice. Over the central part rises a clock-tower: it contains the rooms for the tribunal of commerce and the public library. Among the other public buildings are the office of the prefect, the episcopal palace, the ex-abbey of St. Georges, now occupied as a barrack, the Hôtel Kergus, antiently a school or college, now a barrack, and the Hôtel Blossac.

The population of the commune of Rennes, in 1826, was 29,377; and in 1831, 29,680, of whom 27,340 were in the town and the immediate suburbs; and, in 1836, 35,552. The manufactures of the place are not extensive, but comprehend a variety of articles—linen and cotton yarn, sail-cloth and stout linens, common flannels, hosiery, lace, cordage, nets, hats, gloves, starch, glue, earthenware, porcelain, candles, and liqueurs. There are tan-yards, curriers' shops, and wax-bleaching houses. A pretty considerable trade is carried on in these articles, and in the honey, wax, poultry, and butter of the surrounding district. The Vilaine is rendered navigable by locks up to the town, and communicates with the little port of Rédon. The canal of the Ille and the Rance communicates with the port of St. Malo, and roads converging at the town communicate with St. Malo, St. Brieuc, Brest, Lorient, Vannes, Rédon, Nantes, and other places on or near the coast of Bretagne. There is a fair on the 1st of each month.

Rennes is the seat of a bishopric, comprehending the department in its diocese; the bishop is a suffragan of the archbishop of Tours. It has a Cour Royale, or court of justice, and an Académie Universitaire, the jurisdiction of which extends over the five departments of Ille et Vilaine, Côtes du Nord, Finistère, Morbihan, and Loire Inférieure; and it is the head quarters of the thirteenth military division, which includes the same departments except Loire Inférieure. There are a number of fiscal or administrative government offices; a prison or house of correction for the department, subject to the jurisdiction of the Cour Royale; an arsenal, an artillery forge, royal schools for artillery and riding, and several other military establishments. The educational establishments are important. There are a law school, a secondary school of medicine, a high school or college, two seminaries for the priesthood, some schools of mutual instruction, a society of arts and sciences, and a school of painting. The public library was formed a century ago by a body of advocates, and augmented by the spoils of the monasteries plundered at the Revolution: it now contains 30,000 well-chosen volumes, including some of the rarest and earliest editions of the antient classics, and some valuable MSS. There is a small well-chosen cabinet of paintings; and there are cabinets of physics, natural history, antiquities, and medals; a botanic garden, and a theatre. There are several churches, four hospitals, a maternity society, and several public baths.

Among the eminent natives of Rennes are the Benedictine Lobineau, who died A.D. 1721, author of a well-known history of Bretagne, and, in conjunction with Felibien, of the history of Paris; Tournemine, the Jesuit, who died A.D. 17[illegible], author of a history of the Jews; L'Abbé de la Bletterie, who died A.D. 1772, author of a history of the Roman emperor Julian, and translator of Tacitus; several eminent lawyers, the engineer Vauban, and the count Lanjuinais.

The arrondissement of Rennes has an area of 525 square miles, and comprehends 78 communes. The population, in 1831, was 126,375; in 1836, 130,838. It is divided into cantons or districts, each under a justice of the peace.

RENNIE, JOHN, was a native of Scotland, and born on the 7th of June, 1761, at Phantassie in Haddingtonshire, where his father was a respectable farmer. He acquired the rudiments of education at the school of the place, and afterwards received instruction in the elementary part of mathematics at Dunbar, where, on the promotion of the master, he for a short time conducted the school.

It does not appear that Rennie pursued his studies far in pure mathematics, but his taste leading him to contemplate the nature and properties of machines, he probably applied himself chiefly to those parts of science which relate to elementary mechanics, and it is certain that he made himself a proficient in the useful art of drawing machinery and the different objects which belong to practical architecture. He also took advantage of such opportunities as his avocations afforded to attend the courses of lectures on mechanical philosophy and chemistry which were then given at Edinburgh by Drs. Robison and Black. Prepared thus with what books and professors could teach, he entered the world; and it may be said that, during all the course of a useful life, he was adding to his stock of knowledge, seeking the means of improving his practice by observing the operations and effects of his own works, as well as those which were executed by other men.

Mr. Rennie was employed for a time as a workman by Mr. Andrew Meikle, a mechanist of his native parish, under whose superintendence he assisted in the erection of some mills in the neighbourhood; and he is said to have built, on his own account, one near Dundee. It is probable that soon after this work was finished, or about 1780, Mr. Rennie, feeling himself qualified to practise the profession of civil engineering on a greater scale than his own country at that time afforded, set out for London. On his way he visited the docks at Liverpool, and spent some months at Soho near Birmingham, in examining the works of Messrs. Boulton and Watt, to whom he had brought letters of introduction from the professors at Edinburgh.

Soon after he was established in the metropolis, Mr. Rennie was employed by those gentlemen in the construction of two steam-engines, and the machinery connected with them, at the Albion Flour-Mills near Blackfriars Bridge. These steam-engines were of the kind called double, for which Mr. Watt had taken out a patent in 1782; each of them was of 50 horse power, and the two could turn twenty mill-stones. All the wheel-work was made of cast-iron, instead of wood, which had before been used in such machinery; and the talents of Mr. Rennie were particularly manifested in the methods which he adopted to render the movements steady. The works were finished in 1789; but they continued in operation only during two years, the whole of that great establishment having been unfortunately destroyed by fire in 1791.

Mr. Rennie continued to the last to be employed in the construction of steam-engines, or of the different kinds of machinery to which, as a first mover, steam is applied; and at the same time he was almost constantly engaged in designing or superintending those public works which have given him so just a claim to celebrity. Between 1799 and 1803 he constructed the stone bridge at Kelso, below the junction of the Tweed and Teviot. This work, as elegant in its design as valuable for its utility, consists of five elliptical arches carrying a level roadway, and over each pier are two small columns, which support the entablature. Mr. Rennie also built stone bridges at Musselburgh and other places in Scotland; but his master-piece of this kind is the Waterloo Bridge over the Thames. This bridge, so much distinguished by its grandeur and simplicity, was begun in 1811, and finished in six years. It consists of nine equal elliptical arches, 120 feet in span, and the faces of the piers are ornamented with coupled Doric columns. Besides the elegantly designed iron bridge over the Witham in Lincolnshire, he also built that which is called the Trafalgar or Southwark Bridge, over the Thames. The latter consists of three cast-iron arches resting on stone piers [BRIDGE], and the span of the centre arch is 240 feet.

Mr. Rennie superintended the formation of the Grand Western Canal, which extends from the mouth of the Ex to Taunton; and, in conjunction with Mr. Murray, that of the Polbrook Canal between Wade-bridge and Bodmin, in Cornwall. He also superintended the execution of the Aberdeen canal uniting the Don and the Dee, and of that between Arundel and Portsmouth. But his chief work in connection with inland navigation is the Kennet and Avon canal, which extends from Bath to Newbury, and which required all the skill of the engineer to conduct it through the rugged country between those places. He also gave a plan for draining the fens at Witham in Lincolnshire, which was executed in 1812.

The London Docks and the East and the West India Docks at Blackwall are among the great works which were executed from the plans and under the direction of Mr. Rennie; and at the last-mentioned Docks he constructed the sheds which cover timber and other merchandise; the roofs of these are formed of iron frames covered with slate and supported on iron pillars. He formed the new docks at Hull (where also he constructed the first dredging-machine which was used in this country), the Prince's Dock at Liverpool, and those at Dundee, Greenock, and Leith, of which the last is remarkable for the particularly strong construction of its sea-wall. [DOCK.] To these must be joined the famous pier or breakwater protecting Plymouth Sound from the waves which during high winds used to roll in with tremendous force. [PLYMOUTH.] Mr. Rennie also gave plans for improving the harbours of Berwick, Newhaven, and other places, and the dockyards of Portsmouth, Plymouth, Pembroke, and Chatham: he also built the pier at Holyhead.

Before his death he had given plans for improving the docks at Sheerness, which have since been executed by his first and second sons Messrs. George and John (now Sir John) Rennie: the gates are formed of cast-iron ribs, covered on the side next to the stream with cast-iron plates, and on the other side with planks of wood. It should be observed also that Mr. Rennie, sen. gave the designs for the present London Bridge; and that the charge of its construction was confided to Sir John Rennie, who, in 1831, finished that magnificent structure. [BRIDGE.] The span of its centre arch is 150 feet. The same gentleman executed also the light and elegant stone bridge which has replaced the old bridge of timber at Staines.

Mr. Rennie married in 1789, and had six children; four sons and two daughters. He survived his wife, and, till within a few years of his death, he enjoyed excellent health. He died of an inflammation of the liver, October 16, 1821, and was buried in St. Paul's Cathedral.

The sums expended in the construction of Mr. Rennie's bridges have appeared so great as to give rise to an opinion that the measures adopted for the stability of those structures exceeded those which a due regard to economy should warrant. Of this however it is scarcely possible to form a right judgment. It is true that the Waterloo Bridge cost more than a million sterling, but several circumstances contributed to make the expense of that bridge greatly exceed that of the bridges before built over the Thames; it is, in the first place, longer; the material is granite, and the piers were built in coffer-dams. Now, granite is more costly than any other species of building stone, both at the quarry and in the charges for working it into form; and a coffer-dam, with the engines necessary to keep out the water, is much more so than a caisson. But in a great public work durability is a primary consideration; and this is ensured by the employment of the best materials and by taking the most effectual means of securing the foundations. The expensive repairs which the bridges at Westminster and Blackfriars have required, and will continue to require, will probably, in the end, afford a full justification of the measures which have been followed in the construction of the Waterloo and the new London bridges. In the execution of machinery, Mr. Rennie may be said to have been the first who made that skilful distribution of the pressures, and gave those just proportions to the several parts, which have rendered the work of Englishmen superior to that of any other people.

We may here observe that the refined theories of the mathematician are too general to admit of being brought down to all the circumstances which depend on the constitution of material substances; and, from the minute division of labour among us, the artizan passing his life in the execution of one particular kind of work is seldom capable of making alterations by which a complex system of machinery might, as a whole, be improved. Therefore neither the profound philosopher nor the industrious operative can, alone, be expected to constitute a complete engineer; and if this character is to be attained, it will probably be found in a man in whom, as in the subject of this article, are united the thinking mind, and, to a certain degree, the labouring hand, and whose duties leave him sufficient leisure to investigate the mutual actions of bodies on one another by appropriate experiments.

RENT, in Political Economy, is defined by Mr. Ricardo to be "that portion of the produce of the earth which is paid to the landlord for the use of the indestructible powers of the soil. It is often however (he remarks) confounded with the interest and profit of capital, and in popular language the term is applied to whatever is annually paid by a farmer to his landlord." Mr. Malthus (*Prin. of Pol. Econ.*) defines rent to be "that portion of the value of the whole produce which remains to the owner of the land, after all the outgoings belonging to its cultivation, of whatever kind, have been paid, including the profits of the capital employed, estimated according to the usual and ordinary rate of the profits of agricultural capital at the time being." The origin and progress of rent will be subsequently considered.

The chapter on rent, in the 'Wealth of Nations,' though abounding in important facts, is, in respect to the author's conclusions, generally regarded as the most erroneous and defective in that work; it contains no distinct enumeration of the nature and causes of rent, although, it is remarked, he appears in some instances to have contemplated the subject in its true light. Other writers have treated the question in the same way, without more clearly elucidating it. The economists of the school of Quesnay have taken many just views of the nature of rent, but have equally failed in deducing from them the inferences to which they obviously led. Dr. James Anderson [ANDERSON], in the 'Recreations in Agriculture' (vol. v., p. 401), published in

1801, is acknowledged to have propounded the theory of the origin and progressive increase of rent as now generally recognised; but his theory excited little attention at the time; and it was not until 1815 that it was more fully and elaborately treated in two works published simultaneously: one of them was an 'Essay on the Application of Capital to Land,' by a Fellow of University College, Oxford (Mr. West, a barrister, afterwards chief-justice of Bombay); the other work was by the late Mr. Malthus, and was entitled 'An Inquiry into the Nature and Progress of Rent.' The late Mr. Ricardo had adopted the principles of these two works several years before they were published, but it was not until 1817 that a pamphlet by him appeared in which their truth was forcibly and clearly demonstrated. The publication of his 'Principles of Political Economy and Taxation,' in the same year, may be considered as having established all the main points included in the theory of rent. This theory, and that of Mr. Malthus on population, are undoubtedly the most important additions which have been made to the science of political economy since the publication of the 'Wealth of Nations' in 1775. But although the fundamental principles of the theory of rent are now generally considered as settled, there are several subordinate parts of the question on which political economists are at variance. Mr. Mill and Mr. MacCulloch have more fully adopted the Ricardo theory than any other writers; but Mr. Malthus has dissented from some of its principles, although his views in the main coincide with that theory; and Professor Tucker, of the university of Virginia, dissents from it still more widely than Mr. Malthus. Mr. Senior, while condemning some of Mr. Ricardo's reasonings, appears to have again propounded them under a different form.

The causes of the ordinary excess of the price of raw produce above the cost of production, as enumerated by Mr. Malthus, are:—1, That quality of the soil, by which it can be made to yield a greater quantity of the necessaries of life than is required for the maintenance of the persons employed on the land. This is the foundation of rent, and the limit to its possible increase. 2, The second quality consists in that property peculiar to the necessaries of life, by which, if properly distributed, they create demanders in proportion to the quantity of necessaries produced. Thus, the effect is to give a value to the surplus of necessaries, and also to create a demand for more food than can be raised on the richest lands. 3, The comparative scarcity of fertile land; a circumstance which is necessary to separate a portion of the general surplus into the specific form of rent to a landlord. As most modern economists have adopted the main principles of the Ricardo theory, we here give an outline of it, in the words of Mr. Ricardo.

Mr. Ricardo says:—'If all land had the same properties, if it were boundless in quantity and uniform in quality, no charge could be made for its use, unless where it possessed peculiar advantages of situation. It is then because land is of different qualities with respect to its productive powers, and because, in the progress of population, land of an inferior quality, or less advantageously situated, is called into cultivation, that rent is ever paid for the use of it. When, in the progress of society, land of the second degree of fertility is taken into cultivation, rent immediately commences on that of the first quality, and the amount of that rent will depend on the difference in the quality of these two portions of land. . . . With every step in the progress of population which shall oblige a country to have recourse to land of a worse quality to enable it to raise its supply of food, rent on all the more fertile land will rise. . . . If good land existed in a quantity much more abundant than the production of food for an increasing population required, or if capital could be indefinitely employed without a diminished return on the old land, there could be no rise of rent; for rent invariably proceeds from the employment of an additional quantity of labour with a proportionally less return.'

Rent, according to the definition which has been given, consists of a surplus which remains after the capital expended in production has been replaced with ordinary profits. This surplus, which constitutes rent, arises, as Mr. Ricardo asserts, from, and is in proportion to, the necessity for resorting to inferior soils or employing capital on the old soil with smaller returns. To use the words of Mr. Mill, his friend and disciple—'Rent is the difference between the return made to the more productive portions and that which is made to the least productive portion of capital employed upon the land.' In a country containing, as every country does contain, land of various degrees of fertility, rent therefore will not be paid until the demands of an increasing population have rendered it necessary to have recourse to the inferior soils. 'Thus (continues Ricardo), suppose land, Nos. 1, 2, 3, to yield, with an equal employment of capital and labour, a net produce of 100, 90, and 80 quarters of corn. In a new country, where there is an abundance of fertile land compared with the population, and where therefore it is only necessary to cultivate No. 1, the whole net produce will belong to the cultivator, and will be the profits of the stock which he advances. As soon as population had so far increased as to make it necessary to cultivate No. 2, from which 90 quarters only can be obtained after supporting the labourers, rent would commence on No. 1; for either there must be two rates of profit on agriculture, or ten quarters or the value of ten quarters must be withdrawn from the produce of No. 1 for some other purpose. Whether the proprietor of the land or any other person cultivated No. 1, these ten quarters would equally constitute rent; for the cultivator of No. 2 would get the same result with his capital, whether he cultivated No. 1, paying ten quarters for rent, or continued to cultivate No. 2, paying no rent. In the same manner it might be shown, that when No. 3 is brought into cultivation, the rent of No. 2 must be ten quarters, or the value of ten quarters, whilst the rent of No. 1 would rise to twenty quarters. . . It often and indeed commonly happens that before Nos. 2 and 3, or the inferior lands, are cultivated, capital can be employed more productively on those lands which are already in cultivation. . . In such case, capital will be preferably employed on the old land, and will equally create a rent; for rent is always the difference between the produce obtained by the employment of two equal quantities of capital and labour. If with a capital of 1000*l.* a tenant obtain 100 quarters of wheat from his land, and by the employment of a second capital of 1000*l.* he obtain a further return of 85, his landlord would have the power, at the expiration of his lease, of obliging him to pay 15 quarters, or an equivalent value for additional rent; for there cannot be two rates of profit. If he is satisfied with a diminution of 15 quarters in the return for his second 1000*l.*, it is because no employment more profitable can be found for it. . . In this case, as well as in the other, the capital last employed pays no rent. For the greater productive powers of the first 1000*l.*, 15 quarters is paid for rent; for the employment of the second 1000*l.*, no rent whatever is paid. If a third 1000*l.* be employed on the same land, with a return of 75 quarters, rent will then be paid for the second 1000*l.*, and will be equal to the difference between the produce of these two, or 10 quarters; and at the same time the rent of the first 1000*l.* will rise from 15 to 25 quarters, whilst the last 1000*l.* will pay no rent whatever.' (Ricardo's *Prin. of Pol. Econ.*, 3rd ed.) Perhaps however the clearest definition of this theory of rent is that given by Mr. Mill in his 'Elements of Pol. Econ.,' 3rd ed.

There remains to be noticed another incident of rent, namely, that it does not form a part of the cost of production. Mr. MacCulloch has given the shortest explanation of this law in Note iii. of his edition of the 'Wealth of Nations.' 'The price of raw produce,' he remarks, 'does not exceed the cost of production,' including in that expression the ordinary profits of the producer's capital. 'The aggregate price exceeds the aggregate cost of production; but this is because the cost of production is unequal. The price exceeds the lowest, but not the highest cost of production: and this highest cost, since it regulates the price of the whole, may be considered, without impropriety, as the cost of the whole, and the rent to be a peculiar privilege of favoured individuals.'

The circumstances which precede or accompany the cultivation of inferior lands or the employment of additional capital on the old lands are—1, an increase of population; 2, the accumulation of capital; 3, a rise in the exchangeable value of raw produce. The two first cause a fall in profits and wages, and a rising market-price of raw produce is a consequence of more labour or more capital being required to produce it, or of a deficient supply previous to its being produced. In a new country, the whole produce is divided between the capitalists and labourers, and so long as fertile land is in abundance and may be had for an almost nominal price, nobody will pay a rent to a landlord, and profits and wages are maintained at a high rate. But capital accumulabor and wages decrease; and whenever agriculture has reached a state in which the returns of additional capital on the old lands are less than could be obtained from the inferior land, such inferior land will be cultivated, and if the profits of the capital employed on such inferior land were 20 per cent., while the old lands yielded 30 per cent., a rent would arise equivalent to the difference, or 10 per cent. This, as well as any subsequent rise of rents, is caused by more capital being ready to be laid out on the old lands, but which cannot be so employed without diminished returns, and this circumstance renders it more profitable to take fresh lands into cultivation, though of an inferior degree of fertility.

One of Professor Tucker's objections to the Ricardo theory of rent is directed against the assumption that 'the means of subsistence are a fixed quantity, or near it, instead of its admitting of such gradations that a labourer may be supported by one-fifth of the soil once required for subsistence;' and he points to the western states of the American Union, where a labourer can earn in less than ten days as much grain as he can consume in a year, and where consequently a very high scale of diet is maintained, and he contrasts it with other countries in which the whole of the year's labour is necessary to earn subsistence for the year, although the scale of diet is comparatively low. In the Atlantic states of the Union, as compared with the Western states, the contrast is also very striking. This varying character of human subsistence, Professor Tucker contends, may be a cause of rent, without either an increase or decrease in the returns to capital. The very high rents paid in Ireland may be partly attributed to this cause. In the course of his objections to Mr. Ricardo's theory, Professor Tucker remarks:—'Land is a productive machine, which but a few possess, but whose produce none can dispense with, and for which there being more and more demanders, they must and will give more and more of their labour to obtain it. . . . Rents, having once begun, continue to increase with the increase of population and the more frugal consumption to which it impels individuals.' Mr. MacCulloch simply regards the adoption of a less costly food by the labourers as similar in its effects upon prices and rents to an improvement in agriculture. Professor Tucker's further objections against the Ricardo theory consist in its ascribing 'the progressive rise of raw produce and of rents to the greater amount of labour expended on the soil last cultivated, and not to the greater cheapness of all labour from the increase of population;' and in its maintaining that 'when raw produce rises, labour also rises' (p. 130). He concludes, 'that neither is a resort to soils of inferior quality, to lands more distant from market, nor different outlays of capital on the same lands, necessary either to the existence of rent, or to its progressive increase, but that it is caused solely by the increase of population, together with the capacity which the same soil possesses of supporting a greater number by reason of their resorting to a more frugal mode of subsistence' (p. 121). It should be observed, that Professor Tucker admits that 'successive resorts to inferior soils, or outlays of fresh capital on old lands, keep pace with the rise of raw produce, and ordinarily afford a *measure of the progress of rent*, and of its different degrees, according to diversities of fertility, culture, or distance from market, but they are not the cause of its rise' (p. 113). Indeed, whatever may be the true theory of the causes and amount of rent in any given community, it may be very easily shown that the existence of soils varying in fertility is not a necessary element to the existence of rent, while the limited amount of productive soil is a necessary element.

Advantages of position, such as a proximity to markets, may counterbalance the disadvantage of barrenness, and land of this description, which, if it were farther removed, would yield no rent, will, under these circumstances, produce a higher rent than more fertile lands situated at a distance from the same market. Land in the neighbourhood of towns yields a high rent, and a still higher rent is paid for land in towns. The rent in each of these cases is regulated either by the common principle that there cannot be two rates of profit, of which the case first mentioned is an instance; or, as in the latter examples, it is determined by the limited extent of such land.

Restrictions on the importation of grain, by forcing the inferior soils into cultivation, undoubtedly tend directly to raise rents; but no possible quantity of imported produce could have any material effect in diminishing the total rents of the country. Importation necessarily implies the existence of high prices in the importing country; it has a tendency to equalise rather than to lower prices, as, by facilitating the exchange of manufactured goods for common food, population is increased, and an increased demand arises for other products of the soil besides bread corn. This has been the case in the territory of Genoa, where the soil, though of a sterile nature and unfit for the production of corn, yields a higher rent than the fertile corn-lands in the plains not far distant; for the cost of production being low by means of the low price of imported food, land may be cultivated for various agricultural objects and yield a rent which, if employed in the production of grain, would scarcely repay the cost of production. In a country which possesses superior manufacturing resources and capabilities, the exchange of manufactures for common food may therefore be a cause of rent without resorting to inferior soils.

Mr. Ricardo regarded the owners of land in the same light as the possessors of a monopoly, advantageous to themselves and proportionably injurious to the mass of consumers. Mr. Malthus proposed to modify this view of their advantages, and to consider them as originating only in a 'partial monopoly.' The former is accused of underrating the national importance of rents, and Mr. Malthus of overrating them. Under a system of free importation of the produce of the soil, it may be correct to consider the owners of land as possessed only of a 'partial monopoly,' but it is scarcely so when laws are passed which, except in seasons of high prices, prohibit the supply of provisions from foreign countries; and in this case the interests of the community do not coincide with that of the owners of land.

When the rights of property are fully established, rents will exist, whether they accrue to the farmer-proprietor or are paid by the farmer-tenant to a landlord. That quality of land which terminates in rent, Mr. Malthus regards as a boon most important to the happiness of mankind, and the main security against the time of the whole society being employed in procuring mere necessaries. 'This,' he observes, 'is the source of all power and enjoyment; and without which, in fact, there would be no cities, no naval and military force, no arts, no learning, none of the finer manufactures, none of the conveniences and luxuries of foreign countries, and none of that cultivated and polished society which not only elevates and dignifies individuals, but which extends its beneficial influences through the whole mass of the people.'

In Mr. Malthus's 'Principles of Pol. Econ.' the subject of section 7, chap. iii., is 'On the causes which may mislead the landlord in letting his lands, to the injury both of himself and the country.' Most of the considerations which he urges are of a practical nature, and relate to rent in agriculture. On this part of the subject the reader may refer to Grainger and Kennedy, 'On the Tenancy of Land in Great Britain.'

(Ricardo, Malthus, Mill, and MacCulloch's *Treatises on the Elements and Principles of Political Economy*; Professor Tucker's *Laws of Wages, Profits, and Rent investigated*, Philadelphia, 1837; Professor Jones's *Essay on the Distribution of Wealth and on the Sources of Taxation*.)

RENT (in Law Latin, *redditus*, 'a return') is a right to the periodical receipt of money or something valuable in respect of lands or tenements held by him from whom the rent is due. There are three kinds of rent—rent-service, rent-charge, and rent-seck.

There is rent-service when a tenant holds lands of his lord by fealty and certain rent, or by homage, fealty, and certain rent, or by other services and certain rent. Rent-service therefore implies tenure, and it may be due to the lord of the manor of which the lands are held, or to some other chief (that is, immediate) lord of the fee, or in the reversioner. The right of distress is an incident to rent-service in arrear, so long as it is due to the same person to whom fealty is due. Before the statute of Quia Emptores (18 Edw. I.), a person might make 'a feoffment in fee simple either by deed or without deed, yielding to him and his heirs a certain rent, which was a rent-service, and for this he might have distrained of common right; and if there were no reservation of any rent, nor of any service, yet the feoffee held of the feoffor by the same service as the feoffor did hold over of his lord next paramount.' (Litt., 216.) The statute of Quia Emptores enacted that the feoffee shall hold of the chief lord by the same services by which the feoffor held, and consequently no rent can now be reserved when a man transfers to another all his estate in land. In order that rent-service may now be created, the person to whom the rent is reserved must have a reversion in the lands and tenements out of which the rent is to issue; but any reversion is sufficient. Thus a person who has a term of twenty years may grant it to another, all but one day, and this will leave him a reversion, so that a rent-service may be reserved, with its incidents of fealty and the right of distress. If he assign all his term, reserving a rent, but without a clause of distress in the assignment, he cannot distrain for the rent.

Rent-service therefore which has been created since the statute of Quia Emptores can only be reserved to the lessor who retains a reversion, and it will belong to the person who is entitled to the reversion. If a man seised in fee simple makes a lease of lands for years, reserving rent, the rent-service is descendible to his heir with the reversion; though all rents which accrue due to the lessor before his death will belong to his personal representatives. A rent-service reserved out of chattels real will of course belong to the personal representatives of the lessor. A rent is now most commonly reserved in leases for years, but it may be reserved on any conveyance which passes or enlarges an estate; and it may be reserved in the grant of an estate in remainder or reversion, or in a grant of a lease for years to commence at a future time.

A rent-service may be separated from the reversion or seignory, by the reversioner granting the rent and retaining the fealty: in this case the lands are still held of the grantor, but the rent is due to the grantee; not however as rent-service, but as rent-seck (redditus siccus), so called, 'for that no distress is incident to it.' (Litt., 218.) If the seignory or reversion is granted, the rent-service will pass by the grant, and the grantee is entitled to receive the rent from the tenant from the time that he gives him notice of the grant, together with all rent that had accrued due since the grant, and is unpaid at the time of such notice.

Rent-service can only be reserved to the feoffor, donor, or lessor, or to their heirs, upon any feoffment, gift, or lease; and if rent is reserved generally, without specifying the persons, it will belong to the lessor, and after his death to those who are entitled to the reversion. Rent is payable at the times mentioned in the reservation, but not till the last minute of the day on which it is payable.

When rent-service is in arrear, the common-law remedy for the recovery of it is by distress. [DISTRESS.] By 4 Geo. II., c. 28, s. 2, every landlord who by the terms of his lease has a right of re-entry in case of non-payment of rent, may, when half a year's rent is due, and there is no sufficient distress on the premises, serve a declaration in ejectment on his tenant, without any formal re-entry or previous demand of rent, and a recovery in such ejectment is final and conclusive, unless the rent and all costs are paid within six calendar months after the judgment in the action of ejectment has been executed. The action may also be stayed before trial, if the tenant will pay or tender to the lessor, or pay into court, all the rent then in arrear, together with the costs. By the common law the lessor has also an action of debt for rent against a lessee for years or at will; and by the statute of Anne (8, c. 14, s. 4) there is also the same action against a lessee for life during the continuance of his estate, which had previously been given for arrears of rent after the determination of the estate (32 Hen. VIII., c. 37). A lessor may also have an action of covenant for rent, either by force of the implication contained in such words as 'yielding and paying' rent, or by force of an express covenant to pay, which is seldom omitted in any lease. If the lessee assign his interest in the term, he, and his executors so far as they have assets, are still liable under the covenants to the person entitled to the reversion. The assignee also becomes bound by such of the covenants as run with the land, and is consequently liable to an action upon them. There is also the remedy by action of assumpsit or debt for the use and occupation of land, which action lies without any express agreement for rent.*

Rent-service may be discharged in various ways. If the tenant be evicted from the lands demised to him, he is discharged from payment of the rent; and if the lessor purchase the lessee's interest, the rent is also discharged. The lessor may release a part of the rent-service, without releasing the whole.

If the person entitled to the rent-service purchases part of the interest in the land in respect of which rent is due, the rent-service is apportioned according to the value of all the land, and accordingly the tenant is discharged from payment of rent in respect of the part purchased. The person entitled to the reversion may also grant his interest in part of it, and the rent will be apportioned between him and his grantee; for the interest in the reversion is of a divisible nature, and the rent follows the reversion. If the lessee should be evicted out of part of the lands, there will also be an apportionment. Before the late alterations of the law, when the moiety of a reversion was extended on an elegit, the rent was apportioned, and the lessor consequently retained half of it. If a widow is entitled to dower of a reversion, she is also entitled to one-third of the rent reserved upon a lease for years made by her husband.

At common law, if a tenant for life died before the rent became due, which was reserved on a lease that determined by the death of the tenant for life, his personal representatives could not claim an apportionment of the rent, nor could the reversioner or remainder-man claim such portion as accrued due during the life of the tenant for life. But such an apportionment was given to the personal representatives by stat. 11 Geo. II., c. 19, s. 15. The act 4 and 5 Wm. IV., c. 22, extends the provisions of this act to rents reserved on leases that determine on the death of the persons who make them, though they are not strictly tenants for life, and on leases of lands held *pur auter vie;* and by the said act all rents-service reserved on any lease by a tenant in fee or for any life interest or under any power, and granted after the passing of this act, and all rents-charge and other rents, annuities, &c. made payable under instruments executed, or (being a will) coming into operation after the passing of the act, shall be apportioned, and a proportionate part thereof, from the last time of payment to the day of the death of the party interested therein, paid to the personal representatives of such party.

A rent-charge is a rent granted out of land either at common law or by the Statute of Uses, with a power of distress for the recovery of the rent. Such rents may be created by the owner of the land who retains the property of it; and they may also be reserved on the alienation of the land. These rents differ from rent-service in not being connected with tenure, and the remedy by distress is therefore not an incident to rent-charges, but is created by the same instrument which creates the rent-charge. If no power of distress is given, the rent is a rent-seck. Rent-charge may be created either by deed or by will. Sometimes, by the terms of the grant, the grantee of a rent-charge is empowered to enter on the land and satisfy himself for all arrears out of the profits of the land. When a rent-charge is created under the Statute of Uses (s. 4, 5) with a power of distress and entry upon the land in case of arrear, the person to whom the rent-charge is given obtains the legal estate in the rent-charge, with all the remedies for its recovery, as he would by a direct grant of the rent-charge; and the same instrument (lease and release) which creates the rent-charge may also make a settlement of the lands charged with the rent. In this way in a marriage settlement a rent-charge may be provided for the wife's jointure.

An estate in a rent-charge may be either in fee simple, in fee tail, for lives, or for years, according to the terms of the original limitation. A rent-charge of inheritance is real estate, and descendible to the heir; but a payment that is due belongs to the person representative. There may also be an estate in fee simple in a rent-service created before the statute of Quia Emptores. A rent-charge in fee simple is subject to curtesy and dower; and also a rent charge in tail. But if a rent-charge be created and granted to a man and the heirs of his body, his surviving wife will not be entitled to dower if the husband dies without issue. Until the 3 and 4 Wm. IV., c. 106, a woman was not entitled to dower out of a rent-charge, unless her husband had the legal estate in it. A rent-charge may be limited by way of remainder; and a new rent-charge may be created to commence at a future time.

A rent-charge may be discharged in various ways. If a man who has a rent-charge out of certain lands buys any part of them, the whole rent is discharged, for it issues out of the whole of the lands; and the consequence is the same if he releases all his right in any part of the land. But a man may release part of the rent-charge without affecting the remainder; and a division or apportionment of a rent by conveying part of it to a stranger is a valid conveyance. If part of the lands which are subject to the rent-charge de-

* See a remark on this action, 6 A. and E., p. 839.

ground to the grantee, the rent will be apportioned according to the respective value of the two parts of the land.

A rent-seck, as already mentioned, is not, like rent-service, accompanied with a right to distrain at common law; but by the stat. 4 Geo. II., c. 28, s. 5, this distinction in respect of remedy between rent-service and rent-seck, created since that statute, is abolished; and the act also applies to rent-seck created prior to the statute which had been duly paid for three years out of the last twenty years. Other rents, though they belong to one of the three divisions above mentioned, are often distinguished by particular names: thus the rent due from a freeholder is called a chief rent (reditus capitalis); the rents of freeholders and ancient copyholders of manors are sometimes called rents of assize, being certain, or ascertained, and also quit rents (quieti redditus), because they are a quittance and discharge of all services.

A fee-farm rent is properly a perpetual rent-service reserved by the crown, or, before the statute of *Quia Emptores*, by a subject, upon a grant in fee simple. The purchaser of fee-farm rents originally reserved to the crown, but sold under 22 Car. II., c. 6, has the same power of distress that the king had, and so may distrain on other land of the tenant not subject to the rent.

By the stat. 42 Geo. III., c. 116, in cases where the land-tax has not been redeemed in due time by the owner of the land, it may be purchased by any other person, to whom it will belong as a perpetual rent-charge (though it is called a fee-farm rent in the Act), and the purchaser will have all the remedies for rent reserved on a lease.

By the 3 & 4 Wm. IV., c. 27, s. 42, no arrears of rent or of interest in respect of any sum of money charged upon or payable out of land or rent, or any damages in respect of such arrears of rent or interest, shall be recovered by any distress, suit, or action, but within six years next after the same respectively shall have become due, or some acknowledgment in writing given to the person entitled thereto by the person by whom the same was payable; except where there has been a prior mortgagee or other incumbrancer in possession of any land or receipt of the profits thereof within one year next before an action or suit shall be brought by a subsequent mortgagee &c.; and then the arrears of interest may be recovered for the whole time such prior mortgagee, &c. was in such possession or receipt.

REO'PHAX. [FORAMINIFERA, vol. x., p. 347.]

REPEATING CIRCLE. The principle of repetition from which this circle has its name was first explained by Tobias Mayer, professor of the university of Göttingen, in *Commentarii Societatis Regiae Scientiarum Gottingensis*, tom. ii., p. 325, for the year 1752. Mayer found that the common surveying instruments were often inaccurate in 2°, while the quadrant, then used in all great scientific surveys, was, from its weight and price, and the trouble required for verifying and adjusting it, scarcely to be considered a portable instrument, but only fit for the observatory. The substitute which he proposed for geodesical purposes may be described briefly as follows:—Suppose a hollow tube fitting upon an axis, to which it can be clamped, when required, by a screw; the axis itself is fixed on the top of a staff. This part of the instrument is exactly similar to a common mounting for surveying compasses, &c., where greater stability is wanted than a ball and socket will give. On the top of the tube a flat bar is screwed, the plane of which is horizontal when the tube and axis are vertical; the bar and tube thus form one piece, which has the shape of a T. A second bar of the same length is placed exactly above the former. This latter bar moves easily, and without shake, on a pin concentric with the tube and axis, and thus can be placed at any angle with the fixed rule, and, as it is supposed, without at all disturbing it. Two fine dots are pricked towards the ends of each bar; the lines joining the dots in each should pass exactly through the axis of motion of the upper bar, and the dots must be equidistant from the centre. When this is so, the four dots will, in every position of the bars, be the angular points of a rectangle, and the equality of the opposite sides can be ascertained by measuring the distance with compasses. Finally, on the top of the upper bar a telescope with cross wires is fixed, the telescope being a little shorter than the bar, that it may not interfere with measurements between the dots.

The mode of measuring an angle with this instrument is as follows:—Let the two objects be R (that to the right) and L (that to the left). Set the fixed bar to some angle from ten to twenty degrees to the right of R by the motion of the tube on the axis, and clamp the axis-screw firmly; then, by the motion of the upper bar alone, bisect R with the telescope. Take, with a pair of compasses, the distance between the dots, apply the distance to a scale of chords, and you have the angle between the fixed bar and the object R. Call this angle θ. Now, by the motion of the upper bar alone, bisect the object L. It is clear that if the distance between the dots were again measured, and the angle deduced, as before, from the scale, we should have a measure of the angle required $+\theta$. But instead of measuring at present, let the telescope be brought back on R, *by unclamping the axis screw and moving the whole instrument on its axis*: when this is satisfactorily performed, clamp the axis, and bisect L exactly as before, by moving the upper bar and telescope alone. The angle between the bars as deduced from measuring the chord between the dots will now clearly be twice the angle required $+\theta$. Let the operation be performed so many times, eight for instance, that the bars are nearly in their original position with regard to each other, and let the distance between the dots be measured and the corresponding angle be deduced from the scale of chords, which suppose to be ϕ, ϕ being larger than θ. If this last-mentioned angle had been θ exactly, it is clear that the bar would have come round exactly to its original position after having moved through 360°, but as it has besides moved over an angle $=\phi-\theta$, the whole angle moved through is $360°+\phi-\theta$, which is also eight times the angle to be measured; hence the angle subtended at the spectator by R and L is $\frac{1}{8}(360°+\phi-\theta)$. By continuing this process of stepping several times round, there seems to be no limit to the accuracy with which an angle can be measured, except that which depends on the imperfection of the telescope, the indistinctness of the objects, or the uncertain lateral effect of terrestrial refraction. Mayer used a scale of chords, probably because he was thus able to construct the instrument himself, and could dispense with any circular arc or divisions. We do not see that he has noticed one slight inaccuracy, viz. that as the dots lie in different planes, the distance between them is not the actual chord of the angle required, but is the hypothenuse of a right-angled triangle, the altitude of which is the thickness of the upper bar, while the base is the chord required; but this error is easily allowed for, and, when the angle to be measured by the compasses is of a tolerable size, is scarcely worth considering. If we conceive the plane of the lower bar extended and changed into a divided circle, while the upper bar becomes a vernier at each end, we should probably have the instrument Mayer would have proposed, had it been in his power to employ a tolerable mathematical-instrument maker. Mayer says that he invented this instrument eight years before the publication of his memoir.

The reward proposed by the English parliament for any means by which the longitude at sea could be determined, stimulated Mayer to perfect the method of lunar distances. For the successful solution of this problem two things are required—tables correct enough to predict the true place of the moon at any future time, and an instrument for measuring the distance between the moon and star with sufficient accuracy. Mayer fulfilled the first condition by his celebrated Lunar Tables, one copy of which was sent to the lords of the admiralty in 1755, and a later, improved up to his death (1762), forwarded by his widow in 1763.* For measuring the distance between the moon and star he proposed an instrument similar to Hadley's sextant, but in which the angle can be repeated or multiplied without intermediate readings off, similar in principle to the instrument just described.

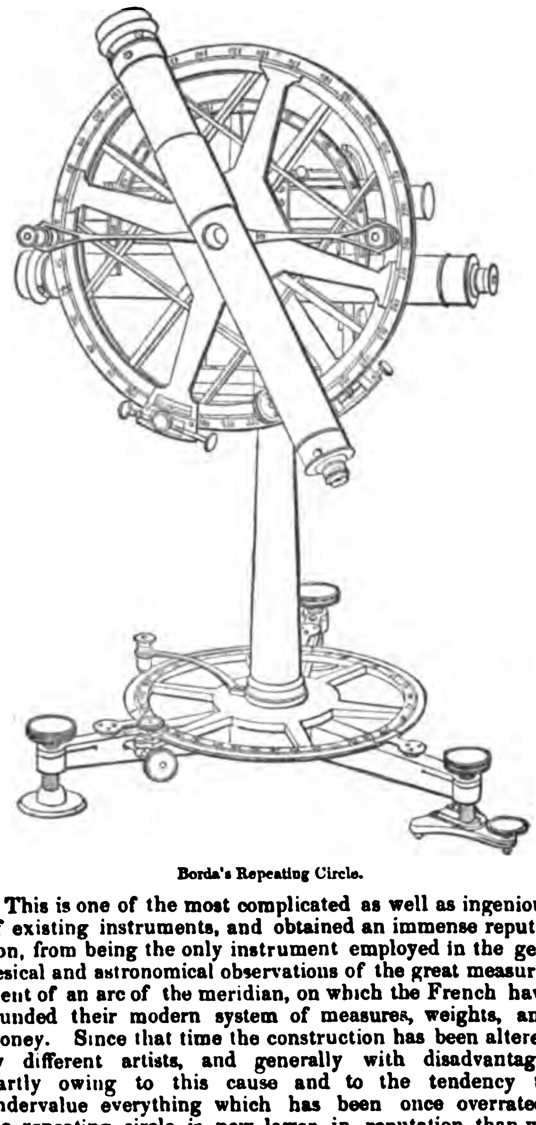
Mr. Troughton says (article 'Circle,' Brewster's *Cyclopædia*) that Bird was employed to make reflecting circles after Mayer's idea, but his dividing was so excellent, that the entire circle was thought useless, and the sextant preferred, as having a larger radius, and being lighter and handier.

In 1787 the Chevalier de Borda published his '*Description et Usage du Cercle de Réflexion*,' in which he proposed a modification of Mayer's circle, so slight that at first sight it would almost seem trivial, but which gives an unquestionable superiority to the above every other form of reflecting instrument when well made and skilfully and *perseveringly* used. We shall return to Mayer and Borda's construction of the repeating reflecting circle in article Sex-

TANT, as they cannot be understood until the principle of reflecting instruments has been explained.

The date of the invention of the repeating circle which is the proper subject of this article, is somewhat uncertain: it is later than that of the reflecting circle. One was constructed in 1787, and employed in connecting the meridians of Paris and Greenwich. (See *Mém. de l'Acadêm.*; a Memoir by Le Gendre, 1797; and a Memoir by Cassini, 1798.) The *Connoissance des Tems*, An VI. (1797-8), contains the plate and description of a repeating circle, which was made by Lenoir for the astronomer La Lande. When the French government undertook the measurement of an arc of the meridian from Dunkirk to Barcelona, the commission to whom this operation was entrusted resolved to employ the repeating circle.

Fig. 1.



Borda's Repeating Circle.

This is one of the most complicated as well as ingenious of existing instruments, and obtained an immense reputation, from being the only instrument employed in the geodesical and astronomical observations of the great measurement of an arc of the meridian, on which the French have founded their modern system of measures, weights, and money. Since that time the construction has been altered by different artists, and generally with disadvantage. Partly owing to this cause and to the tendency to undervalue everything which has been once overrated, the repeating circle is now lower in reputation than we think it merits, though it must also be admitted that the great improvements which have been made in recent years, especially on the Continent, in the graduation of small circles, has rendered one principal merit of this construction, viz. the annihilation of errors of division, comparatively of small importance. From the superior execution of English instruments at the time when Borda's circle was in its highest fame, and the dislike of our countrymen to calculation, the repeating circle was never much or successfully used in England, though several have been made.

In this figure the general form of the instrument is shown tolerably well, but some of the essential motions are at the back of the circle, and these are drawn on a larger scale in a second diagram. The whole circle turns round on the vertical column, which has an inner axis of steel with good fittings at the top and bottom. It is usual and proper to make these fittings with great care, but it is not an essential condition to accuracy in the performance of the instrument.*

The top of the column finishes in a square bar, to which the upper works and circle are firmly screwed. We shall first describe the motions which are required for astronomical purposes, and point out the rest when the geodesical properties of this instrument are considered. The azimuthal circle is scarcely to be considered a part of the instrument.

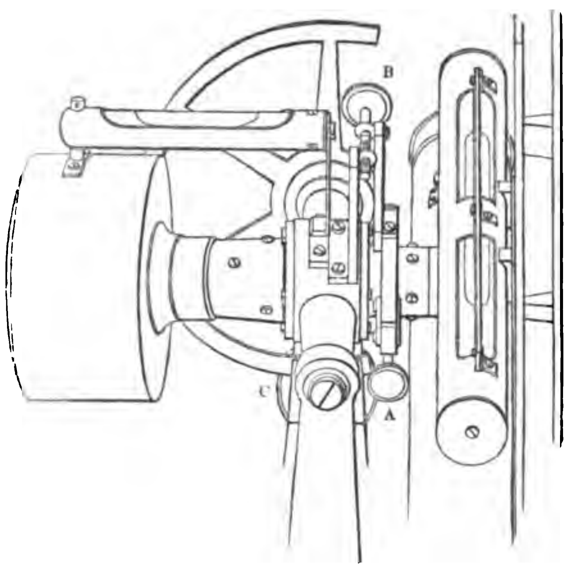
The front telescope, its verniers, and clamp, are seen distinctly in front. (*Fig.* 1.) This moves very freely on a spindle within the axis of the circle. There is a level behind, a projecting end of which is seen in the figure. This and its accompanying back telescope are—one a little above and the other a little below the axis of the circle, and revolve on a collar which works on the outside of that axis. These can be fixed in any position by a clamp (also seen in the figure) which embraces the back edge of the circle: the back telescope is for measuring terrestrial angles. Finally, the axis of the circle itself passes through a fitting, on which it also turns freely, carrying telescopes, level, &c. without altering their position in respect to itself. There is a clamp to restrain this motion and fix the circle, the head of which is seen at A, *fig.* 2, and a tangent screw for slow motion at B. This is the weakest and most inconvenient part of the instrument, for the clamp holding so near the axis of motion has little power, and there is scarcely room for getting at the screw-head, while the slow-motion clamp is out of the way of the observer when he requires it for bisection. The large weight behind is a counterpoise, and the small level above is for setting the circle vertical. There is a clamp at C, which bites on the semicircle to make this adjustment and prevent its being deranged. We will describe the process of observing with the instrument when the object is a star at or near its meridian altitude.

Supposing everything to be adjusted, *i.e.* the axis and circle both vertical, the observer bisects the star with the telescope, he or an assistant having previously brought the level nearly to the corresponding points of its scale. The level is now read off, giving it time to settle if wanted. We suppose its graduation to be in seconds, and reckoned outwards from the centre of the scale. The verniers are read off, the instrument turned half-round on the vertical axis, the telescope clamp released, and the star again bisected by the telescope, using its peculiar clamp and tangent screw; and finally, the level is again read off. This operation is precisely the same in all circles having an azimuthal motion, and it is clear that if the verniers were again read off, the difference between the first and second readings would be (after it is corrected for the indication of the level) twice the zenith distance of the star. Let the circle be now reversed, the level clamp and circle-axis clamp be released, and the whole circle moved in its plane till the telescope points to the star, and let the star be bisected again by using the axis clamp and its tangent screw only. The level must be brought back to be horizontal while this is doing, and be actually *clamped* before the final bisection of the star is made. We conceive that this must be done at twice, even by two observers; and it may be done at twice by one, though in a longer time. If the reader has fully understood the process, he will see that the instrument is precisely as at the commencement, except that the telescope and its verniers have travelled over the circle, an arc equal to twice the zenith distance of the star. A repetition of the operation will carry the telescope verniers over four times the distance, and by continuing the process the final arc read off may be made any number of times twice the zenith distance of the star. If the series stops after ten such processes, the arc travelled over is twenty times the simple zenith distance. Let the verniers be now read off, then subtracting the first reading from the last, and

* Three thousand pounds were paid Mayer's widow for these Tables in 1765; they were printed by order of the Board of Longitude, under Maskelyne's superintendence; *Tabulæ Motuum Solis et Lunæ, autore Tobia Mayer*, Londini, 1770.

* In one of the expeditions sent to explore the North-West Passage, the repeating circle was found unmanageable because the superior contraction of the brass tube over the steel axis changed the close-fitting into a tight grasp which no force could overcome. This must always have given trouble, but ought not to have thrown the instrument out of use. If the whole instrument had been lifted up and turned half round, bodily, and the level brought to its former reading, the double, quadruple, &c. zenith distances might have been observed just in the ordinary way. If the level forms one body with the circle during reversal, and keeps its zero unchanged, everything besides is nonessential.

Fig. 2.



Back of Borda's Repeating Circle.

dividing by twenty, the result will be the zenith distance of the star, and the errors of division or of reading off will also be divided by twenty. If the number of repetitions which can be taken at one culmination are not thought sufficient to destroy these errors, the series may be prolonged on the following and subsequent nights, starting from the preceding reading without disturbing the verniers, until any number whatever are taken, the only essential condition being that in reversing, the level is undisturbed both in its attachment to the circle and in its own zero; and that in bringing the telescope on the star by turning the whole on its horizontal axis, the connection between the telescope and circle is permanent. The hour, minute, and second at which each bisection is made are to be noted.

We have said that it is better to read off the level than to attempt to bring the ends of the bubble exactly to the same division, which is really an impossible condition with one observer, and scarcely practicable even with two. The differences should be as small as they can be made with moderate care and in a moderate time; but a well ground level will measure small arcs better than any graduated limb or even than any small telescope can do, and it is therefore as safe to correct for an error of level as to adjust. The level readings should be registered as towards the object end and eye end, or $-$ and $+$, along with the times, and the corrections may be made to the final arc. It is clear that if the level were always brought to the same divisions, there would be no level error. The effect of a derangement of the vertical axis, which is shown by the level, is calculated as follows:—Let the reading of the level end towards the object be $10''$ larger than the reading towards the eye. To correct this, the footscrew towards the observer should be raised $5''$, when the two readings will agree; but now the telescope points $5''$ *below* its former position, in which it bisected the star correctly. The telescope therefore must be raised, *i.e. the zenith distance must be diminished* $5''$; hence if $5''$ be subtracted from the multiplied zenith distance on account of that observation, the error will be corrected, and so on with every other instance. The rule is, add together all the level readings towards the object end, and prefix $-$; do the same with those towards the eye end, and prefix $+$; take their algebraic sum, and divide by twice the number of observations, and the result is the correction to be applied with its sign to the mean zenith distance. This will generally be a very small quantity. As the great difficulty in observing out of a regular observatory is in the reading off, the division of the level might be to every $2''$, but numbered as single seconds. These would be better seen, and the divisor of the difference would be the number of observations. When the instrument is very small, and the probable circumstances under which the observer may be placed promise few facilities, the scale may be cut to $10''$ only, with bold lines. A mistake of one or two tenths in guessing the subdivisions would be very rare, and scarcely cause a sensible error in the final result.

The circle has been supposed to be adjusted before observing; this is a very simple operation. First place the instrument with the footscrews in their cups, and let that footscrew be towards the observer which rests on the slow-motion piece. This is seen at *fig.* 1, on the right. Place the axis nearly vertical by guess, or, if there is an azimuthal circle, set the plane of that nearly horizontal by a box level. Then place the plane of the vertical circle upright by the cross level, and bring its plane to be parallel with the two footscrews which are *from* the observer; *i.e.* if the object is in or near the meridian, set the circle east and west. Bring the bubble of the main level to the same division at each end by its clamp and tangent screws, and then reverse the instrument (turn it 180° in azimuth). The level is to be brought again to the same divisions, half by its tangent screw, half by screwing the two footscrews an equal quantity in opposite directions. Now turn the circle a quarter round (place it in the meridian according to the supposition), and bring the bubble of the level to its proper position by the third footscrew only. This first attempt at adjustment need only be approximate, but it must be performed over again with considerable nicety. The slow-motion piece is, we believe, due to Borda, and is a very ingenious and useful contrivance for making a coarse screw do the work of a fine one. By placing the footscrew nearer to or farther from the line of the two studs, the elevating power of the screw can be reduced in any proportion, and the finest and slowest motion possible given to the instrument. We have used the slow motion for finally bisecting a star in observing with great comfort. It is more ready to the hand than any other part of the instrument, and the disturbance of the axis is of no importance, as the level must be read off at all events. The approximate bisection is performed by the other screws, and if the observer recollects which way the star is moving, the space through which the instrument is thus moved need only be a very few seconds. The cross level must be originally fixed and adjusted, after the plane of the circle is known to be vertical, either by hanging a plumbline before the limb, or when the telescope bisects at the same time an object and its image reflected from a fluid. When the cross level is adjusted, the horizontal wire of the telescope may be set right by making a star in the meridian run along it, or else by bisecting a fixed object with it and afterwards moving the circle in azimuth. The object should run along the wire, and by twisting the wire-plate round may be made to do so.

In the astronomical use of the instrument the azimuthal circle is scarcely required, except to see that you have turned the circle 180° at each reversal. It is convenient to have a coarse division to show this; it is a relief to the eye, and prevents the possibility of catching a wrong star. Any stop which is adjustable and gives notice when the rotation has reached 180° will do. In many of Troughton's repeating circles there is a pin which is pressed by a slight spring against two holes in the azimuth circle, which are 180° apart. This is convenient enough if the observations are confined to Polaris or a very slow moving star, but wholly insufficient for stars near the equinoctial. It supposes besides that the feet of the instrument are almost exactly placed with respect to the meridian, which is not to be done at once. A bar moving rather stiffly on the vertical axis, and coming against a stop, seems a better contrivance.

For setting to the approximate zenith distance, there is a graduated semicircle attached to the level, which may be seen in the general view. This has its diameter parallel to the level. A slender bar is attached to the object end of the telescope, and passes at the back of the circle; this points out on the semicircle the approximate zenith distance of the star. In many circles which we have seen there are two slips of brass which slide with a little force on the semicircle, and the slight bar above mentioned is brought to *touch* each of these stops alternately. Nothing can be more convenient, but unfortunately, however well the clamps may be made, the contact between the bar and a stop forces the clamp somewhat, and the essential condition of the instrument, that these should be undisturbed, is destroyed. The bar should not be allowed to touch the semicircle at all, but stand freely from it. In this way, by alternately bringing the bar to the equal and opposite divisions, when either the telescope or the level is moved, the telescope will always be at the proper altitude when the level is horizontal. If any one should wish to use the repeating circle as an altitude and azimuth circle, or as a surveying instrument, the wires of the telescope must be set at right angles to the circle axis, by bisecting a distant and distinct object, reading the azimuthal verniers, turning the instrument half round, again bisecting the object and reading the verniers a second time. If the object be very distant, the azimuth circle may be set to the mean of the readings, and the object bisected by the horizontal screws which draw the wire-plate; but if very great accuracy is required, either two marks must be set up having the same distance from each other as lies between the two positions of the axis of the telescope, or the angle which this last space subtends at the distant mark must be allowed for. The instrument is not fitted for nice observation with the azimuth circle.

We have now explained the chief astronomical use of Borda's circle, which is that of determining the altitudes of stars upon the meridian by several observations near the meridian. There is a correction to be applied to the mean result, which is easily computed when the approximate latitude and exact time are known. The formulæ and tables required may be found in several works on astronomy, in Schumacher's *Hülfstafeln*, p. 38, and Baily's *Tables*, p. 154. The length of time during which the observations may be carried on depends on the altitude of the star and its proximity to the pole. Polaris might be observed safely beyond 36^m on each side the meridian, which is the extent of the present tables, and, in these latitudes, stars in or below the equinoctial for fully half an hour on each side. It is supposed that the error of the clock is well known, but even this may be wrong to a small amount without causing much error, if the number of observations on each side the meridian and the hour angles are nearly equal.

The repeating circle may be very well used for getting the time either by equal altitudes, or by absolute altitudes with one or two repetitions. For this purpose there should be three or five horizontal wires, and the instrument should be previously carefully adjusted. The instrument must be moved in azimuth, so that the star passes each wire near the centre, and nothing should be touched which affects the level. For illumination by night, there is an opening with a reflector in the centre of the telescope. This is objected to as weakening the telescope, but the other mode of illuminating by a small central reflector, or outer ring in front of the object glass, is inconvenient. Perhaps by taking a longer hold of the telescope and strengthening the intervening portion of the tube, the former convenient arrangement may be preserved without sensible loss of strength. The repeating circle, on Borda's construction at least, cannot be well employed in observing the sun without very careful screening. The level is so perpetually changing its zero, when exposed to the sun, that there is no possibility of saying what the instrumental zenith is.

One of the first operations which the observer must engage in, is to determine the scale of his level at different temperatures, and then he may, for small deviations, use the indications of the level, instead of worrying himself and losing his time in attempting to produce a perfect adjustment. The value of the scale is thus measured:—Bring the bubble towards one end, bisect a very well defined object with the telescope, and read off both scale and verniers. Then, by the slow-motion foot-screw, bring the bubble towards the other end, bisect the object again by the telescope, and read off the level scale. Now bring the bubble to its original position by the circle-axis clamp, and the telescope on the object by its own clamp, when everything is as at starting, except that the telescope has moved over the circle the sum of the angular motions pointed out by the level. This may be repeated till a sufficiently accurate value is got for the *whole* scale. To try the equality of the divisions of the level, place the foot-screw near the line passing through the studs of the slow-motion piece, and note the motion of the level for every *whole* revolution of the screw. Opticians of character are generally very careful about their levels and scales, but the practical astronomer should never trust where he can have proof.

We shall speak as briefly as possible on Borda's circle as a geodesical instrument, although it is an excellent surveying instrument, as the great French survey proves, but the same advantages can be obtained by a different application of the repeating principle. On looking at *fig.* 2, it will be seen that the whole of the upper circle, with its counterpoise, &c., revolves on a horizontal axis, and, by the two motions round the vertical and the horizontal axis, it is evident that the plane of the circle can be made to pass through any two points on the earth's surface. There is a little address and practice required to do this quickly and correctly, but it is easily learned. When it is effected, the adjustment will remain undisturbed to the end of the series of observations. The middle wire of the front telescope is supposed to have been adjusted perpendicular to its axis, and the middle wire of the back telescope may be adjusted similarly, or, what will do as well, may be made to bisect a very distant mark at the same time with the front telescope. The circle, being placed in the plane of the two objects, is clamped, and one observer bisects R, the right hand object, with the front telescope, while the assistant bisects L with the back telescope. Now release the circle-axis clamp, and move the circle round in its own place until R is bisected by the back telescope, clamp the circle again, and bisect L with the front telescope. It is clear that the front as well as the back telescope has been carried on to the right through the angle to be measured by the motion of the circle, and, therefore, when the front telescope is brought back to R, and over to L, that it has travelled over the face of the instrument twice the angle to be measured, which is therefore equal to the difference of the readings before and after the operation. Release the circle again, bring the front telescope to R by the general motion of the circle, and the back telescope on L by its own proper motion: the instrument is now in its original position, except that the divided circle has revolved as it were from right to left in its own plane (which also passes through the two objects L and R) twice the angle to be measured. By repeating the above process the motion given to the circle is four times the angle to be measured, and so on, the number of repetitions being only limited by the patience of the observers and the time they can bestow on their work. The repeating circle used thus is a very powerful instrument. As the angles in an accurate survey are never very small or very large, a little defect in the plane of the instrument or a slight non-parallelism between the planes of the two telescopes is of little injury, though, from the poor centring of the back telescope, defects of this nature are unavoidable. As both telescopes may be, and the back telescope always is, eccentric, there is a reduction to be applied to the angle on this account. Whoever wishes for a full account of these and similar reductions will find it in Delambre's *Méthodes Analytiques pour la Determination d'une Arc du Méridien*, &c., Paris, An VII.; in the *Discours Préliminaire*, by the same author, contained in the *Base du Système Métrique Décimal*, vol. i., Paris, 1806; and in almost any modern French geodesical work. There is a very full account of the repeating circle, with all its verifications, &c., in the second volume of the last-mentioned work, pp. 160 *et seq.*, and the four volumes will supply examples of every kind of observation and reduction. As a geodesical instrument however the repeating circle of Borda has gone completely out of use, and probably for ever.

Borda's repeating circle possesses two most valuable properties: mere errors of division may be diminuted by sufficient patience; and the fatigue of reading off the divisions, the most ungrateful part of an observer's task, is greatly reduced. Hence, it may be asked, why is not the repeating circle in general use as a portable astronomical instrument? We should answer that, in the first place, the construction of Borda is by no means satisfactory for an *astronomical* instrument; it is weak, and heavy, and rickety. But if a *portable* astronomical circle is wanted, and to this class of instruments we should confine the repeating circle, we think the following alteration should be adopted. The telescope hangs loosely from its centre,* and whatever care may be taken by the artist, the flexure of each end must be considerable, probably different, and possibly varying from time to time with variations in the temperature. It should be

* If the object and eye end bend equally, there is no alteration in the direction of the line of sight; the only evil is that the oblique incidence of the rays on the object glass deforms the image when the obliquity is considerable. The German artists of Reichenbach's school apply levers to telescopes [illegible] by the middle, in order to counteract flexure. We prefer, on the whole, obtaining a maximum of stiffness, and then determining the effect of flexure, which must be allowed for. There is no possibility of avoiding the investigation in any case where accuracy is demanded. Gambey takes a longer hold of the telescope, but in providing a motion for surveying when the circle is horizontal, we think he has lost something in stability when the circle is vertical.

grasped by two strong collars near the ends of a diameter of a vernier circle, and the telescope might then be safely extended three or four inches each way beyond the divided circle. Again, the axis clamp which holds the vertical circle should be fixed on the pillar and embrace the rim of the inner circle, the clamp of the level (for no second telescope is wanted) might be at the back, above, and quite out of the way. The whole circle should be brought as close to the upright pillar as possible, and perhaps its axis had better be fixed by the maker permanently at right angles to the pillar. This would take away much weight and give great firmness to the whole instrument.

It must however be admitted that unless there are two intelligent observers, or unless the base on which the instrument stands is so steady as to prevent the possibility of any derangement when the observer moves from the telescope to read the level, that errors may creep in, though not, as it seems to us, greater than in all other instruments not reflecting. We have previously cautioned circle observers, and the warning cannot be too strongly pressed upon our countrymen at least, that the *level* must *always* be noted contemporaneously with the *bisection* of the star. If the foundation of the instrument is immoveable, this will be the same as the level a minute after bisection, and so only one observer be required. But if the position of the instrument is affected by the weight or motion of the observer, the *level* after bisection is no test of the position at bisection, and two observers are absolutely necessary. In Borda's repeating circle, where the clamp is necessarily imperfect from the shortness of its bearing, it is impossible to move the front telescope without shifting the circle a little at the same time; but this is of no importance, for the level shows the change, and the reading off of the level, when properly applied, *corrects* this error.

It is precisely from not thoroughly considering this fundamental principle in the repeating circle, that the French, and, we believe, German artists, made an alteration in its construction, which introduced larger errors than previously existed. They applied the level not to the circle itself, but to the vertical column, which is, in truth, a much more convenient situation. Now if the clamp which holds the circle while the telescope is moved, were absolutely perfect, the result would be the same as if the level were attached to the circle; but suppose the clamp to yield a little, and it is clear that the angular motion of the circle causes an error in the observation, which is not pointed out by the level. In some instruments of this construction (*à niveau fixe*) the polish of the surface to be clamped was so fine that the clamp allowed the circle to slip very readily. Indeed it is easy to see, on theoretical grounds, that if there is any tendency to yield, no clamp is to be relied upon against a very small degree of force acting perpendicularly to its grasp. It is evident on consideration that Borda's repeating circle depends almost entirely on the truth and delicacy of the level, and on its forming one body with the circle during each pair of observations so completely, that no motion can take place in the circle which is not instantly pointed out and measured by the level. In constructing an astronomical repeating circle, we should recommend the motion of the telescope and verniers to be made as light and delicate as possible, or what Troughton called a *flying* motion, while the motion of the circle in its collar should be rather heavy, so as scarcely to be disturbed, when unclamped, by moving the telescope. This is however in the original repeating circle not necessary, but only convenient.

In judging of the repeating principle as applied to any instrument, attention should be paid to the perfect independence of the telescope and level with respect to each other, and of their perfect connection with the circle when they are clamped to it. In some instruments a sort of repetition has been attempted by having the circle turn freely on the telescope axis, and clamping it alternately to the telescope and to a vernier circle which carries the level. It seems difficult in any such construction to secure the immoveability of the circle while clamping and unclamping is going on, and the construction has, we believe, gone out of use. There are some precautions which should be observed in every repeating circle, which we shall describe in reference to Borda's construction. Besides the perfect independence of the level, the telescope with its verniers and clamps should be perfectly self-balanced, so as not to apply any force to the clamp in any position; the telescope should be moved on the circle by two fingers pressing in opposite directions towards the extremities; the circle should be turned in its own plane by laying hold of the circle itself, and so gently that no jar can take place, or any springing back or forward of the telescope or its verniers from the moment of inertia: finally, the level must have time to settle before it is read off. When these precautions are duly observed, great accuracy may be obtained; in two instances, to our knowledge, where the latitude has been determined by unexperienced but intelligent observers, the results even of a single night have come within 1″ of the truth.

It may be worth mentioning that with the circle of Borda the measurements may be made by moving the telescope contrary to the order of divisions, &c. if the first observation is made with the face to the right hand instead of the left. There is no advantage in this modification, except perhaps that as the screws are handled a little differently, any discrepancy between an angle measured in the two ways would show an error in one or both the methods. It would be advisable, where several series are taken, to vary the direction in which the telescope is brought to its new position, and that in which the circle is turned upon the star. The tangent screw might be worked either constantly one way or the other, or alternately, but we should not expect any sensible difference in the results if the instrument is well made and the observers careful. If two steady observers can be found, the double altitude of any star may be repeated, with the genuine Borda and its two telescopes, exactly as a terrestrial angle, *i.e.* by measuring the angle between the star seen directly and by reflection from mercury. This would in theory appear to be the most perfect application of the instrument, as flexure has no effect upon the angle measured, being equal and in the same direction in both positions of the telescopes. The level is not wanted for this observation at all, but the circle must be set truly vertical. A single observer might indeed make the same observation with one telescope, as the level would show and measure any shifting of the circle. And here again the effect of flexure is eliminated from the observed double altitudes. Finally, double nadir distances may be observed of a star reflected from a mercurial horizon, exactly as double zenith distances are observed in the ordinary method. This last species of observation may have the advantage of being sometimes more convenient, but the chief reason why it is pointed out is, that the effect of flexure upon double nadir distances is equal, but in a contrary direction, to its effect on double zenith distances; the observer has thus an easy mode of ascertaining whether flexure exists and of measuring its amount and law.* We are not aware that any of the methods described in this paragraph have been put into practice.

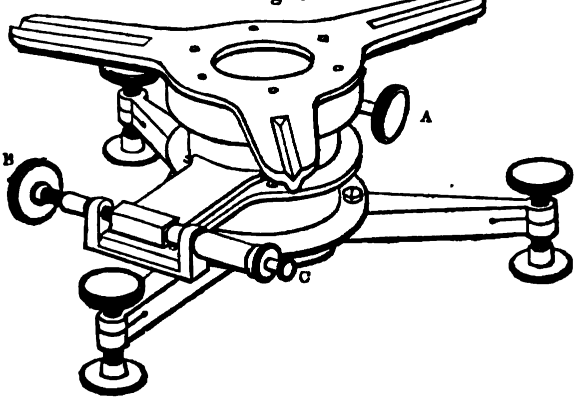
What precedes refers almost entirely to the repeating principle when applied to measurements in altitude. Instead of the circle of Borda and its two telescopes, later artists have given a motion in azimuth to their theodolites, in addition to the motion of the telescope and verniers, by which the angle can be measured precisely as in Mayer's original instrument. But in several instruments which we have seen there is a considerable probability of disturbing the circle clamp while moving the telescope or using its tangent screws. It is to secure the detection of any similar motion that a watch telescope, as it is called, is frequently added to English theodolites, and is indeed required for many, spoiled as they are by an unnecessary adjustment to zero, to save indolent or ignorant surveyors a simple subtraction. A watch telescope can scarcely be applied to a repeating theodolet, and we think that the repeating tripod may be so made as to be free from any objection. This was first constructed by Mr. Dollond on the suggestion of the late Astronomer Royal, and has been found very useful in the trigonometrical survey of Ireland.

The three foot-screws of an ordinary theodolet are placed in the three notches which are seen on the table of the tripod. This upper part turns heavily on a stout short centre, it is fixed by a clamp at A, and there is a tangent screw at B for giving slow motion. The steady action of the tangent screw is secured by a spring at C. It is

* We suppose that the apparent nadir distance of a reflected star is the same as the zenith distance of the star seen directly. The horizontal [illegible] of all the large circles which we have, vary in some manner with the altitude of the star observed, which seems contrary to what is here supposed. This [illegible] discrepancy is one of the most perplexing points in modern practical astronomy. The amount is however so small as scarcely to vitiate sensibly any conclusion drawn from reflected observations with so small an instrument as a repeating circle.

evident that if, in using an ordinary theodolet, R (the right hand object) is first bisected, the circle read off, and then L (the left hand object) is bisected, the circle being again

Fig. 3.



Repeating Stand by Messrs. Troughton and Simms.

read off, that the difference between the two readings is the angle to be measured, *if the instrument has not been shifted*, and if the bisection reading off, &c. are perfect. Now suppose the whole instrument to be taken up and set down exactly concentric with its first position, without any other alteration, but with the telescope on R; if L be a second time bisected, the difference between this latter and the preceding reading will be also the angle to be measured, and therefore the vernier will have passed over twice the angle, reckoning from the beginning. If instead of this impracticable taking up and setting down again, the stand on which the theodolet rests can be turned round concentrically with the theodolet, so that R is bisected by the telescope, the theodolet itself being untouched, it is clear that the operation is equivalent to that just described, and consequently that the telescope being brought on L by its own motion, the measure is obtained of twice the angle required, and the process may be continued *ad libitum*, until the errors of reading off and of division are eliminated. The only precaution to be observed is, that the stand must receive no angular motion from the motion of the telescope, and this is easily effected by giving a certain massiveness to the stand and a considerable heaviness to its motion while the telescope and its verniers revolve as lightly as possible. The observer should satisfy himself as to this perfect independence of the two motions and the stability of his repeating tripod by taking a set of twenty repetitions of an angle, always moving the telescope forward in the order of the divisions, and a second set of twenty of the same angle, carrying the telescope round the contrary way. The two results should agree if the stand has no motion; and if they do not, the upper motion must be lightened or the lower be loaded till they do agree. We should not feel satisfied to use the repeating stand if a motion of the telescope a little ruder than necessary affected its position although unclamped; and the stand which is here figured fulfilled this condition very well with a 12-inch theodolet. As the absolute coincidence of the axes of the tripod and theodolet cannot be obtained, the angle should be repeated at least once round the circle, and, if the case requires it, until the multiple angle is very nearly equal to one, two, or more circumferences. The original repeating tripod as designed by Mr. Pond was considerably higher than that figured here. (See Pearson's *Practical Astronomy*, plate xxix., fig. 7, and vol. ii., p. 513.) A little greater nicety is thus given to the adjustment of the vertical axis of the tripod, which is not necessary, and the snugness of the present stand is, we think, more than an equivalent. The axis of the tripod must first be set vertical, either by a level of its own or the theodolet level, exactly as is described in the adjustment of the vertical column of Borda's circle. For the subsequent adjustments, &c. of the theodolet, see THEODOLET.

The best account of the repeating circle in English will be found in Troughton's article 'Circle,' Brewster's *Cyclopædia*, and in a paper by the same author, *Memoirs Astron. Soc.*, vol. i., p. 33, which is unfavourable to the repeating principle. (See too Pearson's *Practical Astronomy*, vol. ii., p. 488 et seq.) We do not agree with all Mr. Troughton's objections: some apply only to the defective construction of Borda; and others may be either got over by skilful handling, or belong to all small instruments. It must be remembered in reading his papers, that too much was then expected from this instrument, and that its proper sphere of action was absurdly extended. We doubt whether as good latitudes have been got with any small circles as with repeating circles, and it is to this purpose, we think, that they should be confined.

REPETEND, the part of a CIRCULATING DECIMAL which is perpetually repeated. The word however means simply *to be repeated*, and is so little used in the above sense, that it might be advantageously employed with more generality.

REPLEVIN (*delivrance de namps, replegiatio*). In the middle ages the performance of legal duties was enforced by taking the person, the lands, or the goods of the defaulter into the custody of the party authorised to enforce the performance of such duties. When such a taking was effected, the party was said to be distrained (*districtus*, put under compulsion), by his body, his lands, or his goods, to do the act in respect of which he was supposed to have made default. [DISTRESS.]

Upon a distress being effected, the body, land, or goods, as the case might be, of the distrainee remained in the custody of the distrainor until the act for which the enforcing of the distress had been made was performed: unless the distrainee brought the question of the legality of the taking before a competent tribunal, in which case he might either await the result of his legal proceedings, or, if he was desirous of obtaining a more speedy liberation of the thing distrained, he might replevy it by giving a pledge or security for a replacing it in the custody of the distrainor in the event of the legal decision being in favour of the latter.

The alleged defaulter might contest the legality of the taking in an action of trespass. [TRESPASS.] But in this form of action he could recover damages only. He would not be entitled to the liberation of his body, lands, or goods, as the case might be, pending the suit; nor indeed when the suit had terminated in his favour, could he by any proceeding which could be resorted to in the action of trespass be relieved from the distress. The remedy by which a party was to recover his liberty or the property distrained, and also damages for the temporary detention, was an action of replevin. Where the person of the plaintiff was taken, his remedy was by an action of replevin in a peculiar form, which, taking its denomination from the writ by which it was commenced, was called de homine replegiando. This proceeding was however surrounded by so many difficulties, rendered perhaps indispensable by the necessity of preventing criminals from using it as a means of evading justice, that it has now become obsolete in England, parties entitled to redress by the writ of homine replegiando preferring to obtain their discharge by the more speedy and summary process of habeas corpus, or, as it was formerly called, a writ of corpus cum causâ. [HABEAS CORPUS.] The great mass of the cases of homine replegiando in the old law books arose upon the seizure and detention of persons whom the parties seizing claimed as their fugitive villeins [VILLEIN]; and this process was frequently resorted to in Jamaica and other slave colonies. The seizing of the lands of a defaulter by way of distress has long ceased to be practised.

Formerly not only lands but incorporeal hereditaments were the subjects of replevin, of which a remarkable instance occurred in the reign of Edward III. (*Parliament Rolls*, vol. i., 45.)

The third form of replevin, and the only one now in use, is replevin of goods, called in the old statutes replegiari de averiis, cattle (in law Latin, averia) being the species of goods which usually formed the subject of a distress.

If the goods of a party were taken out of his possession against his will, he was entitled at common law to sue out a writ of replegiari facias, by which the sheriff of the county in which the goods were taken, or of the county in which they were detained, was required to cause the goods to be replevied, *i.e.* restored to the owner upon his giving pledges for the prosecution of his action, and also by statute pledges for the return of the goods to the distrainor in case a return should be adjudged. As the right of the party from whom the goods are taken to have the possession restored to him by replevin, depends upon the property belonging to him—if the taker of the goods claim them as his own property, the power of the sheriff is suspended, until the party has sued out a writ de proprietate probandâ, by which the sheriff is directed to summon a jury for the purpose of trying whether the goods are the property of the plaintiff or of the defendant; and if they are found to be the property of the plaintiff, then to replevy them; if of the defendant, the plaintiff's claim to be restored to the possession of the goods remains in suspense until the termination of the action. A special action lies at the suit of the crown and the party aggrieved, for falsely claiming property in the goods distrained, and thereby preventing a replevin.

A replevin does not lie for goods taken in execution, or for goods seized for a debt to the crown. In a very intemperate speech, addressed by Hyde, afterwards Lord Clarendon, to the House of Lords, upon a charge against the barons of the exchequer, for enjoining the sheriffs of London not to execute a writ of replevin for goods seized by the officers of the custom-house for refusing to pay the subsidies of tonnage and poundage, he is stated to have said, in the course of his argument, 'We all know a replevin lies against the king, if the goods be (be not?) in his own hands.' (Rushworth, part 3, vol. ii., 1361.) Though this strange assertion has been regularly transcribed by succeeding writers, it appears to be altogether unfounded. The replevins sued out for goods seized in respect of tonnage and poundage would issue against the officers as for goods seized by them in respect of debts claimed to be due to the crown. But goods seized for the king's debts cannot be replevied without the special mandate of the king or of the barons of the Exchequer. Still less could replevin be brought in respect of goods in the actual possession of the king, and upon an allegation of their having been wrongfully taken by him.

Replevin does not lie for goods taken in a foreign country, though afterwards imported here.

If upon a distress taken by the superior landlord upon premises in the possession of an under-tenant, the mesne or intermediate tenant puts his cattle in the place of those distrained, as by law he was allowed to do, he might replevy the goods so substituted, though the latter were never distrained.

Replevin lies notwithstanding an express agreement that the landlord shall be at liberty to distrain and hold the goods against pledges (that is, notwithstanding a tender of pledges) until the rent be paid; for goods cannot be made irrepleviable by the mere agreement of the parties.

Executors may maintain replevin for the goods of the testator taken in his lifetime, and a husband may bring replevin alone without naming his wife, for the goods of the wife taken before the marriage; as the property in the goods passes to the executors, and to the husband respectively, notwithstanding the seizure and detention.

A person may in some cases support a replevin without being the owner of the goods, as where the plaintiff is the bailee of the goods taken. [Bailment; Pledge.]

The writ of replegiari facias did not, as in the case of most other writs, confer upon the sheriff a bare ministerial authority: it operated as a commission clothing the sheriff with authority to determine the legality of the distress in the county court, in which he presides judicially. Notwithstanding the facility thus afforded, the remedy by writ of replegiari facias, which must be sued out of the Court of Chancery, was attended with great inconvenience and delay at a period when the chancery followed the person of the king, and many weeks might elapse before the party could obtain the restoration of his property. There existed also other difficulties connected with the execution of this writ. The inconvenience was felt as early as the time of Henry III., in whose reign it was provided by the statute of Marlbridge, passed in 1267, that if the cattle of any person be unjustly taken and detained, the sheriff, after complaint made to him thereof, may deliver them without hindrance or refusal of him who took the cattle. In 1555, with a view of making the delivery of distresses more expeditious, it was enacted by 1 and 2 Philip and Mary, c. 12, s. 3, 'that every sheriff of shires, being no cities nor towns made shires, shall at his first county-day, or within two months next after he hath received his patent of his office of sheriffwick, depute, appoint, and proclaim in the shire-town within his bailiwick, four deputies at the least, dwelling not above twelve miles distant from one another; which deputies so appointed and proclaimed shall have authority in the sheriff's name to make replevies and deliverance of such distresses, in such manner and form as the sheriff may and ought to do.' The proceeding by writ of replevin does not seem to be affected by the Uniformity of Process Act (2 Will. IV., c. 39, s. 11), which directs that the writs mentioned in that Act shall be the only writs for the commencement of personal actions in the cases to which such writs are applicable, inasmuch as none of these writs are capable of being applied to the objects to be accomplished by the writ of replevin.

The proceeding by plaint under the statute of Marlbridge, 52 Henry III., c. 21, has practically long superseded the proceedings by writ of replegiari facias. In numerous inferior courts jurisdiction is possessed, under charters from the crown, to hold pleas of replevin by plaint. By an act passed in 1285 (Westm. 2, c. 2), the sheriff is required, before he make deliverance of the distress, to take from the plaintiff pledges not only for the prosecution of the suit, but also for returning the cattle in the event of a return being adjudged. This statute is silent as to the amount in which security should be taken. For the purpose of fixing the extent of the responsibility of the pledges and of preventing vexatious replevins in cases of distress for rent, it was enacted in 1737 (by 11 Geo. II., c. 19, s. 23), that sheriffs and other officers having authority to grant replevin shall in every replevin of a distress for rent, take, in their own names, and before any deliverance is made of the distress, from the plaintiff and two responsible persons as sureties, a bond in double the value of the goods distrained (such value to be ascertained by the oath of one or more credible witness or witnesses not interested in the goods or distress, such oath to be administered by the person granting such replevin), with a condition for prosecuting the suit with effect and without delay, and for duly returning the goods and chattels distrained in case of a return being awarded.

By this latter statute the sheriff or other officer granting the replevin is authorised to assign the replevin bond to the avowant (the party who took the distress in his own right), or to the person making cognizance (the party acknowledging the taking of the distress on behalf of some other person, and as his bailiff, for the term applied to any person undertaking this species of agency, the duty of taking distresses having been formerly part of the ordinary duties of the bailiffs of manors); and the assignee of the bond is thereby empowered to sue upon it in the superior courts, in the event of the condition of the bond not being performed.

Although the county court has jurisdiction over the matters in dispute in actions of replevin, whether the proceeding be by writ or by plaint, the usual course, after security has been taken and the property returned, is to remove the proceedings into the Court of Common Pleas. This is commonly effected by a writ of recordari facias loquelam, called familiarly by practitioners a re. fa. lo., whereby the sheriff is commanded that he cause the plaint to be recorded which is in his county court between A and B, of the cattle, goods, and chattels of A, said to be taken and unjustly detained, and that he have that record before the justices at Westminster under his seal and the seal of four knights of the county, of such as shall be present at the said recording, and that he give a day to the parties to be in court. This proceeding is evidently borrowed from the Norman practice of requiring the presence of four knights to constitute a record in certain cases, though in other cases other persons might be recordeurs [Recorder], the supreme recordeur being the duke of Normandy himself (Grand Coustumier), all whose courts therefore, whether in Normandy or in England, in which he was supposed to be present, were courts of record. If the plaint which was required to be removed was not in the county court, but in the court of the lord of a franchise, the writ directed the sheriff to go to the lord's court, taking with him four knights, and there to cause the plaint to be recorded. This particular form of re. fa. lo. is called an accedas ad curiam. In some cases, proceedings in replevin may be removed from the county court into the Common Pleas by writ of pone loquelam; and where such proceedings are depending in an inferior court of record, they may be removed into any of the three superior courts by writ of certiorari.

Upon the appearance of the parties in the Court of Common Pleas (or the removal may be into the Queen's Bench, and, if from an inferior court of record, into the Exchequer also), the plaintiff declares against the defendant for the taking of the goods and chattels of the plaintiff, at such a time and in such a place, and unjustly detaining them against sureties and pledges (that is, notwithstanding the plaintiff had offered security to perform the act required, in case it should be found that he was liable so to do), until they were replevied. This is the ordinary form, and it is called declaring in the detinuit. But if the goods have not been restored to the plaintiff, the declaration charges that he still detains them. This is called declaring in the detinet, in which the plaintiff claims damages large enough to cover the whole value of the goods taken from him; whereas in replevin in the detinuit, the damages recoverable are for the taking and for the short detention, until the replevying, which, as the goods may be replevied immediately, are merely nominal, and a small amount to cover the expense of the replevin bond.

The declaration being delivered, and a rule to plead being given, and a demand of plea made, the defendant either confesses the action, or suffers judgment by default, or pleads or demurs to the declaration. In the first case, final judgment is entered for the sum confessed. In the second case, interlocutory judgment is signed, and a writ of inquiry issues to assess the amount of the damages which the plaintiff has sustained by reason of the taking and detaining of his property. If the goods have been restored to the plaintiff, the damages will be measured by the inconvenience and the expense incurred in getting them back; if, as is seldom the case, they have not been restored, the amount of damages will include the value of the goods at the time of their being taken.

Thirdly, the defendant may plead or demur to the declaration. In replevin there is no general issue, properly so called, that is, a plea which puts the plaintiff upon proof of all the material allegations in the declaration. If the defendant plead non cepit, he admits that the goods belong to the plaintiff, and denies the taking only. If he plead that the goods do not belong to the plaintiff, he admits that he took and detained them. The allegation that the defendant detained the goods against sureties and pledges, is considered as a mere form, and not traversable. Therefore, although the action of replevin was given for the purpose of trying the validity of distresses, yet as no proof of any tender of security for the performance of a duty distrained for can be required from the plaintiff, the action of replevin may, in effect, be maintained upon any species of wrongful taking; and in Ireland this form of action is not unfrequently resorted to as a mode of trying a disputed right of property in goods. But where the taking was not wrongful, an action of replevin does not lie, as where the defendant acquired the possession by delivery from the plaintiff, although the possession has been wrongfully continued, for which injury the proper remedy is an action of detinue (Com., *Dig.*, 'Replevin,' A.); though even in the case of a bailment (consignor against consignee), Lord Redesdale, then chancellor of Ireland, refused to quash a writ of replevin.

In ordinary cases, the defendant avows in his own right, or makes cognizance, as bailiff to his employer, for rent, or for some other duty or cause, for which a distress is allowed by law [Distress], in doing which he may set up any ground of distress, though differing from that expressed at the time when the distress was made.

The plaintiff may reply to the defendant's plea as in other cases [Pleading]; but inasmuch as an avowant, or a person making cognizance, is not merely a defendant, but a party seeking to recover something, the plaintiff's answer to an avowry or cognizance, which is in the nature of a declaration for the right or duty withheld, is called a plea in bar to such avowry or cognizance; the defendant's answer to which plea or bar is called a replication.

The pleadings in replevin vary according to the nature of the claim which formed the subject of the distress, and the circumstances under which the plaintiff is enabled to meet such claim. (Com., *Dig.*, 'Plead.,' (3 K); Selw., *N. P.*, 'Replevin;' Wilkinson *On Replevin.*)

If upon issue joined, a verdict is found for the plaintiff, the jury usually assess the damages; but if they omit to do so, a writ of inquiry issues to assess damages for the taking and detention, and also for the value of the goods, if it appear either by the pleading or by a suggestion by the plaintiff on the roll that the goods have perished or are still detained. But when the taking was lawful, and the detention only wrongful, no damages are given for the taking, as where goods are distrained damage feasant (wrongfully encumbering the defendant's property) and are impounded after tender of sufficient amends. Upon a judgment for the plaintiff on demurrer, a writ of inquiry issues to assess the damages, framed, as in other cases, with reference to the state of the record. Where there is judgment for the defendant upon verdict or demurrer, or the plaintiff is nonsuited, the judgment directs that the defendant shall have the goods restored to him without being again subject to being replevied, which is called a return irreplevisable; and by 17 Car. II., c. 7, on distress for rent, if the plaintiff in replevin by plaint, or writ depending in any court at Westminster, be nonsuited before issue joined, the defendant making a suggestion in nature of an avowry or cognizance for such rent, the court is directed, upon his prayer, to award a writ to inquire what rent is in arrear, and the value of the goods and cattle distrained; and on the return of the inquisition the defendant is to have judgment to recover the arrears of rent, if the goods, &c. distrained amount to that value, otherwise to the value of the distress, with full costs; and if the plaintiff be nonsuited after avowry or cognizance, and issue joined, or a verdict be for the defendant, the jury are to inquire the amount of rent in arrear, and the value of the distress; and if judgment be for the defendant on demurrer, the court is to award a writ to inquire the value of the distress, and the defendant is to have judgment for the arrears mentioned in the avowry or cognizance, if the distress amount to so much, otherwise to the value of the distress, and his costs.

If upon a replevin, either by writ or plaint, or upon a writ of retorno habendo after judgment, the sheriff returns that the cattle, &c. are driven away (eloigned, elongata) so that he cannot replevy them, a writ may issue commanding the sheriff to make reprisals by taking the cattle, &c. of the distrainor, and to detain them until he is able to replevy the cattle, &c. of the distrainee. This process, which is now nearly obsolete, was called a capias in withernam, or a capias by way of counter-taking, from *wither* (against; in German, *wider*) and *nam*, a taking or distress. A special action of trespass also lies for removing a distress so that it cannot be replevied. This latter offence was formerly called a 'vee,' or 'vetitum namium,' by which term is to be understood, not, as might be supposed, a forbidden distress, but a distress forbidden or refused to be replevied.' (2 *Inst.*, 140.)

If after goods have been replevied, and before the suit has been decided, the defendant makes another distress for the same cause, such second distress is called a recaption, and the course is to sue out a special writ for the restoration of the goods and for the punishment of the recaptor; since, whether the first taking was right or wrong, the defendant is not justified in thus anticipating the judgment of the court. It is not material whether the second taking be of the same goods or of other goods, provided they belong to the same party, and are taken for the same cause: but if the landlord distrain the goods of A, who replevies, and afterwards, finding the goods of B upon the land, he distrains them for the same rent, no writ of recaption lies. B can only replevy or bring an action of trespass or trover.

At common law, if the plaintiff was nonsuited, although the defendant became entitled to a return of the goods, yet the judgment was not that the return should be irreplevisable, as in a judgment upon a verdict where the right has been tried. The plaintiff might have again sued out a replevin, and so after several successive nonsuits. To put an end to this vexatious proceeding, the statute of Westm. II., c. 2, gave the plaintiff a writ of second deliverance instead of a new replevin, in which, if the plaintiff in any manner fail in his suit, the defendant will have judgment for a return irreplevisable. In other respects the proceedings in the action of second deliverance are similar to those in the action of replevin.

REPLICATION. [Pleading.]

REPORTING. [Newspapers, p. 195.]

REPORTS (in Law) are relations of the proceedings of courts of justice. They contain a statement of the pleadings, the facts, the arguments of counsel, and the judgment of the court in each case reported. The object of them is to establish the law, and prevent conflicting decisions, by preserving and publishing the judgment of the court, and the grounds upon which it decided the question of law arising in the case. The records themselves are not easily accessible to the public, and they contain only the decision itself.

The earliest reports extant are the 'Year-books.' It is said that some few exist in MS. of the reign of Edward I., and a few broken notes are to be found in Fitzherbert's abridgment. A series of these commences, and are printed, from the reign of Edward II. They were published annually, which explains their name, from the notes of persons, four in number, according to Lord Coke, who were paid a stipend by the crown for the purpose of committing to writing the proceedings of the courts. These early a.

counts of cases are very short, abrupt, and often confused, especially from the circumstance that it is frequently difficult to ascertain whether a judge or a counsel is speaking. At that time judges were dismissed at the pleasure of the crown, and after their dismissal returned to their previous position of counsel.

The Year-books continue, with occasional interruptions in their series, down to the reign of Henry VIII. The omission during the time of Richard II. has been attempted to be supplied by Bellewe, who collected and arranged the cases of that period which had been preserved by other writers. The Year-books are wholly written in Norman-French, although by the 36 Edw. III., stat. 1, c. 15, it was enacted that all pleadings should be in the English language, and the entries on the rolls in Latin. The Norman-French continued to be used by some reporters even as late as the eighteenth century. The last which appeared in that tongue were those of Levinz and Lutwyche; the former in 1702, the latter, in French and Latin, in 1704. The Year-books of later date have more continuity of style and fullness of discussion: cases are cited, and the decision of the court is given at greater length, with more solemnity and clearness. About the end of the reign of Henry VII. it is probable that the stipend was withdrawn. Only five Year-books exist for the ensuing reign, and none were published after it. Lord Coke observes, you may see no small difference between the cases reported in the reign of Henry VIII. and those previous. Their place was shortly afterwards supplied by reports compiled and published by private individuals on their own responsibility, but subject for some time to the inspection and approbation of the judges, whose testimony to the ability and fitness of the reporter is often prefixed to the Reports. This however soon became a mere form, as appears by the statement of Lord-Keeper North, who speaks slightingly of the Reports in his time as compared with his favourite Year-books.

North had such a relish for the old Year-books that he carried one in his coach to divert his time in travel, and said he chose it before any comedy. He thought the Year-books of Henry VII. the best for the student to begin with, as the law then became more settled; and was of opinion that they were better than the recent Reports, as 'compiled by men solemnly authorised, and not as now, when every ordinary practiser publisheth his Reports as he pleaseth, and the bookseller procureth an imprimatur.—And thus the shelves are loaded with Reports.' (Roger North's *Life of Lord-Keeper North*, vol. i., pp. 27, 28.)

During the reign of Henry VIII. and his three successors, Dyer, afterwards chief-justice of the Common Pleas, took notes as a reporter. Benloe and Dalison were also reporters in those reigns. In the time of Elizabeth many eminent lawyers reported the proceedings of the courts, and, from the ability with which they acquitted themselves, added to the previously unsettled state of the law, the Reports of about this period have acquired very great authority. Anderson, Moore, Leonard, Owen, Coke, and Croke all lived about this time. But the first printed accounts of cases published by a private hand are those of Edmund Plowden, the first part of which appeared in the year 1571, under the title of 'Commentaries.' [PLOWDEN.] A few years afterwards the executors of Dyer published the notes of their testator under the express name of 'Reports,' being the first published under that title. These were followed, in 1601 and 1602, by those of Sir Edward Coke, which, from their excellence, have ever been dignified by the name of 'The Reports.' During this time reporters did not, as they have done in more modern times, confine themselves to one court. In the same volume are found reports of cases in chancery, in the three superior courts, the court of wards, &c. During the reign of James I., Lord Bacon and Sir Julius Cæsar suggested to the king the appointment of two officers for the purpose of taking notes and minutes of proceedings in the courts. James acceded to the suggestion, and a copy of his ordinance for their appointment, at a salary of 100*l.* each, is still extant. (Rymer's *Fœdera*, 15 Jac. I., 1617.) The ordinance does not however appear to have been acted upon, and Reports continued to be compiled and published by private hands only.

The English language was first used by reporters about the time of Elizabeth. Lord Coke employed it in his 'Commentary upon Littleton.' In his preface he states why he thought it convenient to do so; and adds that his conduct was not without precedent. From the period of Elizabeth down to the present, reports have been published of the proceedings in all the courts. During most of the time contemporaneous reports exist of the same cases, though frequently given under different names. Coke, in his day, thought the following distich applicable:—

'Quæritur ut crescunt tot magna volumina legis;
In promptu causa est, crescit in orbe dolus.'

This is curious as evidencing the number and fecundity of reporters at that time. North also complains of the great number of Reports.

(Coke's *Reports*, Preface to part 11; Dugdale's *Origines Juridiciales*; Reeves's *History of the English Law*.)

REPRIEVE (from the French *repris*, withdrawn), in criminal law, means the withdrawal of a prisoner from the execution and proceeding of the law for a certain time. Every court which has power to award execution, has also power, either before or after judgment, to grant a reprieve. The consequence of a reprieve is, that the delivery or the execution of the sentence of the court is suspended. A reprieve may proceed from the mere pleasure of the crown expressed to the court, or from the discretion of the court itself. The justices of gaol delivery may either grant or take off a reprieve, although their session be finished, and their commission expired. A reprieve proceeding from the discretion of the court is usually granted when, from any circumstance, doubt exists as to the propriety of carrying a sentence into execution. This doubt may be created either from the unsatisfactory character of the verdict, the suspicious nature of the evidence, the insufficiency of the indictment, &c., or from the appearance of circumstances favourable to the prisoner. When a reprieve has been granted with a view to recommend to mercy a prisoner capitally condemned, a memorial to that effect is forwarded to the secretary of state, who recommends the prisoner to the mercy of the crown, and to a pardon, on condition of transportation or some lighter punishment. Where it has been granted by reason of some doubts in point of law as to the propriety of the conviction, the execution of the sentence is suspended until the opinion of the judges has been taken upon it. The sentence is then executed or commuted in accordance with their opinion.

There are two cases in which a reprieve is necessarily granted. One is where a woman who has been capitally convicted pleads her pregnancy in delay of execution. Where such a plea is made, the judge must direct a jury of matrons to inquire of the fact; and if they find that she is quick with child, the execution is delayed, either till after her delivery, or proof by lapse of time that she was not pregnant. The other is where a prisoner appears to have become insane between judgment and the award of execution. In such case a jury must be sworn to inquire whether he really is insane. If they find that he is, a reprieve must be granted. (*Termes de la Ley*, 498; Hale, *P. C.*; 2 Hawk., *P. C.*, book ii., c. 51, s. 8, 9; 4 Bl. *Com.*)

In practice a reprieve is thus granted:—Before leaving an assize town, a calendar containing the names, offences, and sentences of the prisoners is prepared by the clerk of assize, and is signed by the judge. If he thinks proper to reprieve any one of them, he writes the word 'reprieved' in the margin of the calendar, opposite to the name of the prisoner, as follows:—

'*Reprieved.*	A. B. *for* the murder of C. D.	To be hanged.'

If he leaves A. B. for execution, and subsequently reprieves him, he writes to the under-sheriff and the gaoler to say so, and such letter from the judge stays execution.

If the reprieve is sent by the secretary of state, it is under the sign manual of the king.

REPTILES. *Reptilia.* The word reptile, in its general sense, signifies any creature that creeps upon the ground; but when used zoologically, it is confined to the designation of those quadruped, biped, and apod oviparous and ovoviviparous vertebrated animals that breathe by means of lungs principally, and are without hair, feathers, or mammæ. Such animals form the subject of that branch of zoological science termed *Herpetology*.

In mammalogy and ornithology we find that the animals which are treated of under those branches are respectively formed according to one leading type, which, however modified, may be traced throughout the whole chain of beings with which those branches of zoology are conversant. From an elephant to a mouse, from a whale to a porpoise, the same uniform principle of construction may be recognised. The same principle of organization governs the conformation of an ostrich and a humming-bird. But in herpetology we have various types or principles of structure. Not to dwell upon the more obvious differences in the organization of a tortoise and a common snake, we shall find in more cognate creatures, the Saurians for example, a striking variation in structure. The skeleton of a crocodile differs widely from that of a chameleon, as a glance at the figures given in this work of the osseous parts of each will show; and how widely are these again separated from the frogs and toads.

But before we proceed to inquire into the more remarkable differences of structure observable in reptiles, it will be necessary to observe what animals have been included in that class by zoologists.

The antient monuments of the Egyptians prove that the great groups of the tortoises, the lizards, the serpents, and the frogs, as well as their habits, were well known to that people; and the Sacred Scriptures abound in passages (the Old Testameut especially) showing that a similar knowledge obtained when they were written. Indeed from the earliest times these forms must have attracted the attention of man; and a natural desire on his part to ascertain which of them were dangerous, and which were innocuous, must have led him to particular inquiry in order to solve the doubt.

In Herodotus and Athenæus, there are not wanting passages indicative of precise notions respecting many species of reptiles.

That this class of animals had employed no small portion of the acute observation of Aristotle, and that he was well acquainted with their form, structure, and habit appears from the great work which has justly immortalised him as a zoologist. We need only refer to the following passages in his 'History of Animals' to be well satisfied of the fact (lib. i., c. 1; lib. ii., c. 10, 17; lib. v., c. 3, 4; lib. viii., c. 2, 17). We find noticed the oviparous quadrupeds, viz. the land and marine *Testudinata*, the crocodiles, the lizards, &c.; the serpents, with an observation that they may be placed at the side of the lizards, as resembling them closely, if we suppose the lizards to be lengthened and deprived of their feet. The frogs are also often mentioned. Aristotle was quite aware of the generation of most of this class; he knew that the viper was ovoviviparous, and states that it brings forth its young alive, having produced an egg internally (*ὁ μὲν ἔχις ἔξω ζωοτοκεῖ ἐν αυτῷ πρῶτον ᾠοτόκησας*); and he indicates what animals should be designated as *amphibia*.

Pliny writes much and elegantly concerning this class; but the best of his observations are borrowed from Aristotle, and his far from well-digested compilation is mixed up with so great a portion of error and so large a measure of credulity, as justly to merit the censure passed by Cuvier on this voluminous and pleasant author, but too often fabulous natural historian.

Darkness settles on the period from the fourth to the ninth century as far as the history of the sciences is concerned; but at that epoch the best Greek works were translated by the Arabs, who thus handed on the most curious known facts, especially those which had any reference to the art of medicine. Again there is a great void till the early part of the sixteenth century, when France produced Belon and Rondeletius, Italy Salviani, and Switzerland that prodigy of erudition, as he is designated by Boerhaave, Conrad Gesner. Two of Gesner's books are devoted to the natural history of reptiles—lib. ii., *De Quadrupedibus oviparis*, and lib. v., *De Serpentium Naturâ*. These treatises are not mere catalogues with cuts; they are learned and elaborate dissertations, in which the antient and modern nomenclature of the object treated of, its form, its geographical position, its manners, its habits, its anatomy, its economical and medical uses, and its mythological history are discussed.

Towards the end of the same century, Aldrovandi appeared. The results of fifty years research in collecting objects of natural history, the drawings which he caused to be made of them, and his diligent studies relative to every point bearing on their history, appeared after his death, which happened in 1605, in fourteen volumes folio. The two books upon serpents and lizards do not appear to have been published till 1640, when they were given to the world by Professor Ambrosini of Bologna: twenty-two chapters are occupied by the serpents, and six only are dedicated to basilisks, dragons, and other lizards, the greater part of which however are fabulous.

Jonston's *Historia Naturalis*, edited by Henry Ruysch, son of the celebrated anatomist, under the title of *Theatrum universale omnium Animalium*,* is principally a selection of the remarks of those who preceded him, and he has but few observations which can be called his own, still fewer indeed than Aldrovandus, who does not abound in originality. The fourth book treats of digitated oviparous quadrupeds, and there are two books on the serpents; but if little can be said of his originality, he certainly deserves praise for the attempt at systematic arrangement which his work exhibits, and which has the merit of exactness. His chapters, in point of fact, form a methodical table. Thus we have a treatise on frogs, toads, and tree-frogs; on the lizards, on the tortoises; and on the serpents.

But it is to our countryman John Ray that we owe the first arrangement which can be truly called systematic: in his *Synopsis methodica Animalium Quadrupedum et Serpentini generis*, which first appeared in 1693, we have a classification based on the mode of respiration, the volume of the eggs, their colour, &c. This basis is not indeed strengthened by any description of the habits or organization of the reptiles on which he treats, and cannot but be considered as insufficient; still it is valuable, and has the merit of leading the way to more accurate methods.

The *Amphibia* form, in the last edition of the *Systema Naturæ*, published by Linnæus himself, the third class of the animal kingdom. This class consists of three orders:—

1. *Reptiles*, which are described as *pedati, spirantes ore*.
2. *Serpentes*, which are characterised as *apodes, spirantes ore*.
3. *Nantes*, which are characterised as *pinnati: spirantes etiam branchiis lateralibus*.

The last order, which consists of cartilaginous and other fishes, forms no part of our present inquiry, which is confined to animals included in the two first.

The *Reptiles* are thus designated:—*Os respirans pulmonibus. Pedes quatuor*:—and they consist of the genera *Testudo* (Land, Marine, and Freshwater Tortoises); *Rana* (Frogs and Toads); *Draco* [DRAGON]; and *Lacerta*, which includes the Crocodiles and the rest of the Saurians.

The *Serpentes* have the following general character:—*Os respirans tantum pulmonibus. Pedes nulli, pinnæve natatoriæ nullæ. Aures nullæ*: and they comprise the following genera:—*Crotalus* (the Rattle-Snakes); *Boa* (Boas and Pythons); *Coluber*, including all serpents which have abdominal scuta and subcaudal scales, whether poisonous or not; *Anguis*, including the Slow-worms, *Bipes* and other serpents, the poisonous *Cerastes*, &c.; *Amphisbæna*; and *Cæcilia*.

The work on oviparous quadrupeds, published by Klein in 1751—*Quadrupedum dispositio brevisque Historia Naturalis*—requires hardly any notice, and another which made its appearance in 1755—*Tentamen Herpetologiæ*—deserves as little. The latter, notwithstanding its extensive title, treats only of serpents; and the value of the criticisms of this opponent—he cannot be called rival—of Linnæus may be appreciated by his arranging in the same category the Earthworms, Tapeworms, and Leeches.

But it is to the *Specimen Medicum*† presented by Laurenti at Vienna, in order to obtain the degree of Doctor, that we must look for the first well-digested history of reptiles. This remarkable work, which omits the Tortoises, but, in other respects may be said to have formed an æra in the science of Herpetology, is divided into two parts: the first relates entirely to the natural history and characters of the genera, the second is devoted to specific descriptions, and the record of experiments made to detect the existence of poison in some species, and the effect of remedies in certain cases. But though this most able treatise is always quoted as that of Laurenti, it has been attributed to Winterl, a distinguished chemist of Vienna, whose name appears only in the last page of the work as having been the assistant of Laurenti—or rather his *collaborateur*—in his therapeutic experiments.

The author or authors of this valuable book assign the following characters to the class of *Reptiles*, which are described as cold animals, without hairs or mammæ, furnished with lungs, which act without a diaphragm, and generally without ribs, the functions of which are performed by the

* This is the most esteemed edition, and was published in 1718, in two vols. fol. Jouston's 'Thaumatographia Naturalis in decem classes distincta' appeared at Amsterdam in 1632. There are several editions of the 'Historia Naturalis.' That of Amsterdam (1657) is in one vol. folio.

† 'Exhibens synopsin Reptilium, emendatum cum experimentis circa venena et antidota Reptilium Austriacorum,' Viennæ, 1768, 8vo.

throat in first drawing in the air and then driving it into the lung; as hybernating for a very long period, not masticating their prey, but swallowing it entire, and digesting it very slowly; as capable of long fasts (often for half the year), et copulâ diu coherentia; as renewing their youth, as it were, by casting their skins; and as objects of suspicion to man, and indeed all other mammiferous animals.

The Tortoises, as we have seen, are not comprised in the work which bears the name of Laurenti. The reptiles there treated of are separated into three orders, viz. *Salientia*, *Gradientia*, and *Serpentia*.

The *Salientia* consist of the Toads and Frogs; the *Proteus* of Laurenti, which appears under this order, being the larva of the *Rana paradoxa*. The reptiles under the order *Salientia* are characterised as having the posterior feet proper for leaping, the body without scales, the epidermis mucous, the ears hidden by a membrane, neither teeth nor nails (excepting the *Pipa*),* no sexual organs reaching beyond the *cloaca*, and the loss of the tail as a consequence of the metamorphosis. For the genera the reader is referred to FROGS [vol. x., p. 494].

The characters of the second order, *Gradientia*, are the possession of four feet proper for walking, which cannot operate without the elevation of the abdomen from the ground, and a distinct neck and tail. The genera consist of the *Protei*, forming the 5th genus; 6th, the Tritons, or Aquatic Salamanders; 7th, the Terrestrial Salamanders; 8th, *Caudiverbera*, corresponding to the *Uroplates* of Duméril and Bibron; 9th, the Geckos; 10th, the Chameleons; 11th, the Iguanas; 12th, the Basilisks; 13th, the Dragons; 14th, the *Cordyli*, which correspond to the *Agamæ*; 15th, the Crocodiles; 16th, the Scincks; 17th, the *Stelliones*; and 18th, *Seps*, which last conducts us to

The third order, *Serpentia*, which are defined as having a rounded body, in which neck and tail are confounded, a repent progression, dilatable jaws, not solidly articulated, a very extensible œsophagus for the reception and deglutition of a disproportioned prey; and genital organs opposed and placed on the margins of the *cloaca*. The genera are 19th, the *Chalcides*; 20th, the *Cæciliæ*; 21st, the *Amphisbænæ*; 22nd, the *Orvets* (*Anguis*); 23rd *Natrix*; 24th, the *Cerastes*; 25th, the *Coronelles*; 26th, the *Boæ*; 27th, *Dipsas*; 28th, *Naja*; 29th, the Rattlesnakes (*Caudisona*); 30th, *Coluber*; 31st, the Vipers; 32nd, the Cobras; 33rd, the Asps; 34th, the Constrictors; and 35th, the Flat-tailed Serpents (*Laticauda*).

Though there is room for criticism with regard to the distribution of parts of this arrangement and the omission of that great and interesting class of reptiles the *Testudinata*, no zoologist will deny the lucid and natural views of the author, nor accept the *specimen* as any other than a most valuable advancement of herpetological science.

It will be seen that we have omitted the great work of Roesel on Frogs, which being limited to that particular race, is noticed in the article which bears their name. [FROGS.]

Though Scopoli devoted but a few pages to the Reptiles, his observations must not be passed by. The pupil of Linnæus, he showed himself worthy of his master: but at the same time he appears in his arrangement to have been fettered by the principles adopted by the great Swede, though he varied the application of them. In his 'Introduction to Natural History' (1777), in which he commences with the *Infusoria*, and concludes with the *Mammalia*, the *Amphibia* form the tenth tribe, and are divided by him into the true *Amphibia* (Reptiles and Serpents), and false or Ichthyomorphous *Amphibia* (the Chondropterygian fishes). The true Amphibia are separated into Serpents and Reptiles, and the latter are subdivided into two orders, viz those which possess a tail, and those which are deprived of that member (*Ecaudata*). The genera do not differ from those of Linnæus, though the characters of them are otherwise defined, but not improved. Scopoli, in his admiration of the brevity of his great master, has carried his own to the very verge of obscurity.

The Count Lacépède (1788, 1790) divided the Reptiles into three great groups:—

I. *Oviparous Quadrupeds*, subdivided into (1) those which possess a tail, and (2) those which are tailless.

II. *Biped Reptiles*.

III. *Serpents*.

Of the tailed oviparous quadrupeds the Tortoises form the first genus, and are separated into two sections:—1st, —those whose toes are united, unequal, and flattened into fins (the Marine Tortoises or Turtles); 2nd, those whose toes are short and moveable, and nearly equal (Fluviatile and Terrestrial Tortoises)—twenty-four species in all. [TORTOISES.]

The second genus, comprising the Lizards, consists of those reptiles which have no carapace; they are divided into eight sections or subgenera—the Crocodiles, Tupinambis, Iguana, the true Lizards, the Chameleons, the Geckos, the Chalcides, the Dragons, and the Salamanders—fifty-six species in all.

The second section of the Oviparous Quadrupeds consists of the Frogs and Toads, which are divided into three genera, containing thirty-three species. [FROGS, vol. x., p. 495.]

The second great group, or the Oviparous Bipeds, comprehends those reptiles which have two feet and a tail, and is subdivided into—1st, those which are provided with anterior feet only; 2nd, those which are furnished only with posterior feet.

The third great group, or the Serpents, consists of those reptiles which have neither feet nor fins: they include nine genera. [SERPENTS.]

But the genera recorded in the system of Lacepède are not the only genera which he has established. Many of a date posterior to that of his system will be found in the *Annales du Muséum* and other works; but in the former principally.

In 1799 the method of Mr. Alexandre Brongniart was read to the French Academy of Sciences, and it seems to have been first published in the 'Bulletin des Sciences,' in 1800; it was afterwards printed among the other Memoirs of the National Institute. His classification may be regarded as a considerable step in advance of those who had preceded him, and had principally confined themselves to external characters, well defined doubtless, but of little moment when compared with those based on organization and habits. Whilst they carefully attended to the presence or absence of tail or feet, they neglected those essential points which spring from generation and development. Brongniart pointed out the approximation of the Tortoises to the Lizards, and even to the Serpents, and was the first to show that the Toads, Frogs, and Salamanders ought to constitute a separate order.

The following are the orders of M. Alex. Brongniart:—

I. *Chelonians* (Tortoises). These are toothless as far as regards implanted teeth, but their jaws are covered with a trenchant horny substance; their body is protected by a convex carapace; their heart has two auricles; their stomach is more voluminous than that of other reptiles, and their intestinal canal is provided with a cæcum;* they copulate, and lay eggs with a solid calcareous covering. The principal nourishment of this order is derived from vegetables.

II. *Saurians* (Lizards). These have implanted teeth, two auricles to the heart, ribs, and a sternum. The male has an external organ of generation, and they perform a true copulation; they lay eggs with a calcareous shell, and the young do not undergo a metamorphosis.

III. *Ophidians* (Serpents). These have long arched ribs. The male has an internal organ of generation; but they perform a true copulation, and lay eggs with a calcareous shell, and their young are hatched in all respects like the parents. They differ from the Saurians in having a heart with but one auricle,† no sternum, a double penis in the male, the shell of the egg soft though calcareous, and no feet.

IV. *Batrachians*. These have but one auricle‡ to the heart, and no ribs, or the rudiments of ribs only, a naked skin without scales, and no feet. The male has no external organ of generation, and no true copulation takes place; the eggs being most frequently fecundated out of the body of the female, are shell-less, and laid in the water. The young are hatched with branchiæ or gills, and in the early stages of their existence differ from their parents.

The method of Lacépède seems to have found more favour in the eyes of M. Latreille than that of M. Alex. Brongniart, which last must have been known to the former when he published his 'Natural History of Reptiles,' in 1801 He places in his *first* division the Oviparous Quadrupeds whose body is provided with feet, dividing them into two

* An error, the *Pipa* is not an exception. [FROGS, vol. x., p. 496.]

* This exists as an exception in the *Chelonia*.

† All serpents are now known to possess two auricles.

‡ But it is divided internally into two chambers.

sections, according as they have unguiculated or clawless toes, and a scaleless skin. His *second* division is formed by the Serpents; and in his *third*, designated by the name of *Pneumobranchians*, he places the genera *Proteus* and *Siren*, as well as another, which he names *Ichthyosaurus*, which last is only a Tadpole.

In 1825, when the science had very much advanced, M. Latreille, in his 'Families of the Animal Kingdom,' published another arrangement, which MM. Duméril and Bibron have digested into the following table:—

HEMACRYMES PULMONEES.

Classes. Sections. Orders. Families.

- Reptiles
  - Cuirassed
    - Chelonians: Cryptopods (Testudo, &c.). Gymnopods (Saurochelys, Trionyx, &c.).
    - Emydosaurians: Crocodilians (Crocodiles, &c.).
  - Scaly
    - Saurians
      - Lacertiform: Lacertians (Monitor, &c.). Iguanians (Iguana, &c.). Geckotians (Gecko, &c.). Chameleonians (Chamæleo, &c.).
      - Anguiform: Tetrapods (Scincus, Seps, Chalcides). Dipods (Bipes, Bimanus). Apods (Anguis, Ophisaurus, &c.).
    - Ophidians
      - Idiophids: Amphisbænians (Amphisbæna, &c.). Cylindrical (Tortrix). Coluberians (Acrochordus, Boa, Python, &c.). Anguivipers (Bongarus, Hydrophis, Pelamys, &c.). Vipers (Crotalus, Berus, Naja, &c.).
      - Batrachophids: Gymnophids (Cæcilia).
- Amphibia
  - Caducibranchians: Anurous (Pipa, Bufo, Rana, &c.). Urodeles (Salamandra, Triton, Axolotl).
  - Perennibranchians: Ichthyoids (Proteus, Siren).

In 1802 and 1803 appeared the 'Traité Général' of Daudin. In this distinguished work (for with some faults, which a happier state than fell to the lot of the unfortunate author [DAUDIN] might have prevented, distinguished it is and will be) the method of M. Alexandre Brongniart is followed, in so far as the division of the Reptiles into four orders. In the three sections of *Chelonians* fifty-seven species are named and described. In the order *Saurians*, Daudin first places *Crocodilus*, with its three subgener. [CROCODILE], and then the genera *Draco*, *Tupinambis* (in which he describes several new species), *Lacerta* (subdivided into the Ameivas, the Collared, Ribanded, Spotted, Gray, Dracenoid, and Striated Lizards—thirty-one species in a.. and including the genera *Trachydromus*, *Draco*, *Basiliscus* and *Agama* (which last is subdivided into five sections), *Seps*, and *Chalcides*. The third order, *Ophidians*, contains numerous and natural genera, some of them rather overloaded, *Coluber* for instance, under which one hundred and seventy-two species are arranged; and others with only one or two. The fourth order, *Batrachians*, appears to have employed his particular attention. [FROGS, vol. x., p. 4.. He includes *Salamandra* and *Triton* in one genus, and assigns a single species to the genera *Proteus* and *Siren*. Such is a mere sketch of the great work of Daudin, founded, as he himself declares, upon his personal examination and study of five hundred and seventeen species.

In the short notice published by George Cuvier, in his 'Tableau Elémentaire de l'Histoire Naturelle' (1798), he divided the Reptiles, like Lacépède, into *Oviparous Quadrupeds*, *Serpents*, and *Biped Reptiles*. Even at this early period we trace the enlarged and penetrating character of the mind of this great zoologist in the leading idea of making the organization of animals the basis of their classification, in the new views regarding the divisions of the orders, and the important reformation in the characters assigned to certain genera up to that time. In 1817, when the first edition of his 'Règne Animal' was given to the world, we find that he had not neglected the interval which had thrown so much light on this branch of zoology, and that, abandoning entirely the systematic divisions which he had adopted in his 'Tableau Elémentaire,' he founds the whole of his arrangement on the structure of animals and their external and internal conformation. In 1829, when the second edition, the last which received his own revision, of the 'Règne Animal' appeared, we find this classification retained, with some slight corrections; and the following is a synoptical table of his method as applied to the Reptiles:—

Orders. Families.

- Heart with an Auricle
  - Double
    - Limbs: Jaws
      - Horny, without teeth . . . *Chelonians* . . . Chelonians.
      - Toothed . . . *Saurians*. . . . Feet
        - Ordinary: toes to the number of .
          - Five before, four behind . . . Crocodilians.
          - Five to four feet: Tongue
            - Bifurcated, extensible . . Lacertians.
            - Not extensible: Body
              - Ordinary. . Iguanians.
              - Flattened . Geckotians.
            - Vermiform, very extensible. Chameleonians.
        - Very-short, or to the number of four at least . . . . Scincoidians.
    - No Limbs . . . . . . *Ophidians*. . . Skin
      - Scaly: eye.
        - With three eyelids . . . Anguis.
        - Without a third eyelid . . True Serpents.
      - Naked . . . . Naked Serpen..
  - Single. . . . . *Batrachians* . . . Batrachians.

Most of the leading genera and subgenera belonging to these families will be found under their several heads in this work. We will here only call attention to the *Batrachians*.

Genera. Subgenera.

- Tail
  - None. Rana. . . . Rana, Ceratophrys, Dactylethra, Hyla, Bufo, Bombinator, Rhinella, Otilophus, Pipa.
  - Long. Feet to the number of . .
    - Four
      - Lungs without branchiæ . Salamandra. . . . Terrestrial and Aquatic Salamanders, Menopoma, Amphiuma.
      - Branchiæ and lungs. Proteus. . Axolotl.
    - Two . . . . . Siren . . .

Oppel (who had been a diligent attendant at M. Duméril's course of lectures in 1807 and 1808, and in whose works much of the lessons of the latter are to be traced, as Oppel himself acknowledges), after publishing, in the nineteenth volume of the *Annales du Muséum*, a Memoir on the Ophidiens, and another on the Batrachians, produced in 1811, at Munich, his treatise *Die Ordnungen, Familien, und Gattungen der Reptilien als Prodrom einer Naturgeschichte derselben* (thin 4to.).

The following synoptical table exhibits Oppel's method:—

- Reptilia
  - Testudinata: Chelonii. Emydæ.
  - Squammata
    - Saurii: Crocodilini. Geckoidea. Iguanoidea. Lacertini. Scincoidea. Chalcidica.
    - Ophidii: Angui formes. Hydri. Crotalini. Viperini. Constrictores. Pseudo-vipera. Colubrini.
  - Nuda: Apoda. Caudata. Ecaudata.

Other writers besides Oppel have evidently profited by the lectures of M. Duméril, who promises, at the end of the excellent *Erpétologie* by himself and M. Bibron, now in the course of publication, a complete table, setting forth his ideas on this branch of zoology. Those ideas, as far as can be collected from the parts already before the public, are sound and philosophical; being marked by acute observation, minute detail, and deep research, which are made subservient to general and enlarged views of the whole subject.

In 1790 Merrem published a paper in German, with the title of *Materials for a Natural History of Amphibia*,* and in 1820 and 1821 two other papers followed. These papers treat of serpents and several genera of Saurians, and are illustrated with coloured plates. But his system appears to have been published (in 1800) at the suggestion of Bechstein, who had translated Lacépède's 'History of Reptiles' into German; and in 1820 a second edition of this system, which is shown in the following table, made its appearance:—

Classes.	Orders.	Tribes.	Subdivisions.
Pholidota	*Testudinata*:	with feet	Pinniform. Digitated.
	Loricata (Crocodiles)		
	Squammata	Gradientia	Ascalabotæ. Sauræ. Chalcidici.
		Repentia (Anguis, Ophisaurus, Acontias).	
		Serpentia	Gulones. { Innocui. Venenati. } Typhlini.
		Incedentia (Chirotes).	
		Prendentia (Chamæleon).	
Batrachia		Apoda (Cæcilia).	
		Salientia (Rana, &c.).	
		Gradientia with eyelids	Mutabilia (Salamandra, &c.).
		Gradientia without eyelids	Amphipneusta (Hypochton, or Proteus).

M. de Blainville, in 1816, published, in the *Nouveau Bulletin des Sciences de la Societé Philomatique*, the prodromus of his systematic distribution of the animal kingdom, which he produced, in 1822, in his *Principes d'Anatomie Comparée*. Under the type *Osteozoaria* and the subtype *Ovipara* or *Amastozoaria*, he places the reptiles, which he divides into two classes, viz.: 1, *Reptiles* or *Ornithoïd Squammifers*; 2, *Amphibians* or *Nudipellifers*, *Naked Ichthyodians*.

The first class is separated into three orders:—

I. *Chelonians*, consisting of the genera *Testudo*, *Emys*, *Chelys*, *Trionyx*, *Chelonia*, and *Dermochelys* (Sphargis).

II. *Emydosaurians*, or crocodiles, divided into three subgenera.

III. *Saurophians* or *Bipenians*, which are separated into two suborders:—

A. *Saurians*, consisting of the families of Geckoidians, Agamoïdians (the Normal, as *Agama* and *Basiliscus*, and the Anormal, as *Chamæleo* and *Draco*), the *Iguanoïdians*, *Tupinambis*, and the *Lacertoidians* (divided into *Tetrapods*, *Dipods*, and *Apods*).

B. *Ophidians*, which are divided into

1. The *Dipods* (Chirotes).
2. *Apods*—*a* (with numerous teeth), *Pelamys*, *Hydrophis*, the *Vipers*, and the *Lethifers*—*β* (without venomous teeth), the *Amphisbænas*, the *Climbers* or *Boas*, and the *Colubers*.

The second class, *Ichthyoid* or *Nudipelliferous Amphibians*, is composed of four orders:—

1. The *Batrachians*, divided into two suborders—*a* (Aquiparous), *Rana*, &c.; *β* (Dorsigerous), *Pipa*.
2. The *Pseudosaurians* or Salamanders.
3. The *Subichthyans* or True Amphibians (*Proteus*, *Siren*).
4. The *Pseudophidians* (*Cæcilia*).

Mr. John Edward Gray published, in 1825, his *Synopsis of the Genera of Reptiles* and *Amphibia*, in the *Annals of Philosophy*. He considers the *Reptiles*, or scaly-skinned group, and the *Amphibia*, or naked-skinned group, as distinct classes.

The class *Reptilia* are thus defined:—Body covered with scales or hard plates imbedded in the skin; heart with two auricles and one ventricle, respiring by lungs. The blood is cold; the windpipe ringed; the ribs are perfect, and there are several vertebræ; the penis is distinct, sometimes double. The egg is covered with a shell, mostly hatched in the body of the mother.

* Beiträge zur Naturgeschichte der Amphibien'

The orders of the *Reptilia* are divided into two sections

1.

Body covered with imbedded hard plates.

Ears closed with a valve . . . . . Emydosauri.
Ears naked, valveless . . . . . . Sauri.

2.

Body covered with scales, or two large shields

Legs 2—4 weak; ears naked . . . Saurophidii.
Legs 0; ears 0 . . . . Ophidii.
Legs 4; body covered with two shields . Chelonii.

Mr. Gray then remarks that 'Mr. Macleay, in his excellent *Horæ Entomologicæ*, has observed that the order of this class appears to assume a circular disposition; the most visible break in this arrangement is in the passage between the snakes and the tortoises; for the connection between the latter order and the crocodiles must be visible to every one, if they only consult Shaw's figures of the *Testudo serpentina*, and compare it with that of the crocodile, for it is in fact a crocodile with a shortened body, covered with united instead of distinct shields, and a bird's beak. The passage from the crocodiles to the lizards by means of the monitors has been long known to naturalists, who have often considered the latter as species of the former genus; and even Linnæus placed them in the same section of his genus Lacerta. The Scincs have always been placed in the same genus or group with the lizards; but their affinity with the slow-worms did not escape the penetrating eye of Linnæus, who observes that the *Lacerta Chalcides* is 'Media inter Lacertas et Angues,' and the union of the genera *Scincus*, *Anguis*, and *Amphisbæna* into an order, although it has not been done by any zoologist that I am aware of, appears to be strictly natural, for the feet in this order exist in such various degrees of development, that the being with or without them appears to be only a family or generic character, and not ordinal. Linnæus placed the genera *Tortrix* and *Eryx* of the true serpents as species of his genus *Anguis*, thus showing that he considered them as nearly allied. So far the passage from one order to the other has been very easy and gradual; and indeed sometimes I have been doubtful, as in the last case, to which order I should refer the genera. There is every reason to believe, from general structure, that there exists an affinity between the tortoises and the snakes; but the genus that exactly unites them is at present unknown to European naturalists, which is not astonishing when we consider the immense number of undescribed animals which are daily occurring. Mr. Macleay thought that these two orders might be united by means of *Emys longicollis* (the long-necked tortoise) of Shaw; but the family to which this animal belongs appears to be the one which unites this class to the crocodile: if I may be allowed to speculate from the peculiarities of structure which I have observed, I am inclined to think that the union will most probably take place by some newly discovered genera allied to the marine or fluviatile soft-skinned turtles and the marine serpent.'

Mr. Gray then proceeds to develop his system as follows:

§ 1. *Body covered with imbedded hard plates; legs distinct, fit for walking.* Loricata, *Gray*, not *Merrem*.

Order I. *Emydosauri*, Blainv.

Ears closed by two longitudinal valves; anus longitudinal; body covered with large imbedded plates; tongue short, adnate; legs four; toes four before, five behind; sternum long; clavicles none; lungs not extended to the abdomen; *living in or near water*.

Families: 1. *Crocodilidæ*. 2. *Ichthyosauridæ*. 3. *Plesiosauridæ*.

Mr. Gray thinks that *Megalosaurus* of Buckland is, perhaps, allied to this order.

Order II. *Sauri*, Blainv.

Drum of the ears naked or covered with skin; anus transverse; body covered with large and small imbedded scales; legs four, toes five, before and behind; sternum short; clavicles distinct; lungs extended into the abdomen; *living mostly on land*.

§ I. *Tongue not extensile.* Ascalabota, Merrem.

Families: 1. *Stellionidæ*. 2. *Geckotidæ*.

§ II. *Tongue extensile.* Sauræ, Merrem.

Families: 3. *Tupinambidæ*. 4. *Lacertinidæ*. 5. *Chamæleonidæ*.

Order III. *Saurophidii*, Gray.

Drum of the ear deep-seated, partly covered with a posterior transverse valve or by the skin; eyes furnished with longitudinal eyelids; skin covered with uniform imbricate scales, or rings of square plates; feet two, or four, small, weak, sometimes wanting; occipital condyle three-cut; lungs two, unequal, or rarely only one; ossa quadrata one on each side;* upper maxilla immoveable.

§ I. *Body covered with imbricate scales; anus transverse, not terminal; tongue extensile.*

Families: 1. *Scincidæ*, Gray. 2. *Anguidæ.*

§ II. *Body covered with intricate* (imbricate?) *scales; anus terminal.*

Family: 3. *Typhlopidæ*, Gray.

§ III. *Body covered with rings of square scales.*

Families: 4. *Amphisbænidæ*, Gray. 5. *Chalcididæ.*

Order IV. *Ophidii*, Brongn. (Serpentes, Linn.)

The drum of the ear wanting; eyes destitute of the third lid; skin covered with imbricate scales or plates; feet none; chest and blade-bones wanting; ribs encircling the body; body of the vertebra uniting by a convex and a concave surface; the os tympanum or pedicel of the lower jaw moveable, and suspended to another similar bone or mastoid, attached to the skull only by ligaments. The branches of the jaw only united together by ligaments, so as to let them separate more or less from each other, and allow the animal to swallow large bodies; the palatine arches moveable, armed with sharp recurved teeth.

§ I. *Upper jaws with fangs only.* Venati. (Venenati must be meant.)

Families: 1. *Crotalidæ.* 2. *Viperidæ.*

§ II. *Upper jaw with teeth, and with or without fangs; oviparous.*

Families: 3. *Hydridæ.* 4. *Colubridæ.* 5. *Boïdæ.*

Order V. *Chelonii.* (Testudinata, Oppel.)

Body short, enclosed between two horizontal shields, with the head, neck, tail, and four legs, passing out between; mouth toothless, often covered with a horny bill; tongue short.

§ I. *Feet and head retractile into the carapace; carapace solid, covered with horny scales.* Cryptopodi.

Families: 1. *Testudinidæ.* 2. *Emydidæ*, Bell.

§ II. *Feet and head not or only partly retractile into the carapace; carapace mostly soft.* Gymnopodi.

Families: 3. *Trionycidæ.* 4. *Sphargidæ.* 5. *Chelonidæ.*

Our limits have compelled us to confine ourselves to the orders and families: the subfamilies, the genera, and their subdivisions as marked out by Mr. Gray will be given under their respective heads.

The following table of the affinity of Reptiles is given by this zoologist:—

Normal Groups.	*Annectant Groups.*
Order I.—*Sauri.*	
1. Stellionidæ.	3. Lacertinidæ.
2. Geckotidæ.	4. Chamæleonidæ.
	5. Tupinambidæ.
Order II.—*Emydosauri.*	
1. Crocodilidæ.	3. Plesiosauridæ.
2. ————	4. Ichthyosauridæ.
	5. ————
Order III.—*Chelonii.*	
1. Testudinidæ.	3. Trionycidæ.
2. Emydidæ.	4. Sphargidæ.
	5. Carettidæ (Cheloniadæ?).
Order IV.—*Ophidii.*	
1. Crotalidæ.	3. Hydridæ.
2. Viperidæ.	4. Colubridæ.
	5. Boidæ.
Order V.—*Saurophidii.*	
1. Scincidæ.	3. Typhlopsidæ.
2. Anguidæ.	4. Amphisbænidæ.
	5. Chalcidæ.

The class *Amphibia* are thus defined:—Body with a soft naked skin; heart with one auricle and one ventricle; respiring by lungs and gills, and often by lungs only when perfect; claws none; head articulative to the vertebra by two condyles. Blood cold; windpipe membranaceous; ribs none, or very short and imperfect; egg-skin membranaceous. Animal often changes its form and habit during growth; eggs fecundated after they are deposited, hatched in the water where they are laid. They do not only differ from the perfect animal by having gills, but they often change their external and internal conformation, and generally gain legs.

The following are the orders and families under which Mr. Gray arranges the genera:—

§ I. *Undergoing transformation; gills deciduous; eyelids three, distinct; spiracles none.* Mutabilia, Gray. The larva elongated, respiring by deciduous gills.

Order I. *Anoura*, Dum. (Salientia, Laur.; Batrachians, Blainv.).

Families: 1. *Ranidæ* (subfamilies *Hylina*, *Ranina*, *Bombinatorina*), *Piprina* (Pipina?), *Bufonina.*

Order II. *Urodela*, Dum. (Caudata, Oppel.; Pseudosaurii, Blainv.).

Family: 2. *Salamandridæ.*

§ II. *Not undergoing any transformation; gill none or permanent; eylids two; spiracles distinct.* Amphipneusta.

Order III. (Sirenes, Linn.)

Families: 3. *Sirenidæ* (subfamilies *Proteina*, *Serenina*, (Sirenina?). 4. *Amphiumidæ.*

Order IV. (Apoda, Merrem; Pseudophidii, Blainv.)

Family: 5. *Cæciliadæ.*

In 1831 the same author published, in Griffith's Cuvier (vol. ix.), a 'Synopsis of the Species of Reptiles,' in which he made some alterations in his first classification. He there places the order Testudinata in the first section (*Cataphracta*), and distributes the genera nearly in the same manner adopted by him in his separate publication, 'Synopsis Reptilium,' where he particularly treats of the *Chelonians.* In the second section (*Squamata*) he arranges the Saurians, Ophisaurians, and Serpents.

For the Saurians he adopts Wagler's divisions, depending on the form \of the tongue and the manner in which the teeth are placed in the jaws.

The *Amphibia* are still classed separately: in the second section (*Amphipneusta*), which undergoes no metamorphosis, are placed the *Protei*, comprehending *Hypochton*, *Menobranchus*, *Phyllidra*, or *Siredon*, *Siren*, to which Mr. Gray approximates the *Pseudobranchians*, *Amphiuma*, to which he approximates the *Abranchians* (*Protonopsis*, Barton), and the *Cæciliæ* (*Siphonops*, Wagler; *Ichthyophis*, Fitzing.; and *Epicrium*, Wagler).

In the *Synopsis of the Contents of the British Museum* (1840), Mr. Gray has again considerably modified his method, and, as we think, improved it. The *Reptilia* forming the third class are thus arranged.

§ I. Squamata.

Order I. Sauria.

A. *Leptoglossæ.*

Families: 1. *Monitoridæ.* 2. *Helodermidæ.* 3. *Teidæ.* 4. *Lacertinidæ.* 5. *Zonuridæ.* 6. *Cercosauridæ.* 7. *Chirocolidæ.* 8. *Chamæsauridæ.* 9. *Chalcidæ.* 10. *Scincidæ.* 11. *Gymnophthalmidæ.* 12. *Pygopidæ.* 13. *Rhinidæ.* 14. *Acontiadæ.* 15. *Typhlopsidæ.*

B. *Pachyglossæ.*

Families: 16. *Geckotidæ.* 17. *Iguanidæ.* 18. *Agamidæ.* 19. *Chamæleonidæ.*

Order II. Ophidia.

A. *Venenosa.*

Families: 1. *Crotalidæ.* 2. *Viperidæ.*

B. *Innocua.*

Families: 3. *Colubridæ.* 4. *Boidæ.* 5. *Hydridæ.*

§ II. Cataphracta.

Order III. Chelonia.

Families: 1. *Testudinidæ.* 2. *Emydæ.* 3. *Chelydæ.* 4. *Trionycidæ.* 5. *Cheloniadæ.*

Order IV. Emydosauri.

Family: *Crocodilidæ.*

Order V. Amphisbenia.

Families: 1. *Trogonophidæ.* 2. *Chirotidæ.* 3. *Amphisbænadæ.*

* Common to Reptiles generally; as well as to other animals which have an os quadratum.

With the exception of the Paris collection, that of the British Museum is more rich in *Reptilia* than any other public or private museum.

MM. Carus and Ficinus have, in their zoological arrangement, adopted very nearly the classification of Merrem and the principles of Oken for the Reptiles.

In the method proposed by Dr. Harlan, in the 'Journal of the Academy of Natural Sciences of Philadelphia,' he adopts the four orders of *Batrachians, Ophidians, Saurians,* and *Chelonians.*

The Batrachians are divided into three sections, or suborders, according to the respiratory functions. In the first suborder the opercula are indicated by a slit in the cuticle, as in *Amphiuma* and *Menopoma.* In the second division the persistent branchiæ are present, and there are many slits in the skin of the neck; this division includes *Siren* (3 species) and *Menobranchus* (2 species). In the third the species have lungs only in the adult state, so that the branchiæ and their slits disappear; the tail is persistent, and there are teeth in both jaws (*Salamandra, Triton, Frogs,* and *Toads*).

In the dichotomous or binary method proposed by Mr. Haworth (*Philosophical Magazine*), there is little more to be observed than that the labours of preceding writers, especially Merrem, are carried out in it, as indeed he himself allows.

The 'Neue Classification der Reptilien' of Fitzinger was published at Vienna, in 1826. This work, the result of much anatomical and physiological study, has always held a prominent place in the history of Herpetology, and its leading principles will be seen in the following table:—

Classes.	Orders.	Tribes.	Families.
Reptilia.	Monopnoa.	I. Testudinata	1. Carettoides. 2. Testudinoides. 3. Emydoides. 4. Chelydoides. 5. Trionychoides.
		II. Loricata.	6. Ichthyosauroides.* 7. Crocodiloides.
		III. Squammata	8. Ascalabotoides. 9. Chamæleonides. 10. Pneustoides. 11. Draconoides. 12. Agamoides. 13. Cordyloides. 14. Tachydromoides. 15. Ophisauroides 16. Chalcidoides. 17. Ameivoides. 18. Lacertoides. 19. Scincoides. 20. Anguinoides. 21. Amphisbænoides. 22. Typhlopoides. 23. Gymnopthalmoides. 24. Ilysioides. 25 Pythonoides. 26. Colubroides. 27. Bungaroides. 28. Viperoides. 29. Crotaloides. (*Saurians* and *Ophidians.*)
		IV. Nuda	30. Cæcilioides.
	Dipnoa.	V. Mutabilia	31. Ranoides. 32. Bufonoides. 33. Bombinatoroidea. 34. Pipoides. 35. Salamandroides.
		VI. Immutabilia	36. Cryptobranchoidea. 37. Phanerobranchoides.

In 1828, Ritgen's classification of Reptiles appeared in the 'Nova Acta Nat. Cur.,' to which we refer those of our readers who may wish to consult it. This classification is not much attended to. Not that it is inexact, but the author crowds particulars under one general denomination to excess; and his nomenclature is absolutely forbidding. The words *Chersopholidophides, Hydropholidophides,* and *Cacopholidophides,* used to designate groups of Serpents; and *Stallipodobatrachians, Phyllopodobatrachians,* and *Didactylobatrachians,* to distinguish groups of Frogs and Toads, may be taken as examples of the terms fabricated by Ritgen, and he uses some still less euphonous.*

Wagler, whose early and violent death deprived zoological science of one of its brightest ornaments, published his 'Naturalisches System der Amphibien,' founded upon the organization of the animals, at Munich, in 1830.

In this system the *Amphibia* consist of eight orders:—

I. The Tortoises. II. The Crocodiles. III. The Lizards. IV. The Serpents. V. The Orvets. VI. The Cæciliæ. VII. The Frogs; and VIII. The Ichthyodes.

The *Tortoises* (*Testudines*) consist of but one family, *Hedræoglossæ,* having the tongue attached to the whole concavity of the jaw, which comprises three tribes, distinguished by the structure of the feet. 1, *Oiacopods,* or those with fin-shaped feet; 2, *Steganopods,* or those with moveable toes, united by a loose membrane; and 3, the *Tylopods,* or those whose toes are immoveable, of the same length, and enveloped in the skin of the feet.

II. The *Crocodiles* consist of the Caimans (*Champsa*), the true Crocodiles (*Crocodilus*), and the Gavials (*Ramphostoma*); and here he would place the fossil genera *Teleosaurus, Steneosaurus, Saurocephalus,** and *Phytosaurus.*

III. The *Lizards.* These consist of four families: 1, the *Platyglossæ,* or those whose tongue is fleshy, flat, and free at the top; 2, *Pachyglossæ,* those whose tongue is thick and nearly entirely adherent to the concavity of the jaw; 3, *Antarchoglossæ,* whose tongue is slender, free, and extensile, but is not enclosed in a sheath at its base; 4, *Thecoglossæ,* whose exsertile tongue enters at its base into a kind of sheath.

The genera belonging to this order are extremely numerous, and some of the families are divided into tribes according to the form of the body, or the manner in which the teeth are disposed upon the edges of the jaws.

IV. The *Serpents,* consisting but of one family, comprise ninety-seven genera.

V. The *Orvets* (*Anguis*), consisting but of one family, comprehend the genera *Acontias, Chirotes, Chalcis, Lepidosternon, Amphisbæna,* and *Blanus.*

VI. The *Cæciliæ,* consisting also but of one family (*Hedræoglossæ*), comprise the genera *Siphonops, Cæcilia,* and *Epicrium*).

VII. The *Ranæ* are divided into two familes, the *Aglossæ* and the *Phaneroglossæ.*

VIII. The *Ichthyodes,* comprehending but one family *Hedræoglossæ*) consist of the genera *Amphiuma, Siredon* (Axolotl), *Hypocthon* (Proteus), *Necturus, Menobranchus,* and *Siren.*

In 1832, Professor Müller of Bonn published his *Beiträge fur Anatomie und Naturgeschichte der Amphibien.* (*Zeitschrift für Physiologie von Tiedemann und Treviranus,* Heidelberg). Much interesting detail relating to the history of reptiles is here entered into, but the Professor treats more especially of the *Batrachians* and *Serpents.* He divides the *Amphibia* into two great orders, consisting of the *scaly* and the *naked.*

Scaly Amphibia.	*Naked Amphibia.*
Occipital condyle simple	Occipital condyle double.
True ribs . .	None or rudimental.
Auricle of the heart double . . .	Single.†
Internal ear with round and oval fenestræ .	Oval only.
With a distinct cochlea	None.
Penis of the males simple or double .	None.
No metamorphosis .	Most frequently a distinct metamorphosis.
No branchiæ . .	Distinct branchiæ, or with persistent or not permanent holes.
Skin scaly, scutcheoned or cuirassed .	Naked.

Professor Müller divides the *Serpents* in accordance with their anatomical structure.

The *Microstomes,* or those which have a not dilatable mouth, correspond very nearly to the *Homoderms* of M. Duméril. They are separated into four families: 1, the *Amphisbænoids;* 2, the *Typhlopins;* 3, the *Uropeltaceans;* 4, the *Tortricins.*

The second suborder (*Macrostomes*) corresponds with the *Heteroderms* of M. Duméril. These are divided into seven families: 1, the *Oligodonts;* 2, the *Holodonts* (*Python,* &c.); 3, the *Isodonts* (*Boa, Pseudoboa,* &c.); 4, the *Heterodonts,* (*Dendrophis, Coronella,* &c.); 5, *Amphiboles* (*Dryophis, Dipsas,* &c.); 6, the *Antiochalinans* (*Bongarus, Naja,* &c.); and 7, the serpents with three sorts of teeth, and in which all the mandibular teeth are perforated and venomous (*Elaps, Scytale, Crotalus,* &c.).

* It is said that Ritgen meant this essay as a sly satire on the increasing pedantry of naturalists; if so, it seems to have been a perilous joke, of which those who conduct the *Nova Acta* never dreamed; for they printed it in earnest, and so it has been received by zoologists.

* This is a sauroid fish.

† Davy, 'Edinburgh new Philosophical Journal,' 1828, discovered the double auricle in the Toad and Frog; and he is confirmed by Martin Saint-Ange, and Weber. Professor Owen has shown that though the auricle in the Siren appears simple, it is in fact separated into two by a complete septum.

The work is well illustrated, especially with good osteological and other anatomical figures.

In 1833, the first part of Schinz's *Naturgeschichte und Abbildungen der Reptilien* was published at Leipzic: in 1834 it was concluded. It brings down the information to the time of its publication, is well digested and well illustrated with coloured figures of the true reptiles and amphibians, mostly from good originals, but some from nature, and will be found very useful, especially as a book of reference.

Mr. Swainson (*Natural History of Fishes, Amphibians, and Reptiles*, in Lardner's *Cyclopædia*) places the *Amphibia* and the *Reptilia* in different classes.

He gives the following as 'a natural arrangement of the class of amphibia, according to Professor Bell:'—

Order I. Amphipneura (Amphipneusta?) (*Proteus, Siredon, Menobranchus, Siren, Pseudobranchus*). Order II. Anoura (Frogs and Toads). Order III. Urodela (*Salamandrina, Salamandra, Tritonella, Molge*). Order IV. Abranchia (*Menopoma, Amphiuma*). Order V. Apoda (*Cæcilia*).

The same author gives the following as a 'Synopsis and Natural Arrangement of the Class of Reptilia:'—

Order I. Emydosaures—*Crocodiles* (*Crocodilus, Champsa, Stenosaurus*). Order II. Chelonides—*Tortoises* (Families: Chelidridæ, *Crocodile Tortoises*; Testudinidæ, *Land Tortoises*; Emydæ, *River Tortoises*; Trionycidæ, *Soft Tortoises*; and Chelonidæ, *Sea Turtles*). Order III. Elanosaures (Enaliosaurs?)—*Fish Lizards* (*Plesiosaures, Icthyosaures, Saurocephalus, Pterodactylus*). Order IV. Ophides—*The Serpents* (Families: Hydrophidæ, *Water Serpents*; Crotalidæ, *Poisonous Serpents*; Coluberidæ, *Snakes not poisonous*; Anguidæ, *Slow-Worms*; and Amphisbænidæ, *Blind-Worms*). Order V. Saures—*The Lizards* (Families: Chamæleonidæ; Iguanidæ, *Thick-Tongued Lizards*; Lacertidæ, *Slender-Tongued Lizards*; Agamidæ; and Scincoidæ.

In the same year Professor Bell published his interesting *History of British Reptiles*. He considers the *Reptilia* and *Amphibia* as distinct classes, and justifies his opinion by a reference to their characters, which appear to him to be sufficiently marked and important to warrant their separation.

The Reptiles considered in Mr. Bell's history are necessarily limited, and the families *Cheloniadæ, Lacertidæ, Anguidæ, Colubridæ*, and *Viperidæ* are the only groups noticed. But, in his *Introduction*, the author delivers an opinion which, from his acknowledged skill in this branch of natural history, is worthy of all respect, and which is decidedly adverse to what has been called the Quinary system, a system regarded with an unfavourable eye by Continental zoologists generally, and by many in our own islands. 'Those,' says Professor Bell, 'who have made the most philosophical attempts to ascertain the natural system, the grand and harmonious plan upon which all organic creation is believed to have been formed, have concurred in considering the *Reptilia* as constituting a group of equal value in the vertebrate division of the animal kingdom with the *Mammalia* and *Birds*. It may be safely predicated that, if the system to which I more particularly refer be true, all the groups of equal rank must be founded upon characters of equal value and importance. That if, for instance, the group of Mammalia and that of Birds be equal to each other, each of the other classes—that is to say, every other group of the same rank—must be equal to each other; and also, that the subordinate groups in each of these classes must exhibit the same mutual relations in every case. But if it can be shown that in one class so called two *ordinal* groups exhibit as great a discrepancy in their relative plan of organization as any two classes do, then the relation of the former to either of the latter is not and cannot be the same as that which exists between the latter two. Yet in this predicament stand the three first classes of the *Vertebrata*, the relation of the *Mammalia* and *Birds* being much stronger and more obvious than those of the *Reptilia* to either, and the two groups of the latter which I have just sketched, the *Tortoises* and the *Serpents*, being nearly or quite as far removed by their structure from each other as the *Birds* are from the *Mammalia*. The mode of reproduction is the sole exception of consequence to this view of their relations; and here we have, on the other hand, a close approximation between the *Reptilia* and the *Birds* themselves.

'These considerations appear to me to exhibit insurmountable objections to the consistency and unity of the Quinary arrangement, as representing a uniform and perfect plan or system upon which the animal kingdom was created; and I cannot believe that the occasional occurrence of even striking and important coincidences, which appear on a partial view to prove its truth, are sufficient to counterbalance the evidence of its inconsistency which I have just adduced.'

But the Professor, not without reason, as it appears to us, goes further. 'The relations of these groups' (he has been contrasting the widely different forms in some of the groups of Reptiles) 'seem almost to set all the established principles of classification at defiance; nor is there any one system hitherto promulgated which appears to me satisfactorily to solve the difficulty.'

Professor Bell thus arranges the class *Amphibia*:—

Order I. Anoura (*Rana, Hyla, Bufo*, &c.). Order II. Urodela (*Salamandrina, Salamandra, Molge*). Order III. Amphipneusta (*Proteus, Siren, Menobranchus*, &c.). Order IV. Abranchia (*Menopoma, Amphiuma*, &c.). Order V. Apoda (*Cæcilia*).

Mr. Bell states that he does not offer this arrangement either as wholly original or as absolutely natural; but he adds, that it appears to him to be less objectionable than the others which have been proposed.

We confess that, after some consideration and examination, we do not think that the organic differences between the true *Reptiles* and the *Amphibia*, as they are termed, are sufficient to warrant a separation into two distinct classes. The *Amphibia* may be considered as a division or subclass; but it is too much, in our opinion, to say that a Salamander (*Salamandra*) and a Sand Lizard (*Lacerta agilis*) belong to different *classes*.

Organization.

Motility.—The motion of *Reptiles* is as various as their structure, and exhibits a great diversity, particularly in its modes of progression. The slow march of the Land Tortoise, the paddling of the *Turtles*, the swimming and walking of the Crocodiles, the Newts, and the Protei, the agility of the Lizards, the rapid serpentine advance of the Snakes, the leaping of the Frogs, offer a widely extended scale of motion. If we add the vaulting of the Dragons and the flight of the Pterodactyles, there is hardly any mode of animal progression which is not to be found among the Reptiles.

Sensibility.—The senses in general are well developed in this class. Touch, taste, smell, hearing, and sight are present in a degree in all, though much more highly developed in some than in others. In *Typhlops*, for instance, the eyes are hardly visible, and in *Proteus* the development of the organ of sight appears to be at its minimum. The Lizards, Serpents generally, and Frogs, are very quick-sighted.*

Respiration.—The aëration of the blood is effected variously, either by lungs or gills, but by lungs principally, according to the condition of the Reptile or Amphibian. In the terrestrial Reptiles the air is, so to speak, swallowed; and in some an absorption of air as well as water (in the *Frogs*, for instance) takes place through the skin.

Nutrition; Reproduction of Injured Parts.—Digestion is performed very slowly, and the animals of this class are capable of very long fasts. In many, parts, when injured or entirely removed, are reproduced. In the Newts, for instance, an entire limb and even an eye has been replaced by the resources of the animal.

Generation.—The Reptiles are generally oviparous; but in some cases, those of the Viper, the Slow-Worm, the viviparous Lizard (*Zootoca vivipara*), for instance, they are ovoviviparous. In some, again, as in the Frogs, there is no intromittent male organ; in others, as in the Tortoises and Serpents, the intromittent organ is of considerable size.

Skeleton.—The skeleton of Reptiles is as variable as the very variable forms of the animals themselves. In some, the Crocodile for instance, the skull is a solid bony mass; in others, to take a Python or a Boa for instance, the cranium is composed of a great number of pieces so adapted as to admit of dislocation for the purpose of aiding in the dilatation of parts to facilitate the deglutition of a disproportioned prey. In some the ribs are so highly developed as to become organs of motion (the Serpents); in others (the Frogs), the ribs are entirely absent or rudimental. In some there is not only a true sternum, but also a sur-

* Excepting in the case of the serpents, a short time before the [illegible] change of skin.

abdominal sternum, apparently produced by the ossification of the tendinous portions of the recti muscles (Crocodiles). In others there is no sternum at all, though the ribs are well developed (Chamæleons). In some there are four well developed anterior and posterior extremities (Tortoises and Saurians); in others only two, and those not well developed (Chirotes, Bipes); in others none whatever (some of the Ophidians).

The leading differences in the organization of these animals are indicated under the articles treating of them in this work; but in the bones of all of them, whether true *Reptiles* or *Amphibia*, there is a peculiarity of character which enables the skilful comparative anatomist to pronounce at once that a bone is or is not the bone of a Reptile. This is of no small consequence, for it has enabled men so skilled to determine the class to which some of the most interesting and wonderful organic remains detected by the geologist and palæontologist belong.

FOSSIL *REPTILES*.

Of all the animals which the wrecks of a former world contain, none exhibit more striking, more gigantic proportions than the fossil Reptiles. As far as this work has hitherto gone, we have endeavoured to make some of these forms familiar to our readers [ICHTHYOSAURUS; IGUANODON; MEGALOSAURUS; PLESIOSAURUS; PTERODACTYLE; &c.]; and we shall continue to add any that may in future claim attention. We shall here merely remark, that there is reason for believing that Batrachians of gigantic dimensions once inhabited our planet.

REPUBLIC is derived immediately from the French *république*, and ultimately from the Latin *res publica*. The Latin expression *res publica* is defined, by Facciolati, to be 'res communis et publica civium una viventium,' and corresponds very closely with the English word *commonwealth*, as used in its largest acceptation for a political society. The Latin word *res publica* might be applied to a community under a monarchical government; thus Augustus is said, in a passage of Capito, a Roman lawyer, to have governed the *res publica* (Gellius, xiii. 12); the word however was more applicable to a society having a popular government than to a society having a monarchical government; thus Cicero denies that the name of *res publica* can be properly given to a community which is grievously oppressed by the rule of a single man: 'Ergo illam rem populi, id est rem publicam, quis diceret tum, quum crudelitate unius oppressi essent universi; neque esset unum vinculum juris, nec consensus ac societas cœtus, quod est populus' (*De Rep.*, iii. 31).

A *republic*, according to the modern usage of the word, signifies a political community which is not under monarchical government, or, in other words, a political community in which one person does not possess the entire sovereign power. Dr. Johnson, in his dictionary, defines a republic to be 'a state in which the power is lodged in more than one.' Since a republic is a political community in which several persons share the sovereign power, it comprehends the two classes of aristocracies and democracies, the differences between which are explained under ARISTOCRACY and DEMOCRACY.

The word *republic* is sometimes understood to be equivalent to *democracy*, and the word *republican* is considered as equivalent to *democratic*; but this restricted sense of the words appears to be inaccurate; for aristocratic communities, such as Sparta, Rome in early times, and Venice, have always been called republics.

It has been shown in MONARCHY that the governments usually styled 'limited monarchies' are properly aristocracies presided over by a king; and consequently ought to be referred to the class of republics, and not to that of monarchies, in which they are commonly placed. We observe however that the German writers, who know from their personal experience the character of monarchies strictly so called, sometimes correctly give the name of republican to the government of England since 1688, and to the government of France since 1814.

A vast deal of error and confusion of thought (leading to important practical consequences) has arisen from the capricious and indistinct usage of the words *monarchy* and *republic*.

REPUBLICATION. [WILL.]

REPULSION is that power by which bodies or the particles of bodies are made to recede from one another. Both attraction and repulsion exist in all the particles of material substances, and seem to be properties by which those particles act upon one another when not in contact. The cause of these actions will probably be for ever unknown to us, and the terms are only applied in conformity to the phenomena exhibited. At all sensible distances, bodies, small and great, except in certain states with respect to electricity or magnetism, attract one another; and the intensity of the attraction varies inversely as the square of the distance between the bodies. But the phenomena of light and of elasticity in general, show that at distances which are not appreciable by the eye (perhaps such as are less than [illegible] inch) both attractions and repulsions take place.

In his researches concerning the phenomena of light, Newton, having brought at one time a hair, and at another the edge of a knife, near a small beam of light in a darkened room, found that the particles of light were made to deviate from the rectilinear direction, as if attracted by a force which diminished with the distance of the ray from the hair or knife. The shadow of the latter was bordered with three coloured fringes, of which the nearest to it was formed by inflected rays passing at a distance rather greater than [illegible] inch from the knife-edge; and the second and third fringes by rays inflected respectively at greater distances. (*Optics*, lib. iii.) From these phenomena Newton was led to the opinion (which he proposes as a query) that all material bodies might be assemblages of particles in equilibrio between their mutual attractions and repulsions. He imagined also that a subtile æther, pervading material bodies, was the immediate agent in producing such attractions or repulsions, together with all the circumstances of cohesion, and also those of chemical, magnetical, and electrical actions. The phenomena of nature seem to justify the supposition that an æther pervades all bodies; but it must be admitted that the hypothesis of Newton only removes the difficulty concerning the actions of the particles of bodies a step further, since we are equally at a loss to account for the existence of the powers in those particles, and in the æther itself.

The reality of a distance between the particles of bodies, whether solid, fluid, or gaseous, admits of no question; for the differences in the densities of those classes of bodies can only be conceived to arise from the different extent of the intervals between the particles. By the process of cooling, all bodies, with certain exceptions in particular cases, become contracted in volume; and the mixing of two given volumes of different fluids (as water and sulphuric acid) produces a volume less than the sum of the two separate volumes. These effects manifestly depend upon the approach of the particles to one another, and are therefore inconsistent with the supposition that they were originally in contact.

It is natural to ask if there be such a thing as mathematical contact in nature, and it may be answered that we have no evidence of such a condition. [COHESION.] Besides the continual diminution of volume produced in the cooling of bodies, the Newtonian experiment of pressing a convex lens of glass upon the surface of a glass mirror affords evidence that the lens, at the point of nearest approach, and under a very great pressure, is not in contact with the mirror; and it has been supposed that the distance between them, at that place, is then not less than [illegible] inch. (Robison, *Mechan. Phil.*) It seems to follow that a vast force of repulsion must be in action between the particles of bodies when they are as near together as mechanical power can bring them; and it can be easily conceived that such repulsive force may be the immediate cause of the sensation of touch.

It has been said that the mixture of certain different fluids produces a diminution of volume, but it must be observed that a contrary effect frequently takes place. Some of the metals, when mixed together in a melted state, produce a volume greater than the sum of the component volumes; and melted metals, on becoming solid, like water on being frozen, expand in volume. The latter effect may arise from the crystals, on being formed, placing themselves across one another so as to leave comparatively large intervals; but the other can only be caused either by a diminution of the attractive power which the particles exert on one another, or by its being changed into a power of repulsion. One of these latter circumstances must also be the cause of the great augmentation of volume which takes place when the components of some bodies are disengaged from each other. It is said that if the parts of an olefiant gas were separated, the sum of the separate volumes would be four times as great as the volume of the compound. (Turner, *Elements of Chemistry*.)

It is right to observe that the word repulsion is often applied to phenomena which are in reality the results of attraction. A small quantity of quicksilver being laid on a glass plate assumes a spherical form, instead of spreading over it in a thin surface; and this was once supposed to arise from a repulsive power in the glass, whereas it is owing to the attraction of the particles of quicksilver for one another being greater than the attraction of the glass for the quicksilver. Again, when a small sewing-needle is placed on the surface of water, it remains there without sinking, and the water is depressed about the needle as if it were repelled by the steel; in fact however the trough is caused by the weight of the needle, which displaces the particles of water, but is not great enough to overcome their attraction for each other. Also, when two balls, one of them of glass, which is capable of attracting water, and the other of burnt cork, which is not, or only in a very small degree, are placed near one another in water, the latter seems to be repelled from the former; but the cause of the phenomenon is that the ring of elevated water about the glass assumes on the exterior a conical surface, so that when the cork ball is brought near enough to the other to be partly on the slope, it immediately slides off by its gravity.

The elasticity of bodies is a result either of attractive or repulsive powers, or both. For example, when a steel rod is bent, the particles on one side will be forced towards, and on the opposite they will be drawn from one another; in recovering itself, a force of attraction will be exerted on the latter side, and of repulsion on the other; and this may be considered as an evidence that in the insensible spaces between the particles of bodies attractions and repulsions prevail according as the distances between those particles are varied. While the change of figure in the rod is small, so that the displacement of any two particles is but a small part of their whole distance from one another, the attractions and repulsions exerted by the force applied are proportional to that force; and upon this principle depends the observed isochronism in the oscillations of a watch-balance, whatever be the extent of the arcs of vibration. The expansions of solids and fluids by heat, and the elastic powers of gas at different temperatures, are consequences of the repulsions residing in the particles of caloric, or induced by the latter in those of the bodies with which they are combined. [ELASTICITY; GAS; HEAT.] The repulsive power existing in the air which is condensed in nitre, produces, on being combined with heat, a velocity of expansion equal to about 7000 feet per second; and the force of pressure resulting from it is thought to be equal to 2000 times the pressure of the atmosphere. (Hutton, *Tracts*.) The repulsive force which produces some of the electric explosions in the atmosphere is supposed to be much greater. But the forces both of attraction and repulsion by which the particles of light are deflected from their course when they impinge on a refracting or reflecting surface are enormous; and Sir John Herschel computes that they exceed the force of gravity in the ratio of 2×10^{44} to 1. This is on the hypothesis of radiation; and that philosopher observes that on the undulatory hypothesis the numbers are equally high.

The circumstances of electrical attractions and repulsions are shown in the article ELECTRICITY; and the results of experiments prove that the intensities of these forces in the electric, galvanic, and magnetic fluids, like that of general attraction, vary inversely as the squares of the distances of the bodies.

Boscovich has ingeniously represented the series of alternate attractions and repulsions supposed to be experienced by a particle of matter within the very small distances between that particle and another, by a curve consisting of several bends crossing and recrossing an axis in points at various distances from the origin, which may be supposed to be the place of the second particle above mentioned. The ordinates of this curve on one side of the axis represent attractions, and those on the other side repulsions; the places of crossing being supposed to be those at which the first particle would be at rest. Beyond the small distance above mentioned, this axis becomes an asymptote to the curve, and the ordinates of the curve here represent the general law of attraction (the inverse square of the distances). Near the origin of the axis the ordinates represent repulsions; and those ordinates constantly increase till they become infinite, so that a right line drawn through the place of the second particle, perpendicular to the axis, is an asymptote to this branch of the curve.

REQUEST, COURTS OF (sometimes called *Courts of Conscience*), are local tribunals, founded by act of parliament to facilitate the recovery of small debts from any inhabitant or trader in the district defined by the act.

As all the acts are made upon the same model, the most easy method of explaining the functions of these courts will be to show the general provisions of those acts.

In the first place a board of commissioners is appointed, often in corporate towns consisting of one or two aldermen, with a certain number of householders as assessors. To this board is given the power of summoning a debtor upon the complaint of the creditor, of taking the evidence of the creditor and his witnesses upon oath, of determining on the amount due, and issuing a summons or order to the debtor to pay that amount, either in one sum or by instalments. Finally, they have usually the power of distress on goods, or of imprisonment during a limited time, if their order for payment is not obeyed. In London the jurisdiction is confined to cases where both parties are inhabitants, and the same restriction may be found in some of the older acts; but usually it is sufficient that the debtor should be an inhabitant, or should be 'seeking his livelihood' within the jurisdiction.

The sum to which the jurisdiction of these courts extends is usually 5*l*., often only 2*l*. (in London and Bath it is 10*l*.), and the debt may arise either upon simple contract, a balance of accounts, or as a compromise of a larger debt; but there is usually a proviso in the acts that a larger debt shall not be split into fragments to bring it within the jurisdiction of the court, although the creditor may reduce a larger demand to such a sum as the court can award, provided he is satisfied with the smaller amount in discharge of his whole debt.

The acts usually provide that if a party within the jurisdiction is sued in one of the superior courts, and the plaintiff recovers from him only the sum which the local court could have awarded, the plaintiff shall pay full costs to the defendant. The acts also reserve to a landlord the right to distrain for rent, and also prohibit the courts from interfering in matters touching the right to land or the occupation of it, or in matters belonging to ecclesiastical courts, or to tithes: usually, too, gambling debts are excluded, and sometimes tavern debts incurred on Sunday. The courts have jurisdiction over persons under age, and, on the other hand, can usually grant summonses for wages due to minors. Attorneys are not exempted from the jurisdiction of the court, but they are usually prohibited from practising in it, and they are not liable to payment of costs for suing in superior courts. Most of the acts contain a clause prohibiting the removing of the proceedings to superior courts.

The first Act for the establishing of a Court of Requests is the 1 James I., c. xv., confirming the court which had already been established in London by an act of the common council at least as early as the reign of Henry VIII., if indeed it had not been established by antient usage. (Tidd Pratt's 'Abstract of the Acts of Parliament relating to Courts of Request,' for a list of the places which have such courts.)

RE'QUIEM (*Requies*, Lat., *rest*), the name of a Mass sung in the Romish Church for the repose of the dead, beginning *Requiem æternam*, and in the Roman Catholic liturgy called *Missa pro Defunctis*.

RESCRIPT. [ROME—*Roman Law*.]

RESCUE, in Law ('rescous,' from the old French word *rescourser*, 'to recover'), is the unlawful and forcible setting at liberty a person or goods then in lawful custody. A rescue may be either a criminal offence or a civil injury, according to the circumstances under which it is effected. The character of the criminal offence is determined by the character of the offence committed by the person rescued. If, for instance, a party has rescued a traitor or a felon, he has committed the offence of treason or felony; but as the treason or felony of the person rescued cannot be assumed to have been committed until after his conviction and judgment, it is not proper to arraign the rescuer for such offence until after judgment of the principal offender. But it is said that the rescuer may be indicted for a misdemeanour even before such judgment.

A rescue committed under other circumstances than those above stated is a misdemeanour.

An indictment for a rescue must set out the circumstances under which the person, &c. was arrested, and the rescue effected, so as to show that all things existed necessary both in fact and intention to create the offence of rescue, and to enable the offender to disprove them.

Such was the state of the common law on this subject. Many statutes have been passed, some very limited in their application, which do not materially vary the character of the offence, the proceedings, or the punishment. Of these the most important and general in their application are 25 Geo. II., c. 37, relating to the rescue of a person convicted of murder, or his body after execution; 1 & 2 Geo. IV., c. 88, which applies to persons rescuing or assisting to rescue from the lawful custody of any constable or other person whatsoever any person charged with or suspected of or committed for any felony, or on suspicion thereof, and regulates also the amount of punishment to which a rescuer is liable; and 5 Geo. IV., c. 84, relating to the rescue of prisoners sentenced to transportation, by which also it is provided that the conviction of the principal offender may be proved by a certificate from the proper officer. The stat. 6 Geo. IV., c. 5, relates to the land-forces of her majesty, and c. 6, to marines.

Previously to the abolition of arrest on mesne process (1 & 2 Vic., c. 110), if a prisoner in custody of the sheriff on mesne process was rescued, the sheriff might make a return to that effect, which freed him from further responsibility. The rescuers were liable to an attachment for a contempt, and also to an action at suit of the plaintiff. On the action it was necessary to prove the original cause of action, the writ and warrant, and the arrest. To entitle himself to damages, the plaintiff must have shown the subsequent insolvency or disappearance of the defendant. The law as to this subject is probably still the same as to those cases where under the act in question an arrest is still permitted on mesne process.

Where a party arrested on judicial process, as upon a capias ad satisfaciendum, &c., or goods taken upon a fieri facias are rescued, the sheriff cannot return that there has been a rescue, and either he or the gaoler is in all cases, except where the rescue is effected by the king's enemies, answerable in an action by the plaintiff. This liability of the sheriff is concurrent with the liability of the rescuers themselves, the plaintiff having the option to sue either the rescuers or the sheriff.

By the 2 Will. & Mary, st. 1, c. 5, upon rescue of goods distrained for rent, the person grieved may by action on the case recover treble damages and costs against the offenders or any of them, or the owner of the goods, if found to have come to his use or possession. In an action under this statute the plaintiff must show the demise, the rent in arrear, and the rescue. In all cases, in order to constitute a rescue, the arrest must be lawful. Thus, if the rent due has been tendered before the distress is made, &c., then the custody of the goods, &c. being unlawful, no rescue can be committed.

(Com., *Dig.*, 'Rescous;' Hale, *P. C.*; Hawk., *P. C.*; Russell, *On Crimes*; Matthews, *On Criminal Law*.)

RESHT. [Persia.]

RESIDUAL, an expression which gives the remainder of a subtraction, as $a-b$.

RESIDUAL PHENOMENON, a term lately brought into partial use, to signify that part of a phenomenon which is left, when every part which can be explained or accounted for is removed. This residual phenomenon [Observation] may be all the observer's error, or may be partly the effect of some undiscovered law and partly the error of the observer.

RESIDUARY LEGATEE. [Legatee.]

RESIGNATION. [Benefice.]

RESIN (*Rosin*, *Colophony*). [Turpentine.]

RESINA. [Naples.]

RESINS are secretions of plants, which are probably all in a fluid state; but become solid either by the evaporation of their more volatile parts, or by the absorption of oxygen. They are distinguished from true balsams by the absence of benzoic acid [Balsams], and from gum-resins [Gum-Resins] by the absence of gum, their complete insolubility in water, and their requiring alcohol for perfect solution. Some are soluble in cold alcohol, and these are termed *resins*; others are soluble only in boiling alcohol, and termed *sub-resins*; but the two are often also associated in the same substance. Many volatile oils, by long exposure to the air, or merely by a reduction of temperature, deposit a substance termed a *stearoptene*, which is analogous to resin. [Camphor.] When a considerable quantity of volatile oil co-exists with a resin, a honey-like consistence is preserved, and the resin is termed *soft-resin*. When a very large portion of oil is present, a fluid condition exists, and *turpentine* is the proper designation.

Resins are the products generally of the most complex and highly organized plants, seldom found in acrogens, except ferns, rarely in endogens, and most abundantly in certain tribes of exogens. They are mostly found in the older and permanent parts of plants, and more copiously the older the individual tree is; nevertheless they are occasionally found in herbaceous plants, and even in the most perishable parts of these. Thus the leaves of the Laretia acaulis (Selinum acaule) secrete resin, forming an exudation, and accumulating into pieces weighing from half to one drachm or more. (Meyen, *Reise*, i., p. 315.) The resins sometimes exude spontaneously; but more commonly they are procured by incisions in the bark. They are fusible at a low temperature, and inflammable, burning with a copious smoke and agreeable perfume; hence their employment as incense or to form pastiles.

Taken internally they are stimulant, promoting secretion of the skin and kidneys; externally, they are rubefacient. Some resins are dangerously caustic, such as euphorbium. The most important medicinal resins have been already treated of. [Boswellia; Elemi; Guaiacum; Mastich; Olibanum.] Several are of great utility in the arts to form varnishes. [Copal; Mastich.] A great variety of vegetable remedies are indebted for their most useful properties to the resin which they contain, in conjunction with other principles, such as jalap, scammony, &c. [Convolvulus.]

RESISTANCE is a power by which motion, or a tendency to motion, in any body is impeded or prevented. When a weight or pressure acts upon a beam or bar in any direction, the tenacity by which the particles of such material oppose that action constitutes a resistance of one kind. [Materials, Strength of.] Again, when a body is made to move on another, the inequalities of the surfaces of both create a resistance of a different kind. [Friction.] When a body moves in a fluid, the inertia of the fluid particles displaced by it produces a third kind of resistance.

This last branch of the subject of resistances has already been in part considered. [Hydrodynamics, p. 393, col. 1.] In that article there is given a general expression for the measure of the resistance made by a fluid against a plane surface which is either perpendicular or inclined to the direction of the motion, together with a few results of experiments on the resistances experienced by bodies of various forms and lengths in moving through water. The relations between spaces and times in the vertical ascent and descent of bodies when acted on by gravity and resisted by a fluid are given in the article Projectiles, Theory of; and, for the pressure against a cannon-ball moving in air, see Gunnery, p. 491, col. 2.

In investigating the resistances of fluids against bodies moving in them, it is customary in elementary writings, for the sake of simplicity, to consider the particles of fluid as unconnected with each other by contact or by any law of attraction, so that, when struck, their reactions may be considered as taking place perpendicularly to the striking surface of the moving body, whatever be the position of this surface with respect to the direction of the body's motion, and after the impact their action is supposed to cease. Such are called discontinuous fluids, and in these the motion produced in the particles by the collision is the measure of the resistance. Newton shows (*Principia*, lib. ii., prop. 35) what would be the resistance experienced by a cylinder moving in the direction of its axis in a discontinuous fluid; the cylinder and particles of fluid being elastic, so that the latter on being struck are reflected back with a velocity double the velocity of the cylinder; and he explains that, if the particles of fluid are not reflected, but are moved forward by the cylinder with a velocity equal to its own, the resistance is but half the former. But this hypothesis is far from being conformable to the constitution of fluid bodies in nature, the particles of these being connected by mutual actions. The elastic fluids, as air, at any place in the atmosphere are always in a state of compression from the weight of the column vertically above that place; and the particles of non-elastic fluids, as water, exert in every direction pressures which depend upon the distances of the particles below the surfaces of the fluid in the vessel, river, or ocean. In passing through a fluid of this kind (called a continuous fluid) a body strikes only the fluid particles which are nearest to it; these strike those beyond, and so on; and Newton proves (lib. ii., prop. 35, schol.) that in this case the resistance to a cylinder is only half the last-mentioned resistance, or one-fourth of the first.

In all these resistances however it is supposed that the particles on being struck are repelled perpendicularly to the front of the moving body; but, in fact, the particles of the fluid are in part repelled from the front in oblique directions, and, on account of the compressed state of the surrounding fluid, these particles not being able immediately to escape laterally, there is produced in front more or less condensation, and consequently an increase of resistance. The pressure of the fluid against the sides of the moving body creates also a resistance from friction; and when the velocity is very great, the fluid not falling towards the hinder part of the body so fast as the latter moves, the pressure there which would serve to counterbalance the resistance in front, is in part or wholly removed. On these accounts it is that military projectiles are subject to such vast retarding forces. It is computed that a 24-pounder ball experiences a resistance equal to 800 lbs. when its velocity is equal to 2000 feet per second. Like effects take place in the movement of boats or ships; when the velocity is great, the water accumulates in front, and flowing off from thence obliquely, it carries away some from the sides, and, causing the surface of that which is near the stern to be rather lower than the general level, it there produces a diminution of pressure, while there is an excess in front on account of the accumulation.

In order to find the pressure of a fluid against a body which is terminated in front by a curve surface, an expression must be obtained (by means of the equation of the surface) for the area of an elementary portion of that surface, and this must be multiplied by the cube of the sine of its inclination to the line of motion. The product being multiplied by $\frac{v^2 D}{2g}$ [HYDRODYNAMICS], and the whole integrated between the proper limits, the result will express the required resistance.

Again, in investigating the motion of a body on an inclined plane when resisted by friction and the pressure of the atmosphere, the general equation of motion $\frac{d^2s}{dt^2} = g - a\frac{ds^2}{dt^2}$ may be employed. Here s is the space described in the time t, $\frac{ds}{dt}$ is the velocity acquired in the same time, and $\frac{d^2s}{dt^2}$ is the differential expression for accelerative or retardative force. If the body were to descend vertically, g, the force of gravity ($= 32{\cdot}17$ feet), would alone be the force producing the motion; and the equation, being integrated, would give the relation between the spaces described and the times of description when the body descends or ascends in a resisting medium. In the first of these cases g should be positive, and in the second negative. In order to adapt the equation to the descent of a body on an inclined plane, let θ be the inclination of the plane to the horizon; then $g \sin. \theta$ would represent the accelerative force on the plane if there were no friction. But since friction is proportional to the pressure ($= g \cos. \theta$) on the plane, and is independent of the velocity, let h be put for the coefficient of friction and represent a fractional part of the pressure; then we shall have $hg \cos. \theta$ for the retardation produced by friction. a is the coefficient of the resistance due to the pressure of the atmosphere; it depends on the form and magnitude of the moving body, and not on its weight; and the resistance is supposed to be proportional to the square of the velocity. Thus the above equation becomes

$$\frac{d^2s}{dt^2} = g \sin. \theta - hg \cos. \theta - a\frac{ds^2}{dt^2};$$

or, since the two first terms of the second member are constant, representing them by A, it becomes $\frac{d^2s}{dt^2} = \text{A} - a\frac{ds^2}{dt^2}$. Integrating this equation by successive approximations, or otherwise, we obtain in terms of t the values of $\frac{ds}{dt}$ (the velocity) and of s (the distance on the plane), either when the body sets out from a state of rest, or when it sets out with any given initial velocity. From these values, by means of the data obtained from good experiments, the values of h and a might be found; and thus the effects of friction might be obtained separately from those which are due to the resistance of the air.

In M. de Pambour's 'Practical Treatise on Locomotive Engines,' there is given, p. 154, an account of some experiments in which a number of waggons, both singly and in trains, were made, by gravity, to run down a double inclined plane; and these, since the motions were not produced by steam or any power which is liable to irregularity, appear to be the most convenient for obtaining the separate values of h and a by means of the above equation. The waggons, or the trains, set out from a state of rest at the summit, and, with the velocity acquired at the foot of the upper plane, they were allowed to run down the second, whose inclination to the horizon was very small (2′ 2″), till, by friction and the resistance of the air, the motion ceased. On making $\frac{ds}{dt} = 0$ and s, equal to the distances given by the experiments on the lower plane, the mean value of h for seven trains of waggons was found to be ·00215, or $\frac{1}{465}$ of the whole weight of a train; and that of a was ·000029. The mean value of h from the equations

$\frac{ds}{dt} (= 0) = \text{A}t + \text{V}$, and $s = \frac{1}{2}\text{A}t^2 + \text{V}t$ (V being the velocity at the top of the lower plane); that is, its value on the supposition that it includes both friction and the resistance of the air, was found to be ·00333, or $\frac{1}{300}$ of the whole weight. Hence the resistance of the air, which is due to the mean velocities, becomes ·00118, or $\frac{1}{847}$ of the whole weight. The mean velocity may be considered as about 12 miles per hour, or 17·6 feet per second.

The above value of h, and this coefficient of the square of the velocity in the term expressing the value of the air's resistance, agree very nearly with those which result from an experiment of Dr. Lardner on the Whiston plane (whose gradient is $\frac{1}{96}$), where the terminal velocity of a train, that is, the uniform velocity acquired when the resistance arising from friction and the air became equal to the force of descent on the plane, was found to be 31½ miles per hour.

The following rule for determining the gross resistance (considering the whole as due to friction) is investigated by De Pambour. 'When a body, from a state of rest, descends down two or more inclined planes till it stops by the effect of friction, the value of the friction is equal to a part of the weight of the body which is expressed by the quotient of the whole height descended vertically, divided by the whole distance passed over on the planes.' The mean resistance found by this rule for the same trains is ·00367 ($\frac{1}{272}$) of the whole weight; and the small discrepancy between this result and that which was found from the two equations above, arises from the resistance of the air being involved in the previous determination of V. It is not supposed however that the absolute values of the terms which have been obtained for the friction and the pressure of the air will serve with precision for trains of a different kind; but, till more extensive experiments have been made, they may have some utility in showing nearly the proportion between those causes of resistance.

The probability, after all, of being able to obtain general formulæ for the resistances experienced by railway trains is at present very small. The best mathematicians have long been foiled in the effort to express analytically the conditions of a very simple body (a cannon ball) moving through the air; and the problem which embraces the ever-varying circumstances attending the motion of a train of carriages is much more complex. The force with which the air acts depends on the form of the leading carriage or engine, upon the condensation of the air in front, and upon its friction along the sides of the carriages. But besides these actions, which it would be difficult to estimate, the air between every two carriages, and even in the interior of open ones, is put in motion, and produces sensible pressures against the fronts, the transverse partitions, and the interiors of the back faces. Winds blowing contrary to the direction of the motion increase the resistance to be overcome; and even those which are oblique or perpendicular to the sides, by pressing the wheels against the rails, add considerably to the friction.

In order to exhibit a comparison of the resistances experienced by a railway train when ascending and when descending an inclined plane, we have taken the first of the examples which have been given in the table in the article RAILWAY. In this the gradient is [illegible], or the inclination of the plane to the horizon is 19′ 25″. The weight of the whole train being estimated at 80 tons, we have 80 × sin. 19′ 25″ = ·452 tons for the moving power of gravity in descending, or the resistance of gravity in ascending; and 80 × cos. 19′ 25″ = 79·999 tons for the constant pressure on the rails. Now the retardation from friction, both in ascending and descending, being estimated at ·00215 of the pressure by the above investigation, we have ·172 tons for the constant resistance on this account. The resistance of the air being found to be ·00115 of the pressure when the velocity is 12 miles per hour, we get ·00412 for the resistance when the velocity is 22·25 miles, and ·01423 when the velocity is 41·32 miles; and these numbers being multiplied by 79·999, give, respectively, ·33 tons and 1·138 tons, for the resistance of the air in ascending and descending.

Then, for the descending motion, subtracting from the sum of the resistances produced by friction and the air the moving-power of gravity, the remainder is 0·858 tons. And for the ascending motion, adding together all the three resistances, the sum is 0·954 tons. The difference is about $\frac{1}{10}$th of a ton, or [illegible]th of the whole weight, and expresses the excess of the resistance experienced by the engine in the ascent above that which it experiences in the descent. If the resistances in the ascent and descent had been computed on the supposition that the motions were affected by gravity and *friction* (taking the latter at [illegible] of the pressure, as if it included the resistance of the air), the former being, as before, = ·452 tons, and the latter ·267 tons; the moving-power in descending would have been ·185 tons, and the resistance in ascending ·719 tons. The difference (which, in this case, is the sum) would have been ·904 tons, or nearly [illegible] of the whole weight. These results will suffice to show that the diminished resistance of the air compensates, in a considerable degree, for the retardation produced by gravity when a train moves on an ascending rail; but numerous and more varied experiments must yet be made before it will be possible to determine how far it would be advantageous to use gradients instead of incurring the expense of making level lines of road.

The method of finding the resistance which an engine opposes in the effort made by the steam to put it in motion, is as follows:—Multiply the area of one of the two equal pistons in square inches by the pressure of the steam on a square inch of the piston in each cylinder, when that pressure is just sufficient to cause the engine to move; the product is the pressure on each piston. Then, since the piston makes two strokes while the wheel of the engine turns once round, the velocity of the piston is to that of the engine as twice the length of the stroke is to the circumference of the wheel; and, the resistances being inversely proportional to the velocities, we have—

circumf. of wheel : twice the length of the stroke ::
pressure on both pistons : the resistance, or inertia,
of the engine.

But the resistance *increases* with the load which the engine has to draw; and, in order to determine it when attached to a train, the above proportion may be used; but the pressure on the pistons, instead of being found as before, must be taken when the engine and train are observed to have a uniform motion. Then the fourth term of the proportion, being diminished by the known resistance of the train, will give the resistance of the engine alone.

From the experiments of Mr. Telford, the following values of the resistances experienced by loaded carriages on level roads have been determined. On a good pavement the resistance is [illegible] of the weight of the carriage and load; on a broken surface of old flint, [illegible]; on gravel, [illegible]; and on a well-constructed railway, from [illegible] to [illegible].

By experiments made on the force (of traction) required to give motion to vessels on canals, it is found that the resistance varies nearly as the cube of the velocity; and this great deviation from the general law of resistances is probably caused by the re-action of the sides of the canal against the water displaced by the vessel. It deserves however to be mentioned, that when the velocity of the vessel is considerable, the resistance has been found in experiment some diminution, perhaps on account of the water momentarily displaced, from its inability to escape laterally, becoming condensed, and thus giving superior buoyancy to the vessel; the immersed part being less, the pressure of the water against the front will also be less.

Mr. Barlow observes that, with small velocities, the force of traction on canals is less than on railways; and when the velocity is equal to four miles per hour, the forces are equal. Beyond that velocity the advantage is in favour of the railway.

RESOLUTION. [SOLUTION.] The resolution and solution of a question are, in common language, the same things. The word is also used as opposed to COMPOSITION.

RESOLUTION, in music, the passing of a discord into a concord. [DISCORD; HARMONY.]

RESPIRATION, or the process of breathing, is that by which changes are effected in the common nutritive fluid of the body by its being brought into contact with the atmospheric air. It is one of the processes by which organic beings are peculiarly distinguished, and is probably carried on in some form by all of them. In the present article it will be considered only with reference to the mode in which it is performed in the animal kingdom, and particularly in man.

The common effect of the respiration of all animals is to remove some of the oxygen from the air which they breathe, and to replace it by carbonic acid gas derived from the blood. When one or more animals are enclosed successively in a vessel containing a given quantity of atmospheric air, the proportion of oxygen in it gradually decreases, till the air is no longer capable of supporting life, and the carbonic acid which is given off from the animal in place of the oxygen acts upon it as a poison. This result has often been obtained by experiments on animals, and is unhappily not unknown in the history of human suffering. In the memorable case of the Black Hole at Fort William in Calcutta, 146 persons were shut up in the evening in a dungeon measuring 18 feet by 14, and having only two small apertures for the admission of fresh air. Of the whole number, only 20 survived till the following morning. These were they who were placed nearest to the apertures; the rest were gradually suffocated by the carbonic acid, which was given off in their respiration more rapidly than the oxygen was renewed by the admission of fresh air.

Oxygen is the only gas by which respiration is supported. It is constantly supplied by the atmospheric air, of whose volume it forms a fifth part, and which is breathed in a free state by mammalia and amphibia, and in solution or mixture in water by fishes and the other truly aquatic animals. Pure oxygen however is not fit for breathing; it destroys life after a few hours, and an animal placed in it dies before it is all replaced by carbonic acid. The nitrogen of the atmosphere dilutes the oxygen to the degree which appears the best suited for respiration; and as the former gas has not its quantity materially altered by being breathed, it is probable that this dilution is the only purpose which it serves in relation to the present function.

There are three chief forms of organs for respiration; *lungs*, which are made up of branched tubes and cells placed within the body; *gills, or branchiæ*, which are vascular processes developed on some part of the exterior of the body; and *tracheæ*, which are tubes that ramify to extreme minuteness, and are dispersed through nearly all the organs of the body. By the first and last of these organs the free air is in almost all cases respired; by the second the air is mixed with water. The essential part of the process of respiration however is the same in all; it will therefore be unnecessary to describe here the varieties of the respiratory organs in different classes of animals, and the more so, as they have been already considered in the general description of each class and of many genera, and since the relation of each kind of organ to the circulatory system in the same class has been pointed out in the article HEART.*

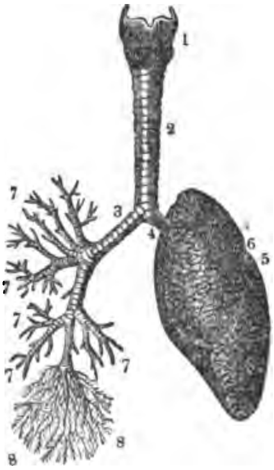
In man, whose lungs may be taken as a type of those of all mammalia, they are thus formed:—The trachea, or windpipe, is a rounded tube continued from the larynx [LARYNX], and commencing about an inch above the upper edge of the breast-bone. Its front and sides are chiefly composed of portions of cartilage forming about three

* It is deemed essential to the comprehension of [illegible] that [illegible] should be read [illegible]. The writer would here also strongly recommend the reader who has not access to the parts of the human body, to examine the parts described here and in [illegible] of the [illegible] in the bodies of some animal, especially the sheep, calf, or pig.

fourths of rings an eighth of an inch wide; and its back part consists of transverse and longitudinal fibres of elastic (and, according to some, muscular) tissue. The rings are connected by tough cellular and elastic tissues, and by numerous strong longitudinal bands; and the whole tube, as well as its farthest ramifications, is lined by a mucous membrane continued from the larynx, and covered on its free surface by a fine epithelium composed of cells with vibrating ciliæ attached to them.

The trachea divides into two main branches, the bronchi, one of which goes to each lung, and in it divides into smaller and smaller branches, whose structure is in all essential respects similar to that of the trachea (*fig.* 1). Around

Fig. 1.



1, the larynx; 2, trachea; 3, right bronchus; 4, left bronchus; 5, left lung, the fissures denoted by the two lines which meet at 6, dividing it into two lobes, and the smaller lines on its surface marking the division of the lobes into lobules; 7, large bronchial tubes; 8, minute bronchial tubes terminating in the air-cells or vesicles.

the extremity of each of the finest branches of the bronchial tubes there are arranged a number of delicate rounded cells or vesicles, all opening into the end of the branch, but having no communication with each other. On the walls of these cells the blood circulates in the minutest capillary divisions of the pulmonary artery and veins, and it is also in these cells that the air, which is admitted to them through the bronchial tubes, comes nearly into contact with the blood. The mode in which the blood is conveyed to the lungs is detailed in the article HEART. The pulmonary artery arising from the right ventricle carries to the lungs all the blood that has been circulating through the body; one main branch goes to each lung, and, accompanying the bronchus, divides, like it, to extreme minuteness. At the last its branches terminate in the capillaries, which are arranged in the most delicate network on the walls of every pulmonary cell. Each of these cells is about $\frac{1}{70}$ of an inch in diameter; the capillary vessels are about $\frac{1}{3000}$ of an inch in diameter; and the network which they form is so close that its meshes are not more than $\frac{1}{3000}$ of an inch wide. In its passage through these the blood undergoes the changes which convert it from venous to arterial, and render it again fit for the maintenance of life. [BLOOD.] From the capillaries it passes into the pulmonary veins, and through them to the left side of the heart.

The lungs are thus mainly composed of air-cells and of branches of the pulmonary artery and veins. Each lung is divided into two or three large portions called lobes (the right lung has almost always three lobes, the left two), each of which receives one of the main divisions of the bronchus, artery, and vein; and these are again divided into lobules, the outlines of some of which are marked by the angular figures on the surface of the lung. Lastly, the cells are grouped together in still smaller lobules not more than a quarter of an inch in diameter.

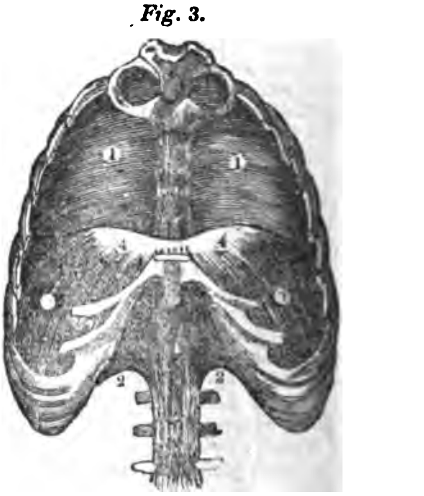
The lungs are placed in the two principal cavities of the chest. The annexed figure (*fig.* 2) represents the bony frame-work of the chest, bounded behind by the spine and the ribs as far outwards as their angles, in front by the sternum, or breast-bone, and the cartilages of the ribs, and on each side by the bodies of the twelve ribs. The space which is left below in the skeleton is, in the entire subject, filled

Fig. 2.

1, spinal column; 2, ribs; 3, cartilages of ribs; 4, sternum.

up by the diaphragm, a large muscle represented in *fig.* 3, whose form may be roughly compared to that of the expanded part of an umbrella having its concavity down-

Fig. 3.

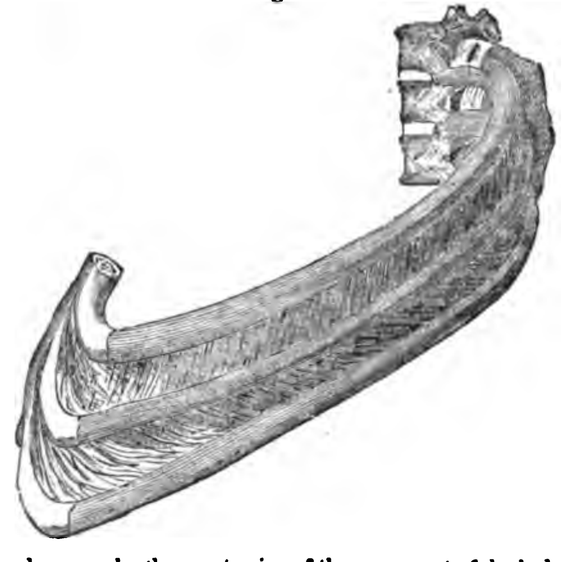


1, cavities of the thorax; 2, portion of cavity of the abdomen; 3, lateral muscular portions of the diaphragm; 4, central or tendinous portion of the diaphragm.

wards. The diaphragm forms a moveable partition between the cavity of the chest and that of the abdomen, permitting only the passage of certain vessels, &c. from the one to the other. By its alternate contractions and relaxations it increases and diminishes the capacity of the chest.

The spaces between the several ribs are filled by the intercostal muscles, of which two are represented in the adjoined figure. Between each two ribs there are two layers of muscle, the fibres of each of which cross those of the other. The fibres of the outer layer, which are represented between the two upper ribs in the annexed figure, pass obliquely from above downwards, and from behind forwards; those of the inner layer, here drawn between the two lower ribs, pass with a similar obliquity from before backwards.

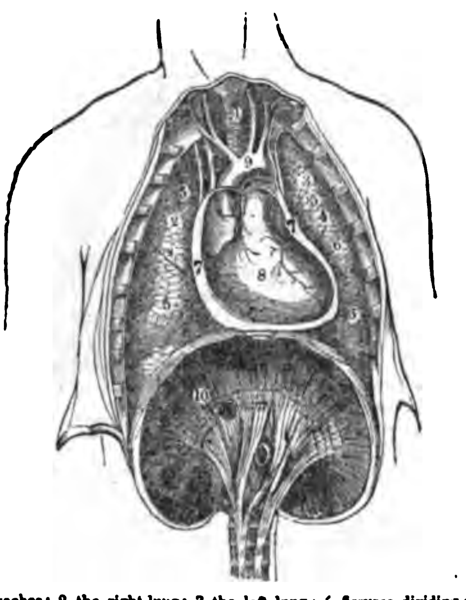
The upper aperture of the chest between the spine, the ribs, und sternum (*fig.* 2) is that at which the trachea passes into the chest to the lungs, and at which the great arteries of the head, neck, and arms pass out of the chest from the aorta. The spaces left between these and the bones are occupied by the œsophagus, by certain muscles, *Fig* 4



and nerves, by the great veins of the upper part of the body, and by cellular tissue.

The whole chest thus forms a cavity closed on all sides, but permitting the passage of certain tubes (the trachea, œsophagus, blood-vessels, &c.) through its walls. This cavity contains within it three subordinate cavities: the middle one contains the heart in the pericardium, and each of the two at the sides contains one of the lungs. These are called the pleural cavities.

Fig. 5.



1, the trachea; 2, the right lung; 3, the left lung; 4, fissures, dividing each lung into, 5, large portions termed lobes· 6, smaller divisions termed lobules; 7, pericardium; 8, heart; 9, aorta; 10, diaphragm separating the cavity of the thorax from that of the abdomen.

Each lung is as it were hung into the cavity appropriated to it by its bronchus and by the trunks of its pulmonary artery and veins, which, enclosed together by cellular tissue, form what is called the root of the lung. The lung exactly fills the cavity in which it is placed, so that their surfaces are everywhere in contact, or separated only by the very small quantity of fluid necessary to keep them sufficiently slippery to move upon each other without difficulty. For the sake of more easy motion, the wall of the cavity is lined and the surface of the lung is covered by a fine smooth membrane, the pleura, which is arranged like other serous membranes [MEMBRANE], that is, having lined the cavity, it is reflected upon the root of the lung, and then passes over its surface and those of its great divisions or lobes.

The pleural cavities are completely closed on all sides, so that no air can enter them, but the lung in each communicates with the external air by its bronchus, which leads to the trachea and larynx; and hence, when the chest is enlarged by the contraction of the diaphragm, the elevation of the ribs, &c., the air passes not into the cavity of the chest, but through the windpipe into the interior of the lung. It is as if one had a pair of bellows with the valve closed, and the tube of the nozzle opening, not as it usually does, into all the space enclosed by the boards and leather, but into a bladder contained within that space. In this case, when the handle of the bellows is raised so as to enlarge the cavity, the air will pass into the bladder, and distend it so as to keep it everywhere in contact with the interior of the cavity containing it.

The acts of breathing are—*inspiration*, by which air is drawn into the lungs, and *expiration*, by which it is again expelled from them. In inspiration the muscles that are attached to and form part of the walls of the chest contract, and by raising the ribs and sternum, and flattening the diaphragm, increase its capacity. The air within the lungs (which are never empty even after the deepest expiration) is thus for the instant rarefied; but by the proportionally increased pressure of the atmosphere upon the upper part of the larynx, a fresh quantity of air immediately passes into the air-tubes, and maintains the equilibrium of pressure between the air within and that without the lungs.

As soon as the action of the muscles of inspiration has ceased, expiration commences; the lungs, distended in inspiration, contract by their own elasticity, and expel a volume of air which, in ordinary circumstances, is equal to that which they had just previously received. As fast as they contract, they are followed by the walls of the chest, which collapse partly by their elasticity, and partly by the pressure of the atmosphere upon their exterior, which, when the lungs begin to contract, is no longer exactly balanced by the pressure exerted through the medium of the lungs upon their interior. The lungs having thus contracted to a certain extent, the parts are restored to the same condition as before inspiration, and in ordinary circumstances that action is soon again commenced.

The enlargement of the cavity of the chest in common inspiration is thus effected: the diaphragm (*fig.* 3, 5) contracts; its muscular fibres, which are attached on the one hand to the interior of the lower ribs, the tip of the sternum, and the front of the spine, and on the other around a tendon (4, *fig.* 3) in its middle, shorten, and thus (as the first set of attachments are fixed) they draw down the middle of the muscle, lessen its convexity towards the chest, make it flatter, and press its under surface upon the contents of the abdomen, so that the abdominal walls become more prominent At the same time, or just previously, the intercostal muscles contract; the two upper ribs, being quite or nearly fixed at one end to the spine, and at the other to the upper part of the sternum (*fig.* 2), serve as fixed points towards which the upper intercostal muscles contracting draw the second ribs; these being thus fixed, the second pair of muscles contract, and draw up the third ribs; and so on through the whole of the ribs, the lowest serving, at the same time that they are drawn upwards, for fixed points, towards which the diaphragm, contracting all round its tendon, may draw down its middle part and become flatter.

The effect of the contraction of the intercostal muscles is not so much to approximate the ribs (which would decrease the capacity of the chest) as to force them further outwards and forwards, and thus give the chest a greater width and depth at each part. In *figs.* 2 and 4, it is seen that the ribs descend obliquely outwards and forwards from the spine, and then ascend towards the sternum. They increase in obliquity as they are taken from above downwards, and, except the four last, they also increase in length in the same succession. The length of the arc represented by each rib from the spine to the sternum is fixed, for the substance of the ribs is bony or cartilaginous, and almost unyielding; when therefore one rib is fixed, and the intercostal muscles between it and the one next below it contract, they must not only draw the latter upwards, but must also turn it somewhat outwards, and raise the sternum, which is fixed to its anterior extremity. The direction of the rib becomes less oblique, but its length remaining the same, the distance from the spine to the moveable sternum must be increased at the same time with the distance from each rib to the corresponding one on the opposite side.

By these actions the cavity of the chest is increased in every direction: in height, by the descent of the diaphragm; in width, by the turning outwards of the ribs; in depth, by the ascent of the sternum. In quiet inspiration the greater part is effected by the diaphragm; in deep inspiration not only are all the muscles already mentioned contracted, but a number of others capable of raising the ribs are called into play, and the capacity of the chest is thus yet further increased in the manner just described.

In their medium state the lungs of a person of ordinary size, and in good health, contain about twelve pints of air; in perfectly easy breathing, about a pint is drawn into them at each inspiration; but from this the quantity may vary to as much as seven pints, according to the force of inspiration, increased as it is, for example, when preparing for a great muscular effort, or during singing, or before coughing.

Quiet expiration does not need any muscular exertion; the elasticity of the lungs, of the cartilages of the ribs, and of the other parts distended in inspiration, is sufficient to restore them all to their previous state. A limit is set to the collapse of the lungs by the unyielding tissues of the walls of the chest. These cannot follow the contracting lungs beyond a certain extent, and the elasticity of the lungs is not sufficient for them to overcome the unbalanced pressure of the atmosphere upon their interior, which it would be necessary for them to do before they could contract from the interior of the walls of the chest. If a wound be made into either pleural cavity, the lung at once collapses completely, and expels nearly all the air it contained; for in this case the atmospheric pressure being admitted alike to the exterior and the interior of the lung, its elasticity has but little to overcome, and the air-cells and tubes immediately contract to the smallest size of which they are capable. By the same means, when both pleural cavities are opened at once, death speedily follows in consequence of the collapse of both lungs and the suspension of all breathing.

The limit which the rigidity of the walls of the chest sets to the elastic collapse of the lungs is never reached in ordinary respiration, nor in extraordinary cases, except by the influence of other expiratory powers besides those of the lungs. These powers are supplied chiefly by the muscles of the abdomen, which contract with great force, and through the medium of the contents of the abdomen force up the diaphragm to an unusual height into the chest, at the same time that certain muscles capable of depressing the ribs and sternum draw them down and decrease the capacity of the chest in its depth and width. Efforts of this kind are observable in coughing, sneezing, and all other strong expiratory acts.

Such are the movements of respiration These however are less important than the chemical changes effected in it, and are even not observed in certain classes of animals, in which the latter are nevertheless constantly carried on. The object of the movements of respiration is the constant renewal of the air in the bronchial tubes and cells. It has been already said that the lungs always (even after the most forcible expiration) contain some air. It is therefore not probable that that which is inspired passes at once to the air-cells, but rather that being drawn into the finer bronchial tubes, it mixes with the air already contained in them, and only gradually arrives at the cells. There is probably a kind of undulation of the volumes of air drawn in and again in part expelled at each complete act of respiration; and we cannot conceive how the air in the cells would be constantly renewed were it not for the tendency of the different kinds of gas to mix according to the laws of diffusion of gases discovered by Dalton, and so fully illustrated by Dr. Graham. The air in the cells contains a large quantity of carbonic acid; that drawn into the tubes in inspiration contains but little of that gas, but one-fifth of oxygen, and thus, independently of the movements of respiration, there must always be a tendency of the carbonic acid towards the atmosphere and of the oxygen towards the air-cells.

With respect to the actual changes in the blood, it was long doubtful whether that fluid contained any gases dissolved in it, and as many of the best chemists failed in their endeavours to extract any, it was commonly supposed that the carbonic acid produced by respiration resulted from the separation of carbon by the blood in the lungs and its immediate union with the oxygen of the air. But to this opinion was opposed the fact, that carbonic acid is given off from the lungs of frogs when they are placed in gases that contain no oxygen, as for example pure hydrogen or nitrogen. Many theories of respiration were therefore proposed, but all failed to explain its phenomena so long as gases could not be found in the blood. Of late years however it has been rendered highly probable, by the experiments of Stevens, Magnus, and others, that the blood does hold gases in solution, which may be separated from it by agitating it with another gas (according to the laws of mixture and displacement of gases dissolved in fluids), or by placing it in nearly an absolute vacuum. The theory of Despretz and Hassenfratz, which had been discarded, is therefore now generally received; and it is believed that the chemical changes of respiration consist essentially in the removal of a portion of the carbonic acid dissolved in the venous blood, and the absorption of an [illegible] or rather larger portion of oxygen from the air; and [illegible] these changes are effected not by any vital act of secretion, but by the tendency to mixture of the different gases, [illegible] is not obstructed by the delicately porous tissues of the air-cells and the capillary vessels.

It appears from the experiments of Magnus (which are in great part confirmed by those of Stevens, Hoffmann, G[illegible], Bertuch, and Bischoff), that the mean quantity of gas contained in the blood is equal to $\frac{1}{10}$ of its whole volume. In venous blood the average quantity of carbonic acid is about $\frac{1}{16}$, that of oxygen about $\frac{1}{33}$, and that of nitrogen about $\frac{1}{1?}$ [illegible] the volume of the blood; in the arterial blood their respective quantities are $\frac{1}{14}$,* $\frac{1}{38}$, and $\frac{1}{72}$. (Müller's *Physiol*[illegible] vol. i., ed. 2.) It follows therefore that the purpose of respiration is chiefly the absorption of oxygen, and [illegible] merely the removal of carbonic acid from the blood; a conclusion which is also rendered probable by the fact that frogs placed in hydrogen or nitrogen die as if suffocated, although as much carbonic acid is given off from their lungs as when they breathe in atmospheric air.

The constant process of respiration effects changes in the blood that are of the first importance to life and health. The watery vapour exhaled from the blood as it passes through the lungs more nearly in contact with the atmosphere than it is at any other part of the system, amounts, according to the experiments of Lavoisier and others, to nearly 8000 grains in 24 hours. The quantity of carbonic acid given off during the same time is estimated to be at the least 14,930 cubic inches, or 8534 grains, containing 2820 grains of carbon; and the quantity of oxygen absorbed amounts in different circumstances to from ¼ to ⅓ more than that of the carbonic acid given out. Nitrogen appears to be in some circumstances exhaled, and in others absorbed, but on this point the results of experiments are at present far from conclusive.

Dr. Prout has shown that the quantity of carbonic acid separated from the blood varies at different periods of the day; it is greatest between 11 A.M. and 1 P.M., and least between ½ past 8 P.M. and ½ past 3 A.M. Its quantity is [illegible] diminished by anxiety and other depressing passions, [illegible] exercise, by strong drinks, or vegetable food; but it is increased when the barometer is low.

The suspension of respiration by any causes produces asphyxia, or suffocation. The oxygen of the blood is essential to the maintenance of the life of the parts in which it circulates, and an excess of carbonic acid in it acts as a poison. It has been already stated that animals die in hydro[illegible] though the carbonic acid is given off; these perish for want of oxygen. Others are destroyed by the excess of carbonic acid; as those who die after breathing the same atmospheric air for some time, but before all its oxygen is consumed, and those who die in an atmosphere containing an abundance of oxygen, but at the same time charged with a [illegible] portion of carbonic acid. The phenomena of asphyxia, [illegible] the peculiar conditions on which it depends, are considered in a separate article. [ASPHYXIA.]

RESPIRATOR, or breath-warmer, an instrument [illegible]cently invented and brought into use by Mr. Julius Je[illegible] for giving warmth to the air drawn into the lungs in b[illegible]ing, and thereby enabling invalids to enjoy the be[illegible] exercise in the open air without injury or inconvenience.

The common practice of wrapping up the lower [illegible] the face in a woollen covering warms the air inhaled th[illegible] it very imperfectly, and in an unwholesome manner, [illegible]ing with it a portion of the impure air exhaled [illegible]

* The fact that in Magnus's experiments the arterial blood [illegible] contain more carbonic acid than the venous, shows that though [illegible] sufficient to establish this explanation of respiration, [illegible] the details [illegible] cess still require to be more carefully examined.

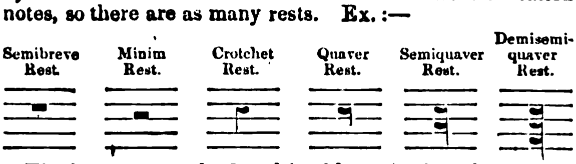
lungs, and detained in its bulky folds. A woollen wrapper, being a non-conductor of heat, can act in no other way. In the respirator this disadvantage is avoided by causing the air discharged from the lungs to pass through several layers of very fine wire, fixed so near together that the breath passing through them is almost infinitely divided, its warmth being abstracted by the metal, which, being an excellent conductor of heat, freely imparts it to the fresh cold air drawn, or, as it were, filtered through it. The compactness of the instrument is such that there is no room for the lodgment of the impure air expelled from the lungs, and consequent contamination of that inhaled; and the condensation of moisture on the wires corrects the injurious dryness of the atmosphere in some northerly winds.

The means by which these objects are attained in the respirator display much ingenuity in contrivance, and no ordinary degree of skill in the execution. The inventor considers it necessary that about twenty layers of metal-work should be used, and, in order to make the instrument as light and compact as possible, each layer is required to be exceedingly thin. The apparatus usually consists of from eight to twelve frames of sheet-silver or other metal, about three inches and a half long, one inch and a half wide, and $\frac{1}{250}$th part of an inch thick; the metal of which is pierced away by machinery so as to leave merely a narrow frame containing six vertical bars of $\frac{1}{30}$th and five horizontal bars $\frac{1}{60}$th of an inch wide. On both sides of each of these frames a layer of wires an inch and a half long and $\frac{1}{450}$th of an inch thick is soldered, care being taken to connect each wire, not only with the top and bottom bars of the frame, but also with each of the five horizontal bars. The wires are laid about $\frac{1}{200}$th part of an inch apart, and are so numerous that a large respirator of high power contains 2000 feet of wire, divided into about 12,000 pieces, and soldered to the frames at more than 80,000 distinct points. The frames or lattices of wire-work, are fixed parallel to each other, and kept a short distance apart by small studs of a substance which is a slow conductor of heat, so that the inner layer is always kept, as nearly as possible, at the temperature of the air expelled from the lungs, and each successive layer diminishes in warmth, till the outer one is nearly as cold as the external air. The curious and philosophical application of a non-conducting medium between the metallic screens is essential to the perfect action of the instrument, as without it the heat would be equally diffused, and no part of the metal-work could retain more than half the temperature of the breath. By this arrangement the air inhaled, finding each layer of wire warmer than the preceding, is gradually raised, in respirators of the highest power, to the greatest attainable temperature. The most powerful respirators have twenty-four layers of wire-work, those of medium power sixteen, and the lowest power eight. The whole of the wire-work is bent into a curved form, and enclosed in a bordering or case of soft leather, which is made to fit closely to the face of the wearer, so as to prevent the entrance of air otherwise than through the metal-work, and to hold the latter in such a position that the lips do not come in contact with the wires. An outer covering of silk or other material is added, having an aperture in which is inserted a very thin plate of silver, perforated with minute holes, and to which a dark colour is imparted by a chemical operation, to serve as a screen to the wire-work, which it hides without impeding the passage of air as most textile fabrics would do. Recently however a very fine and open woollen fabric has been made use of in lieu of the perforated plate, to suit the wishes of some persons to whom the appearance of the instrument was an objection. The common or *oral* respirator covers the mouth only; but a variety called the *orinasal* respirator encloses the nostrils also. A piece of sponge attached to the lower edge of the instrument collects the moisture condensed from the breath, and it, as well as the metal-work and leather mounting, may be detached from the outer covering and cleaned when necessary.

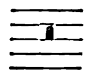
Owing to the complicated and delicate construction of the respirator, for the manufacture of which novel machinery has been required, its price has necessarily been rather high; but some have been lately made of inferior materials at a price within the reach of the poorer classes, in the hope that a very large demand may meet the cost of production. Notwithstanding its recent introduction (the patent having been obtained in 1836), it is already extensively used, and has enabled many who were unable to bear exposure to the severity of an English winter, to face the severest weather with impunity, and even with benefit to their general health; its efficiency having led some patients to designate it a 'portable warm climate.' The orinasal respirator is chiefly used for sleeping in, as it frequently affords relief from distressing night coughs arising from irritation of the air-passages, and enables patients to enjoy undisturbed rest. In addition to the comfort afforded by it, the respirator is expected to prove a preventive of diseases of the lungs; and it has been found beneficial by some for indoor use, because, by economising the animal heat, it promotes a genial warmth in the limbs. It should be stated that the respirator occasions no obstruction to the voice.

RESPONDE'NTIA. [BOTTOMRY.]

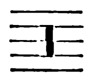
REST, in music, a character denoting silence; a cessation of sound equal in duration to the note represented by the *rest*. As there are six musical characters called notes, so there are as many rests. Ex.:—



The breve rest, to be found in old music, is a short thick bar connecting two lines. Ex.:—



In separate vocal and instrumental parts, a character uniting three lines, and indicating a rest four bars in duration, is employed. Ex.:—



The following is the manner of directing a silence, or rest, of eleven bars, in any of the modern times or measures:—

RESTIA'CEÆ, a natural order of plants, principally inhabiting the southern hemisphere, and nearly related to the Cyperaceous order of Europe. They abound at the Cape of Good Hope and in New Holland, where they form a hard, wiry, rushlike herbage. They have in general a scaly, creeping, rhizoma, or root-stock, simple stems clothed with the sheaths of abortive leaves, and glumaceous flowers with a tolerably regular structure. The floral envelopes generally consist of 4 or 6 glumes in two rows. The stamens are two or three; the ovary for the most part 2-3-celled, with a single ovule in each cell. The fruit is either a nut or a

Restio tetraphyllus.

1, the male; *a*, the stamens and abortive ovary: *b*, the same enclosed within the floral envelopes. 2, The female; *c*, the flower; *d*, the ovary with abortive stamens; *e*, a section of the ripe seed, showing the embryo.

3-celled seed-vessel; the seeds are pendulous, and the embryo is a small lenticular body lying within albumen at the end of the seed most remote from the hilum. In almost all cases the sexes are separate. The hard texture of some species renders them suited for thatch for houses, but they are of no other use.

RESTITUTION (in Law) *of lands*. Where a forcible entry or detainer of lands is on inquiry duly found, or after conviction under an indictment for a forcible entry, the court before whom the inquiry is made, shall cause *restitution* of the lands to be made to the party who has been turned out of possession. (Com., *Dig.*, 'Forceable Entry,' D 5, &c.)

Restitution of stolen goods. By 7 and 8 G. IV., c. 29, s. 57, if any person guilty of a felony or misdemeanor under that act, in stealing, converting, or receiving any property, shall be indicted for such offence by the owner or his executor, and convicted, the property shall be restored to the owner, and the court before whom the person shall be convicted shall have power to award writs of restitution for the property, or order it to be restored in a summary manner. Provided that if it shall appear that any valuable security shall have been *bonâ fide* paid or discharged by some person liable to pay it, or being a negotiable instrument shall have been *bonâ fide* taken or received by transfer or delivery by some person for a valuable consideration, without any reasonable ground to suspect that it had been stolen, &c., then the court shall not order the restitution of such security.

Before this act, the owner was in all cases entitled to restitution on conviction for a felony, but not for a misdemeanor. During the period between the theft and the conviction, or acquittal or death of the prisoner, the ownership of the property is suspended. (2 *Inst.*, 711; Horwood v. Smith, 2 *T. R.*, 750; Burn's *Justice*, 'Restitution.')

Restitution also formerly took place where the heir of one attainted of treason was relieved from the consequences of the attainder. (3 *Inst.* 'Restitution.')

RESTORATIONS, in Architecture, a term applied to drawings intended to show antient buildings according to their original design, as made out from their existing remains, aided by such descriptions or hints as are to be obtained from classic authors, or from the representations of them on coins. In some cases the building itself will afford sufficient data for a complete restoration of it upon paper; but in others, considerable research and study are requisite, and, after all, the restoration will be chiefly conjectural. Even the best preserved architectural monuments of antiquity are in fact only comparatively entire, and are more familiar to the student in their restored than in their actual form; for many of them present only masses of ruins, which it would be a work of time and study to investigate without the assistance of the drawings of those who have already done so. For our knowledge of some edifices we are now entirely indebted to the labours of those who had made drawings of them both in their actual state and in what they have supposed to be their original one, even the remains of them having disappeared since their time. Restorations are frequently also very necessary in order to give an accurate idea of buildings which, although still entire, have been greatly altered and disfigured by having been adapted to other uses—by modern additions or spoliations. Such is the case with the Pantheon at Rome, which now presents little more than the mere carcass of the antient structure, having been stripped of all its bronze work and sculpture, and modernised in its interior with much that is in a very inferior taste, to say nothing of the two belfries that form such barbarous excrescences to the exterior. [PANTHEON.] This edifice has accordingly been frequently made the subject of *restorations*. Zahn and others have made some interesting restorations of private mansions at Pompeii, for which there exist tolerably sufficient if not complete data, both as regards the buildings themselves and their interior decorations, besides various articles of their furniture. But there are many things in regard to which it is now hopeless to look for satisfactory evidence in any remains of antient structures; and among them is the *scena* or stage of a Greek or Roman theatre, relative to which very little that can be safely depended upon is now known: nothing more in fact than a few of the permanent decorations, which of course do not go far towards elucidating the entire arrangement and construction of that part of such edifices; consequently we are quite at a loss to understand what was their stage apparatus, and what were the contrivances resorted to for the machinery which was occasionally requisite. Besides the changes which buildings themselves have undergone, either through decay or from accidental causes, there are others which are hardly considered as belonging to the province of architectural restorations, namely, those of *locality*, by which term we understand not the mere situation, but all the surrounding objects—the entire scene or view, of which the edifice now remaining was the principal feature. Thus, though we can form a tolerably exact idea of the Parthenon, and also of the other buildings on the Acropolis, and are at no loss as to their relative situation, all the rest is a mere blank, which we are now wholly unable to fill up so as to complete the entire scene with all its details, and which therefore may be compared to a picture from which all but the heads of the figures have been effaced.

RESULTING USE. [USE.]

RESUSCITATION (from *resuscito*, to arouse, to revive), the restoring to animation of persons apparently dead. Under this term, strictly speaking, should be considered the restoration of all cases of suspended animation, whether arising from disease or as a result of asphyxia, yet it is chiefly made use of to designate the recovery of persons from this latter condition. The symptoms, physiological conditions, and causes of asphyxia are fully described under that head; the treatment of it generally, and of its different varieties, was reserved for the present article. Although the suspension of all the vital actions of the system which takes place in asphyxia has originated from the temporary interruption of a single function, yet the derangement which has followed is of so complicated a nature, and extends to so great a number of important organs, that the mere re-establishment of the function primarily disturbed is not immediately followed by the restoration of the rest, and by the removal of all the mischief. The mere introduction of fresh air into the lungs cannot at once restore the action of the heart, or of the diaphragm, and of the other muscles which are concerned in respiration, because these muscles have lost either the whole or the greater part of their irritability, in consequence of having been supplied with venous instead of arterial blood. While the first and principal object is to bring the blood contained in the pulmonary vessels under the influence of atmospheric air, attention must at the same time be paid to the state of the circulation, and to the restoration of those powers by which that function, as well as respiration, is to be carried on. The first of these objects can be accomplished by the artificial inflation of the lungs; the second is to be attempted by the judicious application of stimulants to various parts of the body. The details of these processes have been already given in the article DROWNING. But asphyxia may also occur from the presence of foreign bodies in the larynx, which mechanically prevent the inflation of the lungs through the natural passage; in this case the operation of tracheotomy must be resorted to, and the pipe of the bellows must be introduced into the windpipe through the opening thus artificially made. In addition to the employment of artificial respiration, and the use of external and internal stimulants, many physicians have recommended blood-letting; but besides the doubtful advantage which sometimes may accrue from this practice, it is not always possible, and such is especially the case if the asphyxia is of long continuance. In general, the effects of blood-letting would be injurious, and it is now rarely had recourse to unless there are very unequivocal indications of great pressure on the brain. Whatever may be the means that we employ, they should be persevered in till the signs of death are no longer equivocal. Dr. Currie, in his 'Observations on Apparent Death,' recommends their being persisted in for at least six hours; the French writers mention the commencement of rigidity of the limbs as the only criterion of the hopelessness of continuing our efforts. The first signs of returning animation are slight convulsive twitchings in the muscles of respiration, which give rise to gaspings and sighings. By degrees these spontaneous efforts become more regular, and natural respiration is restored; and together with it the circulation returns. The first return to sensation is usually attended with great suffering, and the utmost attention is required to guard against the dangerous symptoms which sometimes show themselves at this period, in illustration of which we may quote the following case, mentioned by Dr. Paris:—A corporal of the Guards was seized with cramp as he was bathing in the Thames, and remained for several minutes under water. By judicious assistance however he was recovered, and appeared to those about him to be free from any danger, when he was attacked with convulsions, and expired. Had the respiration been artificially supported at this period, so as to have maintained the action of the heart until the black blood had returned from the brain, it is probable that the life of the soldier might have been preserved.

Treatment of particular kinds of Asphyxia.—This is to be conducted upon the general principles before explained, which must be varied only according to the particular condition of the body at the time. If the temperature is much below the natural standard, as after immersion in water, the application of heat must by no means be neglected. On the contrary, should the temperature of the body be at or above its natural standard, no more powerful excitant can be used than cold water; hence the dogs which are made the subject of experiment at the Grotto del Cane are usually plunged into a neighbouring lake after exposure to the mephitic gas, as a means of hastening their recovery. It is in the treatment of persons apparently dead from hanging, or other modes of strangulation, that a small quantity of blood drawn from the jugular vein is useful in unloading the vessels of the brain; but the depletion must be merely sufficient to effect this object, and must not be carried to the extent of weakening the powers of life.

RETAINER. [Executor; Serjeant-at-law.]

RETARDATION. [Acceleration.]

RETE'PORA. [Polypiaria.]

RETFORD, EAST, a borough in the North Clay division of the wapentake or hundred of Bassetlaw, in the county of Nottingham, in England, 128 miles in a direct line north-north-west of the General Post-Office, London, or 142½ miles by the Edinburgh and York mail-road through Ware, Huntingdon, Stamford, Grantham, and Newark; in 53° 19′ N. lat. and 0° 56′ W. long.

East Retford stands on the right or east bank of the river Idle, a feeder of the Trent. The area of the borough and parish (for the two are coincident) comprehends only 130 acres (the greater part of which is built over), but the town extends into the adjacent parishes of Clareborough and Ordsall: and the village of West Retford, which is on the opposite side of the river, and is connected with East Retford by a bridge, may be regarded as a portion of it. The borough had, in 1831, 507 houses, inhabited by 525 families; 38 houses uninhabited, and 1 building: the population was 2491, scarcely any part of it agricultural: Clareborough (one of the parishes forming the liberty of Southwell and Scrooby) had an area of 3870 acres; 477 houses, inhabited by 501 families, 28 houses uninhabited, and 2 building, with a population of 2106, about one-fourth agricultural: Ordsall (in the Hatfield division of Bassetlaw wapentake) had an area of 1930 acres; 186 houses, inhabited by 190 families, 14 uninhabited, and 5 building, with a population of 809, about two-thirds agricultural: and West Retford (in the same division) an area of 1080 acres; 150 houses, inhabited by 152 families; and 2 houses uninhabited, with a population of 593, about one-fifth agricultural: making a total of 7110 acres; 1320 houses, inhabited by 1368 families; and a gross population of 5999.

The town thus composed consists of several streets, the principal of them converging not far from the head of the bridge on the East Retford side. The streets (in the borough at least) are well paved, and lighted with gas. The houses both in East and West Retford are very good. The chief extension of the town of late years has been on the south side of the borough, in the suburb of South Retford, in Ordsall parish. The church of East Retford, dedicated to St. Swithin, is large and handsome, with a lofty square tower: it is of various dates, and exhibits the different styles of Gothic architecture. It was antiently larger, but portions of it have been pulled down. West Retford Church is small, with a tower and an elegant crocketed spire. Clareborough and Ordsall churches are both remote from the town; but in the suburb of Moorgate, in Clareborough parish, a chapel-of-ease has been built in the later Gothic style. There are several dissenting places of worship. The town-hall is a neat and commodious building: there are a theatre, a news-room, a free-school, and one or two ranges of almshouses. There is scarcely any kind of manufacture carried on, the business of the town being a retail trade for the supply of the surrounding agricultural district. Formerly there was a good deal of malting; afterwards the manufacture of hats was introduced; and the late Major Cartwright established a worsted-mill, which gave employment at one time to 600 people, but ultimately failed. The market is on Saturday, and is in autumn well supplied with hops, of which many are grown hereabout: there are two yearly fairs; and one great market for horses, black cattle, cheese, and hops. The river Idle is not navigable at this part of its course; but the Chesterfield Canal passes close to the town, and opens a communication with the Trent.

The borough is said to be a borough by prescription: various charters have been granted by Henry III. and succeeding sovereigns. At the time of the Report on Municipal Corporations, petty-sessions weekly and quarter-sessions for the borough were held. The Court of Record had fallen into disuse. The corporation, under the Municipal Reform Act, consists of 4 aldermen and 12 councillors, and the town is not to have a commission of the peace, except on petition and grant.

This borough sent members to parliament, 9 Edward II.; but for a long time after that period, its right was suspended or disused. In 13 Elizabeth it returned members again, and has done so ever since; but in consequence of a parliamentary inquiry into the corruption practised at the election in 1826, the suffrage was extended to the freeholders of the hundred of Bassetlaw. The number of voters on the register in 1834-5 was 2459; in 1835-6, 2835.

The living of East Retford is a vicarage, of the clear yearly value of 140*l.*, with a glebe-house; that of West Retford is a rectory, of the clear yearly value of 364*l.*, with a glebe-house.

There were in the borough, in 1833, eleven day-schools (one of them an endowed grammar-school), with 293 scholars; and two Sunday-schools, with 377 children. The three parishes of West Retford, Clareborough, and Ordsall contained one boarding-school, with from 12 to 14 scholars; twelve day-schools, with 240 or 250 scholars; and six Sunday-schools, with about 609 children. The grammar-school, though wealthy, was comparatively inefficient, through abuse and consequent litigation.

RETHEL, a town in France, capital of an arrondissement in the department of Ardennes, on the north or right bank of the Aisne, 117 miles from Paris by the road through Soissons and Reims, and 27 miles from Mézières, the capital of the department.

This town is supposed to have been built on the site of a Roman fort. In the middle ages it was under its own counts, and was made, in 1581, the seat of a duchy conferred by Henri III. on Charles de Gonzague, duke of Nevers, whose descendants sold it to Cardinal Mazarin. It was taken by the Spaniards, A.D. 1650 and 1655; the second time it was retaken by Turenne. Its territory was called Le Rethelais. The town stands on a hill sloping down to the river, over which there is a wooden bridge communicating with the suburb of Les Minimes, on the opposite bank of the river. There are three other suburbs; and the town is entered by three old gates. The streets are tolerably wide and well laid out, but steep; the houses, usually of two stories above the ground, are of wood, and rather meanly built. There are two large squares or places; one of them, the market-place, is large, and has a good market-house. There are two parish churches, and two other churches or chapels. The church of St. Nicholas has a tolerably handsome steeple.

The population of the commune, in 1826, was 6147; in 1831, 6585; and in 1836, 6771. It is a busy little place; woollen yarn is spun, and as water is employed as the moving-power, two small streams which flow into the Aisne are turned to good account in this way: cachemires, woollen cloths, kerseymeres, flannels, merinos, and other woollens are woven. There are tan-yards and curriers' shops, breweries, and iron-forges. Considerable trade is carried on by means of the canal of Ardennes, which opens or will open a communication between the Meuse and the Aisne. The neighbourhood of the town is fertile, yielding timber and pasturage, and containing stone-quarries and iron-mines. There are six fairs in the year.

Rethel has a high school, an agricultural society, an hospital, an asylum for old people and foundlings, two prisons, and a theatre. There is an agreeable promenade on the banks of the river planted with elms.

The arrondissement of Rethel contains 124 communes it is divided into six cantons or districts, each under a justice of the peace: the population, in 1831, was 65,845.

RETI'CULUS, or RETICULUM RHOMBOIDA'LE (the rhomboidal network formerly used to divide the field of a telescope), a southern constellation of Lacaille, situated directly between the great stars of Argo and Eridanus.

RETI'FERA, M. de Blainville's first family of his order *Cervicobranchiata*. [CERVICOBRANCHIATA.]

RE'TINA. [EYE.]

RETINASPHALTUM occurs in irregular opaque masses of a pale brownish-yellow colour, having a glistening lustre and imperfect conchoidal fracture. It is soft and brittle, melts when placed on hot iron, smokes, and afterwards burns with a bright flame, emitting a fragrant odour. Partly soluble in alcohol, leaving an unctuous residue. It is more nearly allied to bitumen than any other substance. Specific gravity 1·1 to 1·2.

That found near Bovey Tracey in Devonshire has a dry earthy texture; that from Wolchow in Moravia is hard and resinous. According to Hatchett, it contains—

Resin soluble in alcohol	55
Insoluble bituminous matter	41
Earthy matter	4
	100

RETORT, a chemical vessel in which distillation or decomposition is effected by the application of heat; for different purposes retorts are made of glass, earthenware, and metal.

Glass retorts are usually of the annexed form, with a receiver attached; they may be employed for the preparation of such products as do not require any extraordinary degree of cold for the condensation of their vapour: such a liquid is nitric acid. In this cut *a* represents the body of the retort, *b* the neck, and *c* is the receiver, secured to the retort by means of lute. To prepare this acid, nitrate of

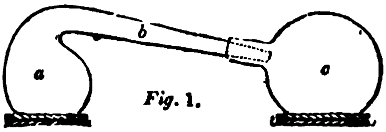

Fig. 1.

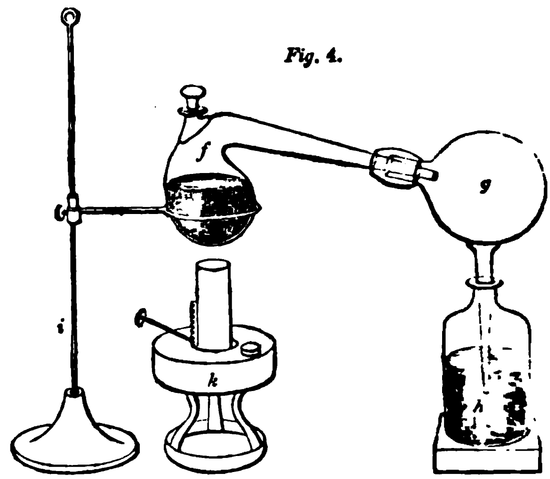
Fig. 2.

Fig. 3.

potash is carefully conveyed by the neck into the body of the retort, and then sulphuric acid is added to it by means of the retort funnel *d*, which prevents any of this acid from remaining in the neck of the retort, and being washed down by and contaminating the nitric acid, as it condenses and passes into the receiver. In this case, when heat is applied to the retort, nitric acid and water rise together in vapour from the body of the retort, and are condensed in the neck; but when the product is more difficult of condensation, the neck of the retort is lengthened by placing an adapter *e* between it and the receiver, to both of which it is secured by lute; it being understood that the wider end slips over the aperture of the retort, and the narrower one is admitted into the mouth of the receiver. In some cases condensation is accelerated by causing a small continuous stream of water to fall on the neck of the retort.

A stoppered retort *f* is sometimes used instead of a plain one; these retorts are more expensive, but much more convenient than common ones; for both the dry and the liquid substances to be employed in the operation are passed into the body of the retort through the aperture, which is afterwards secured by a stopper, without having recourse to the retort funnel. Frequently also a quilled or tubulated receiver is used instead of the plain one above described: this is represented by *g*; the tube is inserted into a bottle *h*, and this, when ammonia or other very volatile or difficultly condensible products are distilled, dips into water, or the receiving-bottle itself is immersed in water kept cold by ice or by a freezing mixture, as when hydrocyanic acid is distilled: *i* is the stand which supports the retort, and *k* is the lamp by which heat is applied to it.

Fig. 4.



Glass retorts and receivers are made of various sizes, capable of containing from a few ounces to several gallons, and both flint and green glass are used in their manufacture. Usually, instead of applying heat by a lamp, retorts are heated in a sand-bath, and sometimes they are subjected to the direct action of the fire; but before this they are usually commonly protected by a coating of lute. [LUTE.]

In general, when the application of the higher temperatures is required for distillation or decomposition, earthen retorts are employed. In preparing hydrofluoric acid, lead is used; and in concentrating sulphuric acid, platina retorts are now largely employed, and would be universally so, were it not for their very high price.

In the destructive distillation of coal [GAS LIGHTING], iron retorts are used, and also, on the small scale, for obtaining oxygen from the peroxide of manganese, and various other chemical operations.

RETRENCHMENT, in Fortification, is a work constructed within another, in order to prolong the defence of the latter by impeding or preventing the formation of lodgments when the enemy has gained possession of *it*; or to afford protection to the defenders till they can retreat with safety or obtain a capitulation. In the latter respects the interior work is called by the French engineers a *reduit*.

Every principal work in permanent fortification is provided with its retrenchment or reduit; and some of these, as the reduit of the ravelin, and of the re-entering places of arms, are constructed at the same time as the work itself, while others, as the retrenchments within a bastion, are generally executed but a short time before they are wanted.

In 1552, when Metz was besieged by Charles V., the Duke of Guise, who commanded in the town, by constructing new ramparts within the old, as fast as the latter were destroyed by the besiegers, succeeded at length in compelling the emperor to raise the siege; and at the siege of Candia (1666-1669), the Venetians raised a rampart from one curtain to the next in rear of the gorge of the bastion St. Andrea, so that, long after that bastion was breached and taken, the town continued to hold out. Such prolonged defences are now rare, and the governor of a fortress is considered as having fulfilled his duty if he do not surrender till a breach has been made in the rampart of the enceinte; though if the bastion were retrenched, he might sustain an assault without any risk of being refused a capitulation, or of seeing the town given up to be plundered.

In the event of the assailants gaining the top of the breach, the defendants would be able to retreat within the retrenchment, the fire from which might then be concentrated upon the enemy while confined within the comparatively narrow space between the faces of the bastion.

The kind of retrenchment proposed by Cormontaigne for the bastion of a fortress is a rampart or parapet extending across the interior of the work in a right line, or rather in the form of a tenaille. [X, FORTIFICATION, vol. x., p. 377.] Its extremities join the faces of the bastion at 20 or 30 yards in front of the shoulders, by which means the flank is left quite free, so that all its artillery can be employed in the defence of the main ditch, and there is room between the retrenchment and the shoulder of the bastion for two guns, by which the interior of the ravelin and the ditch of its reduit might be defended, if necessary, even after the enemy had made a lodgment in the bastion.

As the retrenchment in this situation is liable to be enfiladed by a battery of the besiegers on the glacis before the collateral bastion, it is proposed that another should be formed in rear of the gorge of the bastion attacked; and as in this case there would be sufficient room, the retrenchment may be in the form of a front of fortification with a revetted scarp and counterscarp.

The ditch in front of a retrenchment, as at X [FORTIFICATION], is cut quite through the parapet of the bastion, in order to prevent the enemy, after the assault at the breach, from passing along the top of that parapet, and getting to the rear of the retrenchment. This opening of the parapet does not however go lower than the level of the cordon of the scarp revetment, in order to avoid diminishing the height of that scarp, and thus offering a facility to the enemy, should he attempt to escalade the work at that place.

Cormontaigne proposed to retrench small bastions by constructing within them cavaliers of the same form as the bastion itself, and having a command of 5 or 6 feet above it. The fire from this high parapet might give the work some advantages during the progress of the siege; but from its figure a cavalier appears to be less proper than a retrenchment in the form of a tenaille, for the defense of the terreplein at the top of the breach.

It is evident that full bastions like A [FORTIFICATION] must be more convenient for being retrenched than those which are of the kind called hollow, as B; since less earth is wanted to raise the retrenchment to the required level, and the scarps are covered by the opposite side of the ditch from the view of the enemy at the top of the breach. The most simple manner of retrenching a hollow bastion would be that of retaining the rampart on the interior side, where it is usually 10 or 12 feet high, by a wall, and cutting a deep ditch at the foot; then forming a traverse across the terreplein of the rampart on each face (at 20 or 30 yards from the salient angle of the bastion) with a ditch in front. The enemy, in gaining the top of the breach, would then find himself arrested by these obstacles, and exposed to the fire of the defenders, till ladders and the support of a large body of troops could be obtained. The bastions of Ciudad Rodrigo, Badajos, and St. Sebastian were retrenched in this manner when those fortresses were besieged by the British and their allies during the Peninsular war.

Vauban, having observed that the ravelin was sometimes abandoned by the defenders previously to an expected assault, on account of the difficulty of retreating across the main ditch under a fire from batteries on the glacis before the bastions, constructed, in the interior of that work, another, which might afford the defenders protection till the coming night would permit them to retire in safety. This work was at first only a wall, pierced with loop-holes for musketry and covering the steps at the gorge; but when Vauban increased the size of the ravelin, he made this redoubt, or retrenchment, to consist of a rampart and parapet similar to those of the ravelin itself, as at Neuf Brisac; and Cormontaigne subsequently enlarged the work, so as to render it a second ravelin, as at Y [FORTIFICATION]. This spacious retrenchment contributes much to the prolongation of the defence of the ravelin, since it is capable of containing a large body of troops; and each of its flanks can carry three guns, whose fire might be directed against the counter-battery at the salient of the bastion, or might serve for the defence of the breach in the face of the latter, should the enemy attempt to make an assault before he has obtained possession of the reduit. But to take this last, it would be necessary to breach its faces either by artillery or by mining; and the passage of its ditches would be difficult under a close fire from the ramparts near the shoulders of the neighbouring bastions.

In order that the defenders might be able to retain possession of the extremities of the ravelin, near the main ditch, after the salient part may have been taken, retrenchments, or conpures, as they are called, similar to the traverses, *t, t*, &c., are recommended to be formed across the terreplein of the ravelin. Behind these some of the defenders may retire, and keep up a fire against the enemy's lodgment near Z.

When Vauban had enlarged the re-entering places of arms, L [BASTION; FORTIFICATION], he retrenched the interior with stockades, which, by covering the steps leading from the ditches in their rear, protected the retreat of the defenders of the covered-way; and Coehorn appears, about the same time, to have constructed brick walls, provided with loop-holes, in the places of arms, at Bergen-op-Zoom, for the same purpose. But Cormontaigne, in order to render the defence of the places of arms more obstinate, and to secure more effectually the retreat of the defenders of the covered-way, constructed reduits, as W [FORTIFICATION], with parapets of earth 12 or 14 feet thick; and he revetted the sides of their ditches, in order to diminish the risk of a surprise: he also gave them flanks, which he made perpendicular to the covered-way, that a fire of light artillery or musketry might be directed from them against the enemy while attempting to crown the salients of the ravelin. These reduits moreover cover the shoulders of the bastions and the portions of the curtain which might be seen and breached by a fire directed between the flanks of the bastions and the tenailles; and their faces are directed so that they cannot be enfiladed. The crest of their parapet is about four feet higher than that of the glacis in their front.

The advanced works about a fortress are recommended to be retrenched with round-towers of masonry, provided with upper and lower tiers of loop-holes for musketry. These are called *safety redoubts;* and in Montalembert's 'Fortification Perpendiculaire,' such towers are constructed, to carry artillery, within the rampart of the enceinte.

For retrenchments in field fortification, see BLOCKHOUSE.

RETROGRADE, moving backwards, as opposed to DIRECT. In astronomy all motion from east to west is retrograde: thus the apparent motion of the heavens is retrograde, and the earth's diurnal motion, which causes it, is direct.

RETURN OF CATTLE, &c. is a term applied to the restoration of cattle, &c. distrained, to the party by whom they were distrained, after it has been ascertained that the distress was rightfully taken. The restoration of the cattle, &c. distrained to the owner is not called a return, but a replevin. [REPLEVIN.]

RETURN OF WRITS. When process [PROCESS] issues, the party to whom it is directed is commonly required to do a specified act, to certify the court in what manner the command has been executed, and at the same time to produce or *return* the process itself. Hence the whole answer to the process is called the return. In most cases, this is a duty performed by the sheriff. [SHERIFF.]

RETZ. [LOIRE INFERIEURE.]

RETZ (JEAN FRANÇOIS PAUL DE GONDI), CARDINAL DE, descended of a rich and powerful house, was born in October, 1614. Destined by his father to the church, in the hope of his obtaining the archbishopric of Paris, then held in succession by two members of his family, he was compelled to enter upon a profession repugnant and unsuitable to his ardent, unscrupulous, and intriguing temper. His youth was sullied by debauchery, while at the same time his theological studies were prosecuted with success and distinction; but in the history of the contests of parties in Greece and Rome, he found a more congenial pursuit, and brilliant and seductive examples of what he most coveted, political ability and success. His first political connection was with the Comte de Soissons, to the success of whose revolt he looked forward for the means of abandoning his profession. Disappointed by the death of that nobleman, he resumed with more regularity his ecclesiastical studies and employments; and gained the good opinion not only of the clergy of Paris, but of Louis XIII., who, on his death-bed (1643), named Gondi coadjutor to his uncle the archbishop of Paris. He devoted himself zealously to discharge the external functions of his office; and by this regularity, and by his profuse distribution of alms, established his popularity with the citizens. The bent of his mind however is shown by his answer to one who reproached him with prodigality: 'Cæsar, at my age, owed six times as much as I.' His conduct made him an object of suspicion to the court; and though on the first breaking out of the disturbances of the Fronde he rendered active and valuable assistance to the royal cause, still his sincerity was not credited; and he was driven by the distrust of the court, co-operating with his own ambition, to become, not indeed the avowed leader, but the moving spirit of the popular party. 'Before noon to-morrow,' he said, when his resolution was formed, 'I will be master of Paris:' and he kept his word. This was the eminence to which the dreams and studies of his youth had led him to aspire. 'I am convinced,' he says in his Memoirs, 'that it requires greater qualities to be a good party leader, than to be emperor of the universe.' Throughout the wars of the Fronde, a busy period of domestic contest, he maintained his ascendency [FRONDE]; and he has earned from one of his biographers the praise of being the only person who in those troubles sought not gain, but reputation. The praise of generosity towards his bitterest personal enemies is also due to him. The war was closed by the return of the court to Paris, in October, 1652. Tempting offers were made to induce Gondi, who had now risen to the rank of cardinal, to quit his see and repair to Rome, with the title of ambassador; but while he hesitated, and sought to make terms for his friends, he was arrested, Dec. 19, without resistance on the part of the Parisians, who, by this time, were well wearied of civil war. For some time he was very closely confined at Vincennes. By resigning his archbishopric however, to which he had now succeeded by the death of his uncle, he purchased his removal to the château of Nantes, from which he effected his escape into Spain (1654), with singular boldness and good fortune. From Spain he repaired to Rome, where, in spite of the opposition of the cardinals attached to France, he supported the consideration due to his talents, and, it is said, decided the election of Pope Alexander VII. Having revoked his resignation, he maintained during some time his vicars in the administration of the archbishopric; and at last, by its surrender in exchange for other benefices, after leading for some years a wandering life, he effected his reconciliation with Louis XIV., and his restoration to France. The remainder of his life was spent chiefly in retirement, in works of charity and piety. He sold his estates, and, reserving a sum sufficient for his maintenance, devoted the bulk of his revenues to the payment of his debts; which he thus liquidated, to the great amount, as it is calculated, of more than four millions of francs, modern money. Mad. de Sévigné, who was intimate with him during his latter years, speaks with enthusiasm of the charms of his conversation, the elevation of his character, and his mild and peaceable virtues. We must conclude therefore that reflection and adverse fortune had worked a great and salutary change in his disposition. He died at Paris, Aug. 24, 1679.

His political writings, being chiefly of the nature of pamphlets, are forgotten: as an author, his reputation rests on his Memoirs, written, Voltaire says, with an air of grandeur, an impetuosity and inequality of genius, which are the picture of his conduct. The memoirs of Joli, the cardinal's secretary, also contain copious materials for the biography of De Retz.

The following character of De Retz is from the pen of his political adversary the celebrated Duc de la Rochefoucauld:—'Paul de Gondi has great elevation of spirit, and more ostentation than real greatness of courage . . . He appears ambitious, without being so: vanity has prompted him to great attempts, almost all of them at variance with his profession. He has raised the greatest troubles in the state, without any regular plan of profiting by them; and far from declaring himself the enemy of Mazarin, to occupy his place, his only object has been to appear formidable to him, and to please himself by the false vanity of being in opposition to him. He has borne his imprisonment firmly, and has gained his liberty by his own boldness alone. . . . He has taken part in several conclaves, and his conduct has always increased his reputation. His natural turn is to indolence: he labours with great activity in the matters which press on him, and reposes carelessly when they are finished. That which has most contributed to his reputation, is the knowledge how to set his faults in the best light.'

REUCHLIN, JOHN, an eminent German scholar, was born in 1455, at Pforzheim, in the dominions of the margrave of Baden. He was admitted in boyhood as a chorister of that prince's chapel, and, having gained his notice by aptitude in learning, was sent by him to Paris in 1473, as companion to his son. At Paris, Reuchlin prosecuted his studies with advantage, especially in Greek; and not to follow minutely his wandering course, we find him successively at Basle, Orleans, Poitiers, and lastly, Tübingen, where, having previously taken his degree in law, he commenced practice as an advocate, about 1481. In 1482 he visited Rome, and other of the chief towns of Italy, as secretary to the count of Würtemberg, enjoyed and profited by the society of the most learned men of the age, and was received at the court of Lorenzo de' Medici with distinguished respect. On his return to Germany, he took up his abode at Stuttgard; and, from 1484 to 1509, filled a variety of high legal and diplomatic functions. In the latter year he became entangled in a long and harassing dispute, arising out of an edict obtained by Pfefferkorn, a converted Jew of Cologne, authorising him to examine and burn all Jewish books containing anything against the Christian religion. Reuchlin, on being referred to, gave his opinion decidedly against the justice of this measure; and in answer to a work of Pfefferkorn, entitled 'Speculum Manuale,' wrote the 'Speculum Oculare,' in 1511. This book was censured by the Cologne, Paris, Louvain, and other universities, and involved him with the Inquisition, before which, in 1513, he was summoned to appear at Mainz. Reuchlin appealed to the pope; and the pope referred the matter to the bishop of Spire, who pronounced the 'Speculum Oculare' to be neither dangerous to the church nor favourable to Judaism. Still the universities persisted in their condemnation, and even ordered the book to be publicly burnt; and in 1516 the cause was still in course of hearing at Rome, when it was stopped by the pope, and the disputes consequent on the rise of the Reformation prevented its being revived. In the troubled times which followed, Reuchlin had his share of distress and poverty. In 1518 he accepted, and held for a short time, the Greek and Hebrew professorships at Wittenberg; and he afterwards taught Greek and Hebrew at Ingolstadt for somewhat less than a year. In 1520 or 1521 he was appointed to the same chairs at Tübingen, a pleasant gleam over the close of his troubled life; for every comfort and facility were afforded to him, and crowds of students from all parts of Germany testified the respect in which his name and learning were held. Infirmity and sickness however soon compelled him to resign this employment, and he died at Stuttgard, June 30, 1522.

As a scholar, Reuchlin's name stands high among the men of his age. He was suspected of a leaning towards the Reformed doctrines, which the liberality of his views on the Jewish question no doubt tended to confirm. Be this as it may, he never separated himself from the Roman church. His numerous writings comprehend some elementary works on Hebrew, esteemed in their day, but of course long since obsolete; and some treatises on the cabalistic art. His fluency and purity in speaking both Greek and Latin were great, and highly admired.

REUSS is a principality in the interior of Germany, consisting of a part of the antient Voigtland, which was governed by the ancestors of the princes and counts of Reuss. It is situated between 50° 20′ and 51° N. lat., and between 11° 40′ and 12° 20′ E. long. It is divided by the circle of Neustadt, which belongs to Saxe-Weimar, into two portions, of which the southern is much the largest; the lordships of Greitz, Burg, Schleitz, and Lobenstein, with the bailiwick of Saalburg, form the southern portion, bounded on the north and east by Saxony and Saxe-Weimar, on the south by Bavaria, and on the west by Saxe-Coburg and Schwarzburg Rudolstadt. The principality of Gera, which is the northern part, is bounded on the north by Prussia, on the south by Saxony, and on the east and west by the different parts of Altenburg. The area of the whole is 580 square miles, and the population in 1838 was 101,[illegible]

The country, especially the southern part, is mountainous, being traversed by the Erzgebirge and the Thüringerwald, here called the Frankenwald, in which the Sieglitzberg is 2300 feet, and the Culm 2260 feet in height. There are many extensive well-cultivated valleys, of which the two great valleys watered by the Saale and the Elster are the most fruitful. There are also fine forests of pine and other timber, and rich pastures. The natural productions are corn (but not sufficient for home consumption), garden vegetables, fruit, hops, flax, and timber; horned cattle, sheep, game, and fish. The mineral kingdom yields iron, copper, lead, some silver, alum, gypsum, vitriol, and salt. The inhabitants are very industrious, and have manufactures of woollen, calico, stockings, hats, earthenware, china, tobacco, alum, vitriol, and have breweries and iron-works. [GERA.] They carry on a considerable trade with the adjacent countries; they export also cattle and timber. The public schools are on a good footing; there is a high school at Gera, a lyceum at Schleitz, and a Latin school, a seminary for the education of schoolmasters, and another for the clergy at Greitz.

The family of the princes and counts of Reuss is very antient, and may be traced back as sovereign princes to the eleventh century. This family has been repeatedly divided and subdivided into numerous branches; it now consists of two principal lines, the elder and the younger, and some collateral lines. The elder line, that of Reuss-Greitz, possesses the lordships of Greitz and Burg, and part of the district of Reichenfels. The prince resides at Greitz, a town containing 6200 inhabitants. The possessions of the younger line, that of Reuss-Schleitz, are considerably more extensive than those of the elder, but this line being subdivided, the revenue and territory are also divided, though only the prince of Reuss-Schleitz is considered as sovereign.

Branches.	Area of Territory in Sq. Miles.	Population.	Prince's Revenue. £
1. Reuss, elder line	143	32,000	14,000
2. Reuss, younger line, viz.:			
a. Reuss-Schleitz	128	20,500	20,000
b. Lobenstein Ebersdorf	163	28,500	18,000
c. Gera	151	30,800	20,000
	585	111,800	72,000

The branch of Gera having become extinct in 1802, the princes of Reuss-Schleitz and Lobenstein administer the affairs of the country in common, and divide the revenue equally between them. All the princes of Reuss have borne the name of Henry ever since the eleventh century. At first they were distinguished by some appellation, such as the elder, the younger, the rich, the fat; and in the sequel by the ordinal numbers. In 1668 it was agreed that the two lines should reckon separately. In 1701 both lines began with the new century with No. I.; but in 1801 the younger line began a new series with No. I., while the elder continue to count on. All the subjects of both lines are Lutherans, except about 500 Moravians and 370 Jews. The government is monarchical, with estates on the antient German model. In 1813 both lines joined the German Confederation; Reuss, together with Hohenzollern, Liechtenstein, Schaumburg-Lippe, Lippe-Detmold, and Waldeck, has one vote (the sixteenth) in the diet of the Confederation; in the full council each line has one vote. The elder furnishes a contingent of 223 men, the younger of 522 men, to the army of the Confederation. Each pays 250 florins annually to the federal treasury.

(Hassel; Cannabich; Stein; Hörschelmann; *Conversations Lexicon.*)

REUTLINGEN is the chief town of a bailliwick of the same name in the circle of the Schwarzwald, in the kingdom of Würtemberg. It is situated in 48° 29′ N. lat. and 9° 12′ E. long., at the foot of Mount Achalm, on the river Echatz, in a beautiful and fertile country. It is surrounded with moats, lofty walls, and towers, and has four principal gates, but within these few years the walls have been broken down in several places. Without the walls there are three small suburbs. The interior of the town is regularly laid out, but it is not a very pleasant-looking place, the houses being neither large nor handsome. Considerable improvements have however been made. The only remarkable building is St. Mary's church, built in the Gothic style entirely of freestone, which was founded in 1273, and finished in 1343. The steeple, which is very handsome, is said to be 325 feet high. Besides St. Mary's there are three other churches. The town-house is a considerable edifice, and the building called the Chancery, formerly a Franciscan convent, but now converted into government offices, is a very large structure.

Reutlingen is a thriving town. The inhabitants, now nearly 12,000, have considerable manufactures of woollen cloths, cotton, leather, hats, cutlery, &c. In the neighbouring country are raised some fruit and corn, in which, as well as in their own manufactures, the inhabitants carry on a considerable trade. Reutlingen was famous as the chief seat of literary piracy in Germany; but this scandalous species of pilfering is now prohibited by law in Würtemberg.

In 1240 Reutlingen, with a territory of fifteen square miles, became a free imperial city, and continuing faithful to the Swabian emperors, bravely defended itself against their adversaries. In 1305 it obtained the right of being a place of refuge for persons who had committed involuntary homicide. It afterwards joined the Swabian Union, and in 1505 placed itself under the protection of Würtemberg, on which it obtained, in 1506, the right of not admitting any Jews. In 1519 Duke Ulrich of Würtemberg besieged and took it, but was expelled by the Swabian Union. In 1530 it was one of the five free imperial cities that subscribed to the Confession of Augsburg. It lost its rights as a free imperial city by the treaty of Luneville, and by the recess of the empire of 1803 it was assigned to Würtemberg.

REVAL, or REVEL (in Russian, *Kolywan*, and in Esthonian, *Tallin*), the capital of the Russian government of Esthonia, is situated in 59° 26′ N. lat. and 24° 35′ E. long., on the Gulf of Finnland. It is very strongly fortified, and in 1824 the harbour was made capable of receiving the Russian Baltic fleet. It has much the appearance of many of the towns of Northern Germany, with narrow irregular streets and dark old-fashioned houses. The best part of the city is the part called the Dom, which is in fact a distinct portion, being surrounded with walls and towers in the old style. It is on an eminence called the Domberg, on the west side of the city, commanding an extensive view of the sea. Most of the houses of the nobility are in this part. There are likewise two extensive suburbs. In all there are 1900 houses, of which 1000 are in the suburbs; and 15,000 inhabitants, a large proportion of whom are Germans. The principal public buildings are the churches, of which there are six Russian, one Roman Catholic, and five Lutheran, including the cathedral, which has a very lofty and handsome steeple.*

There are numerous public and private schools, a gymnasium founded by Gustavus Adolphus in 1631, a theatre, a naval and military hospital, and a Bible society. The manufactures are cotton goods, hats, stockings, leather, powder, starch, needles, earthenware, looking-glasses, &c. There is also a cannon and bell foundry. Reval has a very considerable trade, which is chiefly in the hands of opulent German houses. Above one hundred merchantmen annually arrive in the course of the season, and leave before the winter sets in.

REVELATION (removal of a covering, or discovery) signifies, in theology, a preternatural or extraordinary communication made by the Deity to men. Every communication so made, without limitation as to the subject-matter of it, is of course a revelation; but we shall restrict the use of the term here to communication of knowledge pertaining to religion; that is, knowledge of the relation in which man stands to the Deity, and the will of the Deity respecting him. The fact of a revelation supposes a want, partial or entire, of religious knowledge on the part of man, which he is himself unable to supply. Whether the absence of such knowledge should be attributed to the absence of faculties requisite for attaining it, in the original constitution of man, or to the loss or depravation of those faculties, is a question with which the present subject is not necessarily concerned. It is assumed that he who believes a revelation to have been made, believes it to have been needed; and the admission or denial of this need will materially influence the inquirer as to the amount of other evidence which he may require in support of any particular revelation. A doubt respecting the need will make him cautious in accepting anything which professes to be a revelation. A full persuasion of it will oblige him to accept that which amongst others most recommends itself to his judgment. It is hardly necessary to observe that the fact of a revelation supposes also the being and providence of a God. There must have been an answer to the question whether there is a God, before the question whether he has made a revelation can arise.

The evidence of a revelation may be considered with reference to the party to whom it is first and immediately made; to those who have their knowledge of it immediately

* Stein's 'Lexicon,' published 1820, says the cathedral was destroyed by lightning on the 28th of June, 1820, but Hörschelmann and Cannabich, in 1833 and 1835, describe it as still existing.

from him; and to those who possess only a recorded account of it. It should seem that in the case of the first recipient, the only evidence fully satisfactory must be something external to himself, or unequivocally presenting itself to the judgment of his senses. For so far as we know, or have reason to believe, there is no kind of internal consciousness which alone affords a test by which a preternatural communication may be detected in the mind. It is not meant, nor is it necessary to suppose, that in the case of repeated communications to the same individual there must be a repetition of the external proof. For in the first communication, so ascertained, the means might be given of ascertaining the character of all future communications. When the first recipient communicates what he has received to others, he must produce evidence similar in kind to that which establishes the reality of it to his own conviction; in other words, the miraculous sign must here also accompany the communication, or have previously stamped credibility on the party commissioned to make it. To him this kind of evidence is a security that he is not deceived; to others, that he is neither deceived nor a deceiver. We are supposing a general publication and permanent knowledge of the revelation in the world; for it is conceivable that a few persons to whom the character of the publisher, moral and intellectual, was well known, might not unreasonably be satisfied with his bare assertion of the revelation and the circumstances attending it: but this would obviously be insufficient where the revelation claimed to be received by whole communities and future generations.

Those who live at a time remote from that in which the revelation was given, must rely, as to the evidence which first established its origin, on historical testimony; which must be tried by the common rules belonging to that subject. If it is asked why preternatural intervention is claimed in behalf of those to whom the revelation is delivered by the first receiver of it, and dispensed with in the case of those to whom only the record of it has descended, the answer is, that a miraculous fact is a subject for historical testimony; and if confirmed by that, conveys to future generations the same kind of security which it was intended to afford to those who witnessed it. It should be observed that in some cases the miraculous character of a revelation may be established subsequently to, and at any distance of time from, its first publication, as in the case of the fulfilment of a prediction; and by any preternatural fact which, however separated in time, is connected necessarily with the revelation.

In saying that a miracle is the proper test of a revelation, we do not mean to exclude every other kind of proof. We mean only that a miracle is that one species of proof which cannot be spared. Many circumstances may be supposed to have place in a revelation, which would contribute greatly to confirm its reality, and which might with some minds have more influence in inducing acceptance than even the proof of miraculous agency.

The matter of a revelation especially is an important element in the general mass of proof on which it should rest; and this perhaps deserves a little further consideration. It may at once be admitted that men, being in the position in which they must be supposed as needing a revelation, cannot know beforehand what this revelation should be. Indeed the very necessity we have supposed for miraculous intervention supposes an inability in the first instance to distinguish, by the mere matter of a revelation, whether it be or be not of divine origin. Neither can it be fairly assumed that men, enlightened by the discoveries of a real revelation, must be competent judges of the internal marks which distinguish it as such, so as to be able to say universally what God would or would not have revealed, and what could have been discovered only by him. For this would require men to be placed in a position which, as objects of a divine revelation, they cannot fairly be supposed ever to occupy. In order to appreciate fully the merits of any system of instruction or moral government, it is obviously necessary that all its ends should also be fully comprehended and appreciated; as in the case of a complicated machine, all the purposes which it is intended to answer must be known, if we would comprehend the use of all the contrivances employed in it. The moral machine which we are considering must be examined from the same elevated point of view from which it is contemplated by its author, before we can assure ourselves that we are competent to sit in judgment on all its provisions. And the case here is not as the case of human instruction, where the learner may become as wise as the teacher. When men have been enlightened up to the highest point of knowledge to which we can suppose them capable of attaining, there must still be an interval between the human subjects of the divine government and the supreme governor not only of the world which they inhabit, but of the universe, of all that is and all that shall be; an interval such that the system of his government can be brought only partially, and to a very limited extent, within the field of human vision. And the connection of that part of his government in which we are placed, with others, cannot be known at all, though the fact of the connection can hardly be doubted. But when all this has been granted, there still remains to the matter of a revelation an important place among the circumstances which may contribute to confirm or disprove its pretensions to a divine origin.

It is not, we believe, disputed that the actual position and prospects of men among existing things, the fact and conditions of their existence, present difficulties which, when considered with reference only to what is, has been, and from experience of the past may be expected to be in the world, admit no solution which will perfectly satisfy inquirers. There are anomalies which perplex and baffle our reason, and there is a want of something to explain or remedy or encourage, which men have not been able to supply; and the supposition of a presiding Providence is of itself so far from removing these difficulties, that it discovers some and aggravates others. Now, whatever coming in the shape of a communication from God should appear to throw light on this darkness, to afford a clew out of the labyrinth, would bring with it a reasonable prejudice in favour of its pretensions; and if, further, from what we know of the history of man, the progress of human knowledge, and the achievements of human intelligence, we might fairly infer that its discoveries were beyond the reach of man's natural powers, then this internal mark would amount to a proof of a very cogent kind. On the other hand, an entire absence of this mark, an entire failure to satisfy our demands on this head, would at least be a discouragement to belief, which it would require the strongest evidence on the other side to overcome.

Again, there may be positive disproof of the pretensions of a revelation from the matter of it. There are notions respecting the deity and moral obligation, the violation of which in a professed communication from God would produce at once a persuasion of imposture which no kind or degree of evidence on the other side could remove. This part of the subject it is not easy to handle satisfactorily, being encumbered with metaphysical as well as moral and theological difficulties. Whether there is in man an innate notion of a deity, and a conscience or moral sense, are questions with which we shall not meddle. It is assumed that men have in fact a notion, however planted or learnt, of a distinction between right and wrong, as something eternal and immutable, and certain persuasions respecting the nature and attributes of the deity, so as to be able to say with confidence that certain things cannot be attributed to God, certain things could not have been taught or commanded by him. This measure of religious knowledge, which we suppose men naturally to possess, or by the use of their natural reason to be capable of attaining, constitutes what is commonly called natural religion, in contradistinction to revealed: and we mean to say that a real revelation cannot be at variance with enlightened views of this natural religion, and must in a certain sense be founded upon it. Men will and should compare the subsequent revelation with the original gift. The comparison indeed will not always issue in the same result. There have ever been among men notions of a deity and moral obligation so discordant and contradictory, that an assigned attribute or command which would recommend an offered revelation to some, would be a disproof to others; and it may be said that when we speak of enlightened views of religion we mean in fact the views which we happen to entertain. Neither can we completely separate by a broad and distinct line genuine moral instincts, or discoveries made by the legitimate use of faculties given to us for the purpose of making them, from prejudices dependent on varying circumstances, and depraved or artificial habits of thought; and it must be acknowledged that whilst none, as we have already observed, can judge universally what is and what is not inconsistent with the notion of a communication from God, there are some who are incapable of judging at all in this matter. Yet

It cannot be said that the test we have proposed, so far as we have admitted its application, is therefore useless and practically unsatisfactory, without disallowing on the same grounds appeals necessarily made and universally accepted in analogous cases which will readily suggest themselves, in natural laws, to the actions, feelings, and opinions of men. Neither is there any real difficulty from the supposed vagueness of the expression when we speak of enlightened views of natural religion. It is probable that the greater number of men now existing believe that the sun and moon are equally distant from the earth. To them a *physical* revelation which confirmed this supposition would not be objectionable, whilst it would be rejected on that ground alone by those who had what we may venture to call more enlightened views of the subject. It would have been tried by them and condemned on the legitimate application of a sufficient test: nor on the trial of a revelation of religious truths ought a test founded on worthy notions of the deity gained from natural religion to be considered less valid because there may have been and still may be whole communities of men capable of accepting a revelation which proposed to them deities in human form, possessing all the human passions, and freely indulging them all. It can hardly be said that we appeal more truly to nature when we appeal to her in a debased rather than in an improved condition; and it may be that those notions to which in a certain state of society we give the preference, ought not to be considered so much in the light of acquisitions made by refinement, as of natural instincts extricated and set at liberty from a state of insertion to which perverted habits had confined them. That in allowing the use of the test in question it is impossible absolutely to fix the limits of a safe and legitimate application, is a disadvantage necessarily belonging to such a subject, from which a process of rigid demonstration is excluded.

We have spoken of a miracle as the test of a revelation, without attempting a definition, believing the common notion of it to be sufficiently accurate for our purpose. For the distinctive character of a miracle, and the possibility of proving it by evidence, the reader may consult the article MIRACLE in this work, and the authors referred to at the end of it. It is presumed that the purpose of the miraculous test is evident. A certain person is converted to the belief of certain truths by an appearance, undoubtedly miraculous, in the sky. The miracle is to him a proof that his conversion is from God. He teaches to others the truths which he has been made to believe; and in doing this performs miracles. These are a proof to them that he is commissioned by God to teach what he delivers; recorded and duly attested, they prove the same to those who have not witnessed them. All the parties, in accepting the test, would reason in the same manner, namely, that the laws of nature could be changed only by God, the author of them, or by his permission; and that he would not change them or permit them to be changed for the purpose of establishing a falsehood.

The question may perhaps be raised, whether, the necessity of a revelation being admitted (and with the proofs of this we have no concern in this article), we must also admit the necessity of its being known to be such by those to whom its contents are proposed. We have shown that the matter of a divine revelation cannot be expected to be fully and altogether subjected to the judgment and expectations of men; and we shall only observe further, that a religion for men who need the interposition of a revelation, must contain not merely abstract truths ending in themselves, but such as convey motives and rules of conduct; which, in order to their practical effect, must be held with the constraining force of a belief that they have been authoritatively proposed by one who has the power to enforce their acceptance.

To the question, 'has a revelation been actually made?' the Christian believes that he has an answer in the possession of the Holy Scriptures, or the books of the Old and New Testament. An account of the contents of these books and an examination of the evidences of the Christian revelation form, of course, no part of the subject of this article. The proofs which we have insisted on as requisite to establish the reality of a revelation generally must, if rightly assigned, be applicable to this particular one.

We insisted on the primary evidence of miraculous agency in the communication, with corroboration from the matter communicated, the miraculous agency to be so exhibited to the witnesses as to be capable of proof from testimony to others. Particular revelations may be supposed, according to the circumstances under which they were given, and the nature of their contents, to admit various sorts of evidence; almost all of which however will probably be found to resolve themselves into one or other of these two, though all inquirers may not agree in the classification. We should place for instance under the head of proof from preternatural manifestations, the fulfilment of prophecy in cases supposed to be beyond the reach of human foreknowledge or conjecture; the alleged existence of persons exhibiting qualities, moral or intellectual, in kind or degree, not exemplified or to be expected in others of the human race; conduct of men, natural under the supposition that they were conscious and had proof of a divine commission, but otherwise unaccountable according to any known motives of human action.

The purpose and value of what may be called the corroborative evidence as distinguished from that founded on miraculous agency can hardly be overrated. Between the highest degree of certainty with which a fact can be invested by evidence, and the faintest probability, there is room for every shade of assurance.

Now it is notorious both that different minds are differently affected by the same evidence, and that some minds seem peculiarly constituted by nature to admit the full force of one mode of proof, whilst they are comparatively insensible to another; so that it might happen that whilst to one inquirer the testimony which supported the story of the miraculous facts seemed so strong as to supersede the necessity of confirming his belief in the revelation by the evidence which the matter of it might supply, and which perhaps he might be little able to appreciate, another might rather find that the miracles were so far proved as to complete the satisfaction which he had already derived from the other source.

The Christian revelation, which may be considered as forming one subject with the Jewish, from the wide field over which it is spread and the miscellaneous character of its contents, must necessarily supply, in large abundance, matter for examination in the way of evidence. An enumeration, which however does not pretend even to approach completeness, of the constituent parts of the body of evidence belonging to it, together with the proper mode of using them and estimating their joint force, may be found shortly but very clearly proposed in the first of Mr. Davison's 'Discourses on Prophecy.' Before we leave this part of the subject, we would observe, what seems sometimes to be overlooked, that an action may itself be a revelation. It would not be improper to say that the birth, death, and actions, even more than the discourses of Jesus Christ, were a revelation, of which the Apostles, who taught what are called the doctrines of Christianity, were only the interpreters. Of these doctrines it is not our business to treat, but we will select one as the subject of a few observations, merely with a view to illustrate what was said in a former part of this article, on the disposition of mind with which we must necessarily regard the pretensions and evidences of a professed revelation, according as we recognise, or not, a need which men have of extraordinary information on the subject of religion. The doctrine we select is that of the immortality of the soul and a future state of rewards and punishments. Without assuming the probability or improbability of this doctrine, we suppose it to be notorious that the immortality of the soul, or some kind of continued existence after bodily death, with liability to a state of happiness or suffering, has been very generally believed, in one shape or other, in all parts and at all periods of the world; and that this doctrine is distinctly delivered and prominently set forth in the New Testament. There is as little doubt that before the time of Christianity, either the notions commonly received of a future state were so irrational, or the belief of it so faint and unassured, that for the most part it had comparatively little effect on the moral feelings and conduct of men; and that on the other hand, wherever the Christian revelation has been published, this doctrine, whether true or false, has not only been firmly received with little variation in the manner of understanding it, but has influenced the conduct of many, happily or not, in the most important respects, and regulated the whole course of their lives. It is plain that those who regarded the distinct and authoritative announcement of this doctrine to be among the things especially needed by mankind, and those who considered it to be either useless or mischievous, would be very differently impressed by the general body of evidence in favour of the revelation.

Among professed revelations which have been the ground of a national religion, it may be doubtful whether we should place the mythological systems of antient Greece and Rome. They are indeed avowedly founded on traditional accounts of certain transactions between gods and men; but from the nature of the transactions, of the supernatural beings concerned in them, and the purposes of the interference, we may doubt whether the discoveries supposed to be made belong to the notion of a revelation according to our definition of the word, or the usual acceptation of it. The same for the most part may be said of the mythology of the Hindus and of the northern nations of Europe. But there can be no doubt that the religion of Mohammed, as taught in the Korán, professes to be founded on a revelation in the strict sense of the word, such as may be subjected to the same tests which we have supposed to be applicable to all revelations.

In passing from the Christian revelation itself to the written record of it, a new and important question is opened to us. The revelation may have been made to the persons who profess to have received it; but in recording it also, were they preternaturally assisted, or were they left to the use of their natural memories, and the guidance of their unassisted judgment? In other words, we are met by a question respecting what is called the inspiration of the books of Scripture, or, more properly, of the persons who wrote them. By this word we are to understand, not the preternatural infusion of revealed truths into the minds of the writers (which however would not be inconsistent with the original meaning of the word), but preternatural assistance in recording what had been so infused. This distinction should be observed. St. Paul, if we believe his own declaration, received immediately from God a message to men. He may be supposed to have delivered this message orally or in writing to others from memory; and in that case he would have been a deliverer and they receivers, in the strictest sense of the words, of a divine revelation; but the message, so delivered would not in theological language have been an inspired message, that is, spoken or written under inspiration. It is beside our purpose to defend or impugn the doctrine of the inspiration of Scripture generally, or, out of the various theories which have been put forth, to advocate one in preference to the others. We only wish to do something towards clearing away certain fears and difficulties, which seem to beset and mislead many in the very outset of the inquiry, and to offer a few suggestions as to the principle on which the inquiry should be conducted, to those who are not very conversant with the subject.

In the case of most persons educated in the Christian faith, their first introduction to the Bible is accompanied by an assurance that it was dictated by God, and is *therefore* true; and this is told them at a time when its claims, as an authentic history, independently of its inspiration, neither are nor can be explained to them. This early impression, perhaps unavoidable, that the Scriptures are to be received as true, *only* because they are the Word of God, is probably retained for the most part without question, in spite of its inconsistency with the method and object of books which are given, almost as universally as the Bible, to all educated persons for the purpose of establishing their faith on rational grounds. Hence they are habituated from the very nursery to confound in their minds two questions essentially distinct, the divine origin of the Christian religion, and the divine origin of the scriptural records of it. All might easily remove this confusion by simply answering the question, what would be the natural course of our inquiries, and by what steps should we arrive at conviction of the divine origin of the Christian religion, if the volume of the New Testament were for the first time put into our hands for examination, at an age when we were capable of making it? It is obvious that we should not begin with assuming the inspiration of the writers; for that would be assuming the very point in debate, assuming that for which we had not as yet a shadow of evidence. But neither is it of their inspiration that it would be our first object to find evidence; for such evidence could not at first be obtained. If we ever came to the conclusion that they were inspired, it must be because either the very supposition of a revelation from God included in it the supposition of a revelation on the part of those who communicated it, or because all the writers themselves claimed inspiration, or some, whose claims we had already allowed, attributed it to the rest. In the former case we must *first* have believed that a revelation was made; in other words, that the origin of the religion was divine: in the other, if we assent to the claim of inspiration, we must *first* have admitted the credibility, the veracity of those who make it; that is, if we believe them to be inspired because they say so, we must have had reason for believing what they say, on other ground than that of their inspiration. It seems then that it would be our first object to establish not the inspiration, but the credibility of the sacred writers apart from their inspiration. We should proceed from the establishment of their credibility, to inquire, in the second place, if they were inspired. The result, in short, to which we have actually come is this: the New Testament is put into our hands for examination, and we find that the claims of Jesus and his followers to a divine commission rest on the miracles which they are said to have performed. Our belief of the fact of the miracles depends on the credit we attach to the story of the witnesses. If that is substantially true, Jesus came from God. With the arguments by which the credibility of the gospel history is proved we have here no concern. It is plain that it is not proved by the inspiration of the authors. Some confusion seems to have arisen from a strange mistake respecting the kind of satisfaction which the inspiration of the sacred writers, when established, is capable of supplying. It does not confirm their veracity, it only implies their accuracy. It secures us from their mistakes, not from their falsehood. Now if it should be argued that without inspiration we can have no assurance that they were not mistaken, when they tell us that they saw a man dead on the cross, laid in his grave, and afterwards alive, it may be asked, how can they be secured from their liability to mistake, when they tell us that they are inspired? It is at least as likely that they should be mistaken in the one case as in the other. The obvious truth is, that if we cannot rely on their veracity when they vouch for miracles, we can trust none of their assertions, and admit none of their claims; and if they might be mistaken as to the fact of a miracle, they might be equally mistaken in their claim of inspiration for themselves or for others.

It is hardly necessary to observe that the various methods followed by writers on the evidences of the Christian religion are all in conformity with the view that has been taken of this subject. They endeavour to show the genuineness and authenticity of the books of the New Testament, the fidelity, disinterestedness, and integrity of the writers; to point out their means of information as human historians, and to confirm the accuracy of their accounts by comparison with other records. The question of inspiration forms no part of their inquiry. It is beside their object, which is to prove the divine origin of Christianity; and this is fully proved if their arguments are satisfactory.

It is not meant, of course, that all who are brought to a conviction of the truth of Christianity, arrive at it in the same manner. It is sufficient for our argument that it may be reached in the manner we have supposed. In short, on whatever support the believer himself may eventually feel that his faith habitually reposes, if he should ever be impelled by any motive to trace his conviction to a source from which it can be shown to others by reasoning that it may legitimately flow, he will find that he must rely, in the first instance, on the credibility of the sacred writers, however established, considered as uninspired historians. With this foundation laid he may commence an inquiry into the proofs of their inspiration; and he may pursue it with a full assurance that to whatever result it may lead, the divine origin of his religion is already secured; that he has in possession a revelation from God, truths divinely communicated to men. We may seem to have taken unnecessary pains to establish a point too plain to be disputed. Our justification must be, that it does not seem to have been so plain to some even of those who have written on the subject, and are occasionally quoted as authorities, and who have been led, apparently by the confusion which we deprecate, into unwarrantable insinuations of infidelity against those who differ from them in opinion.

If the question should be asked, where, when the divine origin of the religion is supposed to be established on the credibility of the sacred writers, we should look for proof that the books which are the records of it were written under the security of inspiration? the natural answer would be that it must be looked for in the books themselves, from the claims, declarations, and intimations of the writers. When, for example, one of the evangelists has recorded a distinct promise made by their master to his Apostles, of a divine gift for the declared purpose of assisting the memory and enlightening the understanding, the inference seems to be unavoidable that those to whom the promise was given must have written with more than natural advantages. The argument founded on the necessity of inspiration to render the sacred books effectual for the purpose for which they were intended, ought not perhaps to be slighted. We have seen indeed that the supposition of the divine origin of the religion does not necessarily require the admission of inspiration; yet the peculiar character of the contents of the books, together with the service they were destined to perform, may raise a presumption in its favour. The direct testimony however from the writers themselves must be principally regarded. But when commencing the examination, whilst the evidence is yet to be found, we must be careful to estimate correctly the degree of authority which ought in this stage of the inquiry to be attributed to the words of Scripture. They are not yet proved to be the words of God. The declarations of the writers must be received and interpreted fairly and liberally, as the solemn declarations on a solemn subject, of honest and credible writers, ought to be received and interpreted. If the evidence which we seek to obtain from them cannot be obtained in this manner, it cannot be obtained at all. To search Scripture for proofs of its inspiration whilst at the same time we assume it to be inspired, is a proceeding so obviously absurd, that if experience did not teach us otherwise, any caution against it would seem to be unnecessary. But even when this strange error is not committed, declarations of the sacred writers, apparently bearing on this subject, may be and often are improperly summoned to the cause. When a writer professes to have received secret suggestions from the deity, that is, to be the subject of inspiration in one sense of the word, he is represented as claiming it in the other, as though the privilege of receiving communications necessarily implied the privilege of infallibility in recording them. This confusion has been noticed on another occasion.

That most popular argument for the inspiration of a particular book, founded on testimony borne to the purity and integrity of the canon of Scripture, may be soon disposed of. When it has been proved that a book forms part of what is called the canon, it may follow that it forms part of Scripture. This will not carry us far when the question to be decided is, what are the claims of Scripture to inspiration?

There is one mode of proof, besides those already mentioned, which ought perhaps to be noticed, as being much in favour with some theologians, namely, an appeal to what is called the tradition of the church. There are some advocates of inspiration, in the strictest sense and most unlimited application of the term, who allow, or rather contend, that the proof of it rests mainly, if not entirely, on the testimony of tradition. An examination of the value of this testimony would oblige us to enter more largely, than would here be expedient, on the important question of ecclesiastical tradition generally. We shall content ourselves with saying that, in this case at least, we greatly doubt, for many reasons, the sufficiency of the witness, and are not satisfied, even where it speaks to the purpose, that its words have always been rightly understood. However this may be, it is plain that this mode of proof also supposes the question of the divine origin of the Christian religion to be independent and to have precedence of the question of inspiration.

We shall close this article with a brief notice of the three most popular theories of inspiration, which are distinguished from each other more in respect of the extent to which they attribute inspiration, than in respect of any difference in the meaning assigned to the word.

That which is called verbal inspiration supposes each word in the Bible, as we now have it, with due allowance made for mistakes of transcribers, to have been irresistibly dictated by the Spirit of God, the writers being only vehicles of words and thoughts not their own. This notion of inspiration has undoubtedly still its advocates; but we are not aware that it is at present maintained by any divine of repute. According to another theory, somewhat modifying the former, the writers were allowed to exercise their own judgment in the choice of their words; but in the meaning of each sentence, from the first verse of Genesis down to the last of the Revelations, they have been secured by supernatural interference from the least particle of error. This theory, which is not without support from well-known theologians, represents perhaps more nearly than any other the popular creed. Lastly, there are many, and amongst them divines of great eminence and reputed orthodoxy, and not a few distinguished prelates of the English church, who limit the extent of inspiration as commonly received, and suppose that parts of Scripture may have been written with the liability to error incident to ordinary histories; those for instance which are purely historical, and contain no religious truth. As to the degree in which this limitation is to be admitted, and the number and length of passages to be excepted from the sanction of inspiration, there is of course room for diversity of opinions, which affords apparent ground for objection to the theory itself. The advocates of the two former theories contend that a latitude for choice is allowed which is capable of a dangerous abuse. The truth of the allegation cannot be disputed; but perhaps it is not possible by any device to exclude the danger which alarms them. The canon of Scripture has not been ascertained to us by an authoritative revelation, nor has the purity of the text been absolutely secured by providential interference. A liberty is thus left, which in these cases also may become dangerous to those who are willing to abuse it. Some however may think that the test of sincerity and right intention, and the means of probationary discipline which the allowance of such a measure of discretion affords, is apparently in harmony with what we have been taught of God's moral government of the world. On the other hand it is objected to the advocates of the more rigid theories, that the faith of the believer is exposed to still greater danger by the forced constructions and violent treatment of the text which their systems have often induced them to employ.

It is plain that reliance on the truth of the Scriptures generally, as containing a divine revelation, can in no respect be strengthened by the belief in plenary inspiration. On the other hand, since those who have identified in their minds the plenary inspiration with the truth of the Bible, must with the one abandon the other, the indisputable detection of even a geographical or chronological error, however unimportant in itself, of a discrepancy between the sacred writers, irreconcileable by any legitimate process, as to a single circumstance, however minute and trivial, in recording the same fact, must destroy their faith; and hesitation as to the possible removal of such difficulties must impair or disturb it. It is absurd to suppose that any theory of inspiration can reconcile us to such a quantity of error as would overthrow the credibility of ordinary historians; for the presence of it in the Scriptures would be fatal to the only evidence on which their inspiration in any sense can be reasonably maintained.

It might perhaps have been expected that we should notice a certain classification of the phenomena of inspiration of which many theologians are fond, certain distinctions in kind, under the titles of impulsive, suggestive, superintending, and many others. The truth is, we think them to be of very little value on any view of the subject. They seem to have been adopted by theologians who hold the theory of plenary but not verbal inspiration, from a wish to remove the necessity of supposing a greater quantity or degree of miraculous agency than the occasion required.

We have drawn none of our materials from the writings of a class of theologians who, regarding the Scriptures as in some sense, not very clearly defined, vehicles of religious truth, exclude all notion of revelation which is not equally applicable to discoveries made by human intelligence, and who give no credit to assertions of miraculous interposition, whether in conveying knowledge or attesting facts. Whatever consideration may be due to the writers, some of whom are men of ingenuity and research, their speculations could hardly have an appropriate place in the subjects to which this article is confined. [RATIONALISM.]

REVELATIONS, BOOK OF. [APOCALYPSE.]

REVELS, MASTER OF THE, an officer in noblemen's and other great houses, appointed *pro tempore* to manage the Christmas diversions from All-hallow-eve to Candlemas-day; more ordinarily called the *Lord of Misrule*. In the royal household however the master of the revels was a permanent officer, and was called Master of the Tents and Revels or Masks and Revels, whose business it was to keep the tents and pavilions belonging to the king, which were often, if not always, carried with the king upon removes and progresses. This officer had also the keeping of the dresses and masks which were used in entertainments given at court, and he was to provide such new ones as were wanted.

The permanent office of master of the revels was first instituted in the reign of Henry VIII. Queen Elizabeth divided the mastership of the revels into several offices, which, as vacated by death, were to be re-united. In 1663 we find two masters of the toils, tents, hayles (*i.e.* halls or temporary buildings), and pavilions, who again occur in 1674.

See the 'Archæologia,' vol. xviii., p. 318, &c., and 'The Loseley Manuscripts,' edited by A. J. Kempe, Esq., 8vo., Lond., 1836. Various papers in illustration of the office in Queen Elizabeth's time are contained among the Lansdowne MSS. in the British Museum. See also MS. Addit., Brit. Mus., 5750. No mention of this office has been found subsequently to the reign of King Charles II.

REVERSION. By a reversion, in the widest sense, is meant a right of property the enjoyment of which is to commence at some future period, fixed or depending on contingencies, and is to continue either for ever or during a term either fixed or depending on a contingency: anything in fact which is to be entered on, or which may be entered on, at a future time, is a reversion in books which treat on the value of property. The legal sense of the word is more restricted.

Thus an assurance of 100*l.*, or a contract to pay 100*l.* at the death of a given individual, is 100*l.* in reversion to the executors of that individual. Our object in this article is to treat of this most common species of reversionary contract, life insurance or assurance. At the time when the article INSURANCE should have appeared, the mania for forming new companies was at its height, which made us judge it advisable to defer the consideration of the subject, that the list which we proposed to give of such companies might be more complete.

The value of a reversion depends in a very easy manner upon the value of the corresponding annuity; that is, any given sum, say 100*l.*, to be received *when* a given event arrives, depends for its value upon that of 100*l.* a year to be received *till* the event arrives. Suppose, for example, that money makes five per cent., and that an annuity, say upon a life, is worth 14 years' purchase, upon the method of calculation explained in ANNUITY, p. 49. That is, 100*l.* paid a year hence, and again two years hence, and so on as long as the life lasts, is now worth 1400*l.* Required the value of 100*l.* to be paid at the end of the year* in which the life drops. We must now reason as follows:—Suppose a perpetual annuity of 100*l.* a year is to be enjoyed by A during his life, and by his legatees after him. By hypothesis A's portion is now worth 1400*l.*, and (money making five per cent.) the annuity for ever (INTEREST) is worth 20 years' purchase, or 2000*l.*; consequently the legatees' interest is *now* worth 2000 − 1400, or 600*l.* But at the end of the year of death the legatee will come into 100*l.* current payment, and a perpetual annuity worth 2000*l.*; for the remainder of a perpetual annuity is also a perpetual annuity: his interest will *then* be worth 2100*l.* Hence we have ascertained that 2100*l.* at the end of the year of death is now worth 600*l.*; and the rule of three then gives the value of any other sum: thus 100*l.* at the end of the year of death is now worth $\frac{600}{21}$*l.*, or 28*l.* 11*s.* $5\frac{1}{7}$*d.* Hence the following easy

RULE.—To find the value of a given reversion, subtract the value of the same annuity from that of a perpetual annuity, and divide the difference by one more than the number of years' purchase in a perpetual annuity: or multiply the excess of the number of years' purchase in a perpetual annuity over that in the life annuity by the reversionary sum, and divide as before.

Next, to find what premium should be paid for the reversion. A premium differs from an annuity in that a sum is paid down, and also at the end of every year: consequently it is worth one year's purchase more than an annuity. In the preceding question, the annuity was worth 14 years' purchase; consequently the premium now is worth 15 years' purchase. But the present value of all the premiums is to be also the present value of the reversion, or 28*l.* 11*s.* $5\frac{1}{7}$*d.*, whence the premium should be the 15th part of this, or 1*l.* 18*s.* 1*d.* Hence to find the premium, divide the present value of the reversion by one more than the number of years' purchase in the life annuity. But when, as most commonly happens, the premium is wanted without the present value, the following is an easier

RULE.—Divide the reversionary sum separately by one more than the number of years' purchase in the perpetual annuity, and one more than the number of years' purchase in the life annuity: the difference of the quotients is the premium required. Thus if in the preceding example we divide 100*l.* by 20+1 and by 14+1, or by 21 and 15, we find 4*l.* 15*s.* 3*d.* and 6*l.* 13*s.* 4*d.*, which differ by 1*l.* 18*s.* 1*d.*, the same as before.

The life we have been tacitly considering, when we talked of an annuity being worth 14 years' purchase, at five per cent., is one of about 36 years of age. The first impression must be, that the proposed premium is ridiculously small! Make it up to 2*l.*, and it will be 50 years before the premiums reach 100*l.* Some such consideration must have moved the law officers of the crown, in 1760, when they refused a charter to the Equitable Society, then charging a premium of about 4*l.* at the age of 36, on account of the lowness of their terms. But it is to be remembered that those who receive the premiums are to invest them immediately at five per cent., and are to invest the interest, thus making compound interest; persons aged 36 live, one with another, about 30 years, which is sufficient time for the premiums, with their interest, to realize 100*l.* for each person, one with another.

We now show the manner in which a simple result of calculation answers its end. To simplify the case, suppose an office starts with 5642 individual subscribers, each aged 30 years, the mortality among them being that of the Carlisle Table. [MORTALITY, p. 416.] The bargain is for a short assurance, as it is called, of 20 years, and of 1000*l.*; that is to say, the executors of each one who dies within 20 years are to receive 1000*l.* at the end of the year of death. Money makes three per cent. once a year. According to the table then, there are 57, 57, 56, &c. deaths in the successive years, and the following is the result, the proper premium being calculated at 11*l.* 12*s.* $3\frac{1}{3}$*d.* each person, or more exactly 11,614*l.* 16*s.* for 1000 persons. It is supposed that there are no expenses of management. By P is meant that premiums are paid, and the number paid precedes the letter: by *y*, that a year's interest is received, and by *c*, that claims, in number as stated, are paid; small letters denote a transaction at the end of a year, and the large letter one at the beginning; the age of the parties paying premiums is in parentheses at the beginning. Fractions of pounds are neglected, one pound being written for everything above ten shillings.

At the outset the office receives 65,530*l.* from the 5642 persons assured; this is immediately invested at 3 per cent., and yields 1966*l.* by the end of the year, making 67,496*l.* But at the end of the year the claims of the executors of 57 persons who have died during the year are to be satisfied, which requires a disbursement of 57,000*l.*, reducing the society's accumulation to 10,496*l.* The contributors who are left, 5585 in number, now pay their second premiums, 64,869*l.*, so that, these being immediately invested, the company has 75,365*l.* at interest during the second year. This yields 2261*l.*, so that by the end of the year 77,626*l.* is accumulated. Then comes the demand of 57,000*l.* on behalf of 57 contributors deceased during the year, which reduces the accumulation to 20,626*l.* This is more than it was at the same time last year, which is denoted by +. In this way the company goes on, accumulating to an amount which would lead a person unacquainted with the subject to conclude that the premium must be too large: in fact ten years give an accumulation of 91,809*l.* But now the state of affairs begins to change; the contributors have been diminishing, while the claims have been increasing, until the yearly incomings no longer equal the outgoings. The accumulations then come in to make good the difference in such manner that by the time the remaining contributors come to be 50 years of age, and the claims of 61 who died in their fiftieth year have been satisfied, there only remains 8*l.* of the 91,809*l.*; and this 8*l.* is merely the error arising from omitting shillings, &c. in the calculation. Something of the same kind must take place in every office which dies a natural and a solvent death; the only difference being that, when new business ceases, instead of a number of contributors all of the same age, and under similar contracts, both ages and contracts vary considerably.

There are certain tables which are variously named (sometimes after Mr. Barrett, the inventor, sometimes after Mr. Griffith Davies, the improver; sometimes after D and N, letters of reference used in them), but which we call commutation tables. They are described in the 'Treatise on Annuities,' in the *Library of Useful Knowledge*, and a copious collection is given: also in an article in the 'Companion to the Almanac' for 1840. They very much exceed in utility those which preceded them; and we shall here give part of one of them, namely, that for the Carlisle Table, at 3 per cent., which contains the materials for judging of the demands made by an insurance company in cases involving one life only. Opposite to each age of life are three rows of figures in columns marked D, N, and M: and by $M(x)$ we mean the number in column M opposite to the age x.

To find the value of an annuity of 1*l.* on a life of any age, divide the N of that age by its D. Thus, at the age of 35 the value of an annuity of 1*l.* is N(35)÷D(35), or 35126·57 ÷1905·57, or 18·433*l.*, or 18*l.* 8*s.* 8*d.* Thus, the following formulæ will be readily understood:—

Value of an annuity which is to commence immediately: that is, which is to make the first payment in a year (age x) .	$\dfrac{N(x)}{D(x)}$
Value of an annuity which is to commence in n years; that is, to make the first payment in $n+1$ years, if the party be then alive (present age x) . .	$\dfrac{N(x+n)}{D(x)}$
Premium for such an annuity, payable now and n times in all	$\dfrac{N(x+n)}{N(x-1)-N(x+n-1)}$
The same premium, payable $n+1$ times	$\dfrac{N(x+n)}{N(x-1)-N(x+n)}$
Value of a life annuity for n years; or payable n times at most .	$\dfrac{N(x)-N(x+n)}{D(x)}$
Present value of an assurance of 1*l.* at death . . .	$\dfrac{M(x)}{D(x)}$
Premium for the same . .	$\dfrac{M(x)}{N(x-1)}$
Present value of an assurance of 1*l.* at death if after n years .	$\dfrac{M(x+n)}{D(x)}$
Premium for the same, payable $(n+1)$ times . . .	$\dfrac{M(x+n)}{N(x-1)-N(x+n)}$
Present value of an assurance of 1*l.* at death if within n years	$\dfrac{M(x)-M(x+n)}{D(x)}$
Premium for the same, payable n times	$\dfrac{M(x)-M(x+n)}{N(x-1)-N(x+n-1)}$

As an instance, let us take the case of the last formula, which was proposed at the beginning of this article: the age is 30, and the term of insurance 20 years; we have then to divide the excess of M(30) over M(50) by the excess of N(29) over N(49):—

M(30)	932·6867	N(29)	47783·19
M(50)	555·9583	N(49)	15347·98
	376·7284	div. by	32435·21 gives ·0116148:

this is for 1*l.*, giving 11·6148*l.*, or 11*l.* 12*s.* 3½*d.* for 1000*l.*, and 11,614·8*l.* to be the total premium for 1000 persons.

Question.—If the office insure a large number of persons (for the whole life or a term) at the premium p (the age being x), what will be their accumulation in n years, upon the suppositions the working of which has been shown in the example already given; it being supposed that £A is insured to every one who dies? The answer is in the following formula: for every person who, according to the tables, is alive at the end of the term of n years, there is remaining in the office, after all claims have been paid up to the end of the n years, and before the $(n+1)$th premium is paid, the sum

$$\frac{p\left\{N(x-1)-N(x+n-1)\right\}-A\left\{M(x)-M(x+n)\right\}}{D(x+n)}$$

As an example, we shall verify the accumulations of 10 years in the instance referred to; in which $p=11·6148l.$, $A=1000l.$, $x=30$, $n=10$.

N(29)	47783·19	M(30)	932·6867
N(39)	28225·55	M(40)	733·6727
	19557·64		199·0140
	×11·6148		1000
	227158·1		199014·0
	199014·0		
	28144·1		

D(40) 1555·78)28144·1(18·09002
×5075

91806·84

The answer is, that the reserve of premiums for each person of the 5075 then remaining is 18·09002*l.*, which for the whole is 91806·84*l.* The rough answer in the scheme worked out at length is 91,809*l.*

Now, this 18·09*l.*, or 18*l.* 1*s.* 10*d.*, is what is called the value of each man's policy at the expiration of the ten years; or the *very utmost* the office could afford to give him to surrender all claim, and to keep his future premiums to himself. But what is the nature of his claim on the office? Evidently this, that he has a right to make them give him a guarantee for the next ten years on payment of a premium of 11*l.* 12*s.* 3½*d.*, which could not be done at so low a rate for a new comer. Compute the premium for a person entering at 40, and insuring 1000*l.* for 10 years; that is, divide 1000 times M(40)−M(50) by N(39)−N(49), and the answer will be found to be 13·800*l.*, or 13*l.* 16*s.* If then any party aged 40, having been in the office ten years, were to put another person of the same age in his place at his own premium, he would obviously make that person a present of the difference between 11·6148*l.* and 13·800*l.*, at once (since a premium is to be paid immediately), and for nine succeeding years, if the latter should live so long. And 13·800−11·6148 is 2·1852, while an annuity of 2·1852*l.* for nine years, at the age of 40, is worth N(40)−N(49) divided by D(40) and multiplied by 2·1852, or 15·903*l.* Add to this 2·185*l.* for the immediate difference, and we get 18·088*l.*, differing only a halfpenny from 18·090*l.*, the sum which the office has in reserve. If then the person who is to take the place of the insured at 40 years of age, were to pay him an equivalent, he must, besides taking on himself the future premiums, pay the retiring member 18·090*l.*, which is therefore the value of the latter's policy. The last formula will always give the *accumulation* value of a policy, whether for the whole life or for a fixed term.

The preceding contains the most material calculations which are necessary in the management of an office, or rather, in forming an opinion on the management of an office. It is to be remembered that all which has hitherto been said supposes the rates of mortality and interest to be absolutely known and invariable, the parties to enter on their birthdays, and all claims to be adjusted at the terminations of whole years from the time of entry. We now proceed to the application.

An assurance company is a savings' bank, with a mutual understanding, presently to be noticed, between the contributors. To make out this proposition, let us suppose that A borrows money, and insures his life for the amount as a security to his creditor. For this he has to pay a premium. If life were certain, the office of the company would be to receive and invest these premiums, which would be calculated in such a manner as with their interest to amount to a sum sufficient to discharge the loan in a settled time. At the end of this time the creditor (who has been all this while receiving interest for his money from A) calls upon A to make his claim upon the office, and repay the loan with the money received. If such an office existed, life being certain, the rationale of the proceeding would be that the creditor, though tolerably confident of A's power and willingness to make any yearly payment, whether of interest or instalment, will not trust him steadily to lay by and improve yearly instalments, but requires that he should make his instalments payable to third parties, who are engaged not to return them on demand until they amount to a sum sufficient for the discharge of the debt. Such an office certainly could not exist, on account of the uncertainty of individual life. As soon however as it is known that the duration of masses of individuals can be calculated with tolerable accuracy, there is a remedy for the individual uncertainties. Let a large number of debtors, similarly situated with A, agree to be guarantees for one another; that is, let each of them pay during his life not only his own instalments, but such additional sums as will provide the means of meeting the deficits of those who die, and the savings' bank thus constructed will become an assurance-office. Of course it matters nothing whether these debtors pay their instalments to a person agreed on among themselves, or go to a company which undertakes the management of such concerns. And again, it makes no difference whether the instalments are for liquidation of debt, or to accumulate a provision for widows and children. We have taken the case of debtors, because in such a case an office looks more like a mere indemnity-office than when its contributors enter for the benefit of their families· still however, in the former case, it is evident that the premiums are partly instalments of debt, partly sums intended to make good the deficiency of the life-instalments of those who die.

Let us now suppose a company to be formed for the simple purpose of assuring lives. Their business is to invest the premiums of those who assure with them; their receipts will consist entirely of current premiums and interest on the investments of the old ones; and their outgoings will contain expenses of management, payment of claims, purchase of their own policies, and (possibly) losses by bad investment.

There is one question which is generally settled at the very outset, namely, whether the company is to be what is called mutual, proprietary, or mixed.

A mutual company is one in which the members stand bound to each other, and constitute the company themselves. In such a company no capital is, generally speaking, raised at the outset, except a small sum for necessary expenses at starting. This however is not necessarily the feature of a mutual company; for if its members choose to constitute themselves an investment company as well as an assurance company, they may, without losing their *mutual* character, require every assurer to be also a shareholder. In a mutual company the profits of course are divided among the assured.

A proprietary company is one in which a body of proprietors raise a capital and pledge it for the payment of claims, in case the premiums are not sufficient: for this security they receive, in addition to the interest of their own capital, the profits of the assurance business. It has long been proved that, with proper tables of premiums, and a fair amount of business at starting, this capital is an unnecessary security; and the only reason which could now make such an office desirable, would be the lowness of its premiums. Of course it matters nothing to the assured how they are paid, as long as they are paid; the capital may be diminished, but the assurer cares for nothing except its exhaustion before his turn comes. This must be the sole consideration with a person who is tempted by low premiums to a purely proprietary office: the nominal capital signifies nothing; it is upon the amount of assurance to which it (with the premiums) is pledged that the solvency of the office depends. Generally speaking however we believe it will be found that the purely proprietary offices have not allowed themselves to run much risk.

A mixed office is one in which there is a proprietary company, which does not take all the profits, but a share; the rest being divided among the assured. The only good effect of the capital upon the condition of the assured in such a company is this:—that the directors, having fixed capital as well as premiums, may justifiably seek for investments which a mutual company must avoid. Having the capital to make good purely commercial losses, they may perhaps attempt to get a higher rate of interest, and of course take more risk of loss; the assured, who are sharers in the whole of the profits, since the profits of premiums and profits of original capital are not distinguished, come in for their share of the extra profits of the capital. But no such attempt at gaining higher interest by secondary securities should be made until a sum sufficient (with future premiums) to meet all claims is invested in the very safest securities which the state of society offers.

There is much confusion in the ideas of many persons about interest, arising from not distinguishing between interest and other returns. The following remarks may serve to explain our meaning:—

Interest is the return which is made for the use of money, when the owner entirely relinquishes its management, and believes he has undoubted security for its return. 'Interest,' says Mr. M'Culloch, 'is nothing more than the net profit on capital.' The same author goes on to say, 'the rate of interest on each particular loan must of course vary according to the supposed solvency of the borrowers, or the degree of risk supposed to be incurred by the lender.' But here the acute writer from whom we quote, after setting out with the accurate definition of the political economist, proceeds to use the word in the common sense, in which it is no longer the net profit of capital. For this variation in the rate of interest (so called), this addition for possible insolvency, is or is meant to be only as much as will make every debtor who does pay contribute towards the bad debts of those who do not. Nothing then is netted by the in crease for suspicion of insolvency, in the long run, and one debt with another; so that, abiding by Mr. M'Culloch's definition of interest as the correct one, we should propose to call the additional sum debt insurance. To this we must add, that when a person employs his own money, as in trade or manufactures, he also gains that additional return which a borrower counts upon reserving to himself after paying the interest (and debt insurance, if any) to his creditor. This is neither interest nor debt-insurance, but is of the nature of salary, by which name it might be called. Perhaps it would be best to retain the term interest in its general loose signification, and to subdivide it, for accuracy, into pure interest or net profit, debt-insurance, and salary.

In the construction of a table of premiums, three points must be left to the judgment of the constructor, the rate of interest, the table of mortality, and the addition to be made for expenses of management and probable fluctuation, or discrepancy between the predictions of the table and the events which actually arrive. The third point would not arise if, as was once the case, the table of mortality made life much worse than the actually prevailing state of things shows it to be. Security against adverse fluctuation is thus taken in the choice of the table; and this was done by the older offices, which chose the Northampton Table;—by the Equitable, for instance. (Compare the mean duration of life in the Northampton Table with that of the Equitable experience, in MORTALITY.) But we hold decidedly by the method of choosing a true table, and augmenting the premiums given by it as a safeguard against fluctuation; and for this reason, that wrong tables are usually unequally wrong, making different errors at different ages, and thus augmenting different real premiums by different per-centages.

According to the Carlisle Table (which we prefer for the purpose), of 5642 persons alive at the age of 30, 3018 are alive at 65, whence the chance of living till the second age is $3018 \div 5642$ or $\cdot 5525$. Now by applying calculation to this question, we find that an office which would have practical certainty (thousands to one for it) that, as far as this instance is concerned, the office should not be injured by adverse departure of events from tables, must make provision for twenty-five deaths, at least, in the period above-mentioned, more than the tables predict, out of 250 persons at the commencement. And this even on the supposition that the table itself can be certainly reckoned upon as representing the law of mortality of the whole insurable population. It would be a very long process indeed to apply calculation in detail, so as to form a well supported idea of the proper amount of precaution against fluctuation; and the question is mixed up with another, to which we proceed.

The rate of interest to be assumed is an element which requires the greatest caution. It must be a rate which can actually be made, and therefore prudence requires that it should be something below that which may reasonably be looked for. To show how powerful an agent it is, we shall repeat the example already given, of the 5642 insurers for twenty years, on the supposition that the office which charges as for 3 per cent. finds itself able to make $3\frac{1}{2}$ per cent.

It thus appears that the office leaves off with an accumu- lation of 15,441*l.* nearly; and if it be lucky during the fi[illegible] years, it may be said to be safe (as we find) against a[illegible] fluctuation for which there is an even chance, by the increase of interest alone.

Take what amount of precaution we may, an office must, at first starting, depend upon something either of capital or guarantee. Even a mutual office must raise something at the outset. Tables must be constructed with very large additions to the calculated premiums, which are to meet the very earliest contingencies alone; indeed it is difficult to say what addition would be too large. But this point it is unnecessary to insist on, since we can hardly suppose it possible that any set of men would found an office with no resource except premiums from the very commencement. Supposing proper precautions to be taken, we imagine that an addition of 25 per cent. to premiums calculated from the Carlisle Tables at 3 per cent. per annum, is sufficient to place a mutual office upon a sound footing, and to give a very great prospect of a return in the shape of what is called profit. In never has been found that an office charging at this rate has been without surplus of some kind.

This surplus has been called by the inaccurate name of profit, whereas it is really that part of the security against fluctuation of interest and mortality which has been found to be unnecessary. In mutual offices it is to be returned to the assured in an equitable manner; in purely proprietary offices it is really profit to the proprietors, whose capital has yielded them the ordinary interest, since by hypothesis none of it has been necessary to meet claims, and they therefore share among themselves the residue of the premiums. It is impossible to avoid this surplus in a well-constituted office, for the mathematical line which separates surplus from deficiency cannot be expected to be attained, so that those who would not have the latter must take care to have the former. It is usual among the offices to adopt a plan for increasing this surplus, which we will now describe.

Two rates of premiums are adopted, the one less than the other. Those who pay the higher rate are to have a share of the surplus; those who pay the lower rate have nothing but the nominal sum for which they assure. If the table of lower rates yield a surplus (which it is supposed it will do), that surplus goes to augment the final receipts of those who assure for profits. This scheme may be very well practised by a proprietary company, or by an old mutual company, but whether it is a good plan for a young mutual company to adopt, may be a question.

The public has been much misled by a notion that assurance companies must accumulate large profits, and the Equitable has been constantly cited as the proof. Now all who would form an opinion on this subject must remember that the circumstances of the Equitable are very peculiar. It realized large accumulations, in the first instance, by an excess of caution, commendable at the time, but since proved to be unnecessary. Of late years, newly assured parties are allowed to share in these accumulations, on condition that they are first assured in the office for a large number of years, taking the chance of receiving less than their premiums are really worth. This however is not the question here; we merely stop to remind the reader who is disposed to form a general opinion about offices, because the executors of A, B, and C receive two or three times the sum for which those persons were nominally insured, that this only happens because D, E, and F, who died during the days of a caution which has since been shown to be unnecessary, did not get their share of the then existing surplus.

The expenses of management are relatively trifling when the office has obtained a large amount of business, but they bear heavily on young offices during the first years. The most formidable expense of all, at least to many, must be that of advertising; and this is a point on which it is well worth while to dwell.

When a tradesman advertises, he sacrifices, in the expense of the advertisement, a part of the profit which he would have had if his customers would have come without the advertisement. The only question for him is, whether it is better to turn his money more quickly with a smaller profit, or to wait longer and make a larger one; and that the first is found to be the best plan in many cases, the frequency of advertisements fully proves. It is purely a question for the tradesman to settle for himself, and the customer has no interest in the matter. But in the case of the assurance office, the matter is very different. If, in looking at a tradesman's advertisement, we should ask, *Who pays for this advertisement?* the answer would be easy; it is the tradesman himself, out of his own profits. But if we ask the same question with reference to the advertisement of an assurance company, the answer must be that it is paid out of the premiums of the assured. When the company is proprietary, the case is so far like that of the tradesman that it is paid out of surplus of premiums, which the assured will never get in any case; but when the company is one which is to return all or part of the profits to the assured, the latter may be certain that, *ceteris paribus*, his share will be larger the less the company advertises. There is a set-off certainly of this kind; the more business a company gets, the less heavily do the necessary charges of management bear upon the assured; so that, up to a certain point, advertising may be a beneficial outlay, since the necessary expenses of management, plus those of advertising, may be less when divided among the assured before the advertisement together with those who are brought by the advertisement, than the first of the former alone would be when divided among the first of the latter alone. But this must have a limit; for if not, the older offices would have continued their advertisements daily up to the present time: and even with regard to the proprietary company, which might perhaps consistently advertise a great deal more than the mutual company, there is yet this to be said, that a great quantity of advertising shows their premiums to be very profitable, for how else could they do it? and in such a company there is no return to the assured.

Again, when the advertisement is of this kind that it invites the public attention to lower rates of premiums than are charged elsewhere, and when such advertisement is very frequently repeated, the prudent assurer will naturally be disposed to ask how, if the premiums be so much reduced, this heavy expense of advertising is to be borne. When a tradesman advertises cheaper goods than his neighbours, we know that he relies upon making a very small profit upon his capital ten times in a year, instead of a larger profit two or three times. One per cent. is a small profit, but one per cent. per diem looks very like 313 per cent. per annum, excluding Sundays. But the assurance-office is of a very different kind of business: imagine a savings' bank advertising every day in the newspapers that it is a savings' bank, and will receive deposits; it is very clear that from and after the point at which the deposits so obtained relieve the necessary and constant charge of management, as above described, all advertisement is anything but beneficial to depositors. When therefore an assurer is induced by frequently repeated advertisements at last to deliberate upon going to an office, let him remember that this quantity of advertisement bodes him no good in itself, and let him look out as to whether there is any countervailing advantage: if he can find none, let him, for his own sake, take a little trouble to search out an office which advertises less, and perhaps he will find it performs more. It is very easy to spend five thousand a year in advertising. Our limits will not allow us to speak of the *commission* (so called) which most offices give to those who bring them business. This practice has been frequently attacked, and very feebly defended. All we say to those who assure is, insist upon having it for yourselves, and do not come worse off than your own agents would do, if you employed any. (On this point see the *Dublin Review* for August, 1840.)

The division of the profits (so called), that is, the method of returning to the assured the surplus of their premiums, with their accumulations of interest, has been the subject of much discussion. Offices have adopted very different modes of proceeding in this respect: some keep this surplus for the older members; some divide it by addition to the policies made annually, or at periods of five, seven, or ten years; some apply it in reduction of premiums as fast as its value is ascertained. Most, or all, of the methods followed by the offices seem to be fair, that is, they make the chance of surplus the same for one member as for another, at least of those who enter at the same age: if there be anything inequitable, it arises when the premiums are disproportioned at different ages, so that the surplus is differently levied upon different classes of members. Leaving this however, we shall proceed to inquire what may be the probable amount of surplus in an office charging premiums made from the Carlisle Table at 3 per cent., with 25 per cent. added, taking the most favourable suppositions. Let the mortality be no greater than that in the table, let there be no expenses of management, and let the office be able to net 4 per cent. compound interest. Then we find that the office is in reality charging for the following sums, under the name of 100*l.*; that is to say, all the preceding suppositions being correct, the office might undertake to pay the following sums instead of the 100*l.* minimum which they do really guarantee. The sums are only roughly put down, within a pound or thereabouts.

Age.	£.	Age.	£.	Age.	£.
20	166	35	157	50	148
25	163	40	155	55	144
30	160	45	152	60	141

There is an inequality here which arises from the supposition of the office gaining a greater interest than was supposed in its tables; and it is obvious that the young assurer must make that excess of interest more beneficial to the office than the old one. Consequently where an office realises some of its surplus by excess of interest, there is equity in giving the one who entered young somewhat more than the one who entered later in life. But this has never been the principle on which any office made its divisions: some distinguish those who have been a long time in the office from those who enter newly, and the greater number of those so distinguished must have entered younger than the greater number of the undistinguished; but the intention of the office has no reference to age at entry, but only to time of continuance.

The true method of determining the actually existing surplus must have some connection with that which would be followed if the company wished to break up, dividing its assets fairly among the assured. Let us suppose the stock of the company, all that it actually has or could realise, to be worth half a million, and that the premiums which the existing contributors would pay are valued at another half million, while the claims of these contributors are valued at 750,000*l.* Consequently there is a million to meet 750,000*l.* or 133⅓*l.* can be given for 100*l.* Now suppose that instead of breaking up, the office wishes to know how much it can afford to give in payment of a claim of 100*l.* The first question is, how did this surplus arise?—the office has in possession or prospect 250,000*l.* more than what is estimated to be absolutely necessary. If this surplus really arose out of the natural operation of the premiums, &c., it is clear that the office is now in a condition to pay 133⅓*l.* for 100*l.* Supposing this done for the current year, the valuation of the next year will point out what alteration, if any, is necessary. This mode of division is the safest in the long run, because any excess in one year will be compensated in future years. Another mode is to divide the surplus of 250,000*l.* among the existing policies, in equitable proportions; and a third is to consider it as advance of premium on the part of the existing contributors, and to diminish their future premiums as if they had actually made such advance. It is not however our present purpose to extend an article already longer than we had intended it to be, by entering into a lengthened explanation on this point.

We shall end by a table of the various assurance offices which are actually doing business in London, as complete as our means of knowledge enable us to make it: we cannot answer for its being perfectly complete. But, the present article being intended for the assurer, and not for the office, we make the following remark.

The benefits of life assurance (which is in reality a large combination of small sums for the purpose of beneficial investment, with a contract among those who invest that the inequalities of life shall be compensated so that those who do not live their average time shall be sharers in the good fortune of those who exceed it) and the moral considerations which should induce every friend of his species to promote and extend it, are of course not the particular motives which actuate the founders of such offices, though no doubt they have them in the same degree as others. To bring business to a particular office becomes their interest and their object; and every possible mode of investment has been held out to engage the attention and suit the particular objects of the assurer. To this of course, in general, we do not object: for instance, when a company proposes twenty different kinds of assurances, it is enough for the public that the terms of each kind are sufficiently high, and yet not too high. But it sometimes happens that among the proposals which are held out for the assurer's acceptance, are to be found some which altogether militate against the moral principles of assurance: these are prudence, foresight, and present self-denial for the attainment of ultimate prosperity and of present security against the chances of life. When an office announces that it is willing to leave a part of the premium in the assurer's hands, on his paying interest for it in advance, the office in the meanwhile holding the policy as a security,—what is it but enticing a person to assure for more than he can afford to do, and to borrow money for the purpose of paying the premiums? The office may, with caution, make itself secure; but it throws upon the customer the strong probability of future disappointment. When the time comes for thinking of the repayment of the advances which the office has virtually made, the assurer will frequently find himself obliged to sell that policy to the office which he had counted upon for the benefit of his family. Now out of the purchase money must be deducted the sums in arrear to the office (upon which interest has always been paid in advance); and when the assurer comes to put his balance against what he has actually paid, he will see that he never did a more imprudent act. The office is not to blame for anything but having thrown the original offer in his way; they have only lent him money on the same terms as they would have lent it to others; and they may say, and truly, that it was his own fault if he engaged in an imprudent speculation. But is it not then a fault to entice others to imprudence, knowing how much more easily men are induced to be imprudent than to be prudent?

REVERSION OF SERIES. In the nomenclature of mathematics, which is far from being consistent with itself, the words *reversion* and *inversion* are sometimes confounded. Thus the term by which we describe the square root, as connected with the square, is, that each is an INVERSE process to the other; but if y be a given series of powers of x, the determination of x in a series of functions of y is not called inversion, but reversion. Various points connected with reversion (to keep the common term) will be met with in TAYLOR'S THEOREM and SERIES; the present article is meant purely for reference upon the most usual case of the problem, which is not sufficiently developed in elementary works; that is, enough of the result for reference is not put down.

The problem is as follows:—Given $y=ax+bx^2+cx^3+ex^4+fx^5+\ldots$; required x in a series of the form $Ay-By^2+Cy^3-Ey^4+\ldots$. It will be proper first to put down the coefficients in connection with the exponents to which they belong, as follows:—

1	2	3	4	5	6	7	8	9	10	11
a	b	c	e	f	g	h	k	l	m	n
A	B	C	E	F	G	H	K	L	M	N

It will be convenient, instead of writing the resulting series $Ay-By^2+\ldots\ldots$, to let it be $Aa^{-1}y-Ba^{-3}y^2+Ca^{-6}y^3-Ea^{-7}y^4+Fa^{-9}y^5-Ga^{-11}y^6+Ha^{-13}y^7-Ka^{-15}y^8+La^{-17}y^9-Ma^{-19}y^{10}+Na^{-21}y^{11}-\ldots\ldots$ We then have

$A=1$

$B=b$

$C=2b^2-ac$

$E=5b^3-5abc+a^2e$

$F=14b^4-21ab^2c+3a^2(2be+c^2)-a^3f$

$G=42b^5-84ab^3c+28a^2(b^2e+bc^2)-7a^3(bf+ce)+a^4g$

$H=132b^6-330ab^4c+60a^2(2b^3e+3b^2c^2)-12a^3(3b^2f+6bce+c^3)+4a^4(2bg+2cf+e^2)-a^5h$

$K=429b^7-1287ab^5c+495a^2(b^4e+2b^3c^2)-165a^3(b^3f+3b^2ce+bc^3)+45a(b^2g+2bcf+be^2+c^2e)-9a^5(bh+cg+ef)+a^6k$

$L=1430b^8-5005ab^6c+1001a^2(2b^5e+5b^4c^2)-715a^3(b^4f+4b^3ce+2b^2c^3)+55a^4(4b^3g+12b^2cf+6b^2e^2+12bc^2e+c^4)-55a^5(b^2h+2bcg+2bef+c^2f+ce^2)+5a^6(2bk+2ch+2eg+f^2)-a^7l$

We have given these coefficients to an extent which many will think useless, and in fact it will not often be necessary to employ all that are here given. But we have two objects in view: first, to enable those who want these coefficients to refer to them; secondly, to point out the great advantage of some methods which are never given in elementary works, and are not so much known and practised as methods of such utility and power should be.

The usual way of obtaining these results is to take the series $x=Aa^{-1}y-Ba^{-3}y^2+\ldots\ldots$, and in it to substitute the value of y, namely, $ax+bx^2+\ldots$. This would give

$$x=\frac{A}{a}(ax+bx^2+\ldots)-\frac{B}{a^3}(ax+bx^2+\ldots)^2+\ldots,$$

the two sides of which equation must be identical; giving

$$A=1,\quad A\frac{b}{a}-B\frac{1}{a}=0,\quad\text{or } B=b;$$

$$\frac{A}{a}c-\frac{2B}{a^2}b+\frac{C}{a^2}=0,\quad\text{or } C=2b^2-ac,$$

and so on; but this process would become intolerably tedious and liable to error after a few steps; that which we have followed in forming the preceding coefficients [TAYLOR'S THEOREM] would have enabled us with comparatively little difficulty and small risk of error to double their number. It also gives the law of the coefficients, which is as follows:—

1. What sort of terms enter into M, the coefficient of y^{10}? Write down every way in which $2(10-1)$, or 18, can be made up of $10-1$, or 9, numbers, and, taking the letters

belonging to these numbers from the table, we have the literal parts of the different terms of the coefficients. Thus—

18 is made up of the nine numbers 1, 1, 1, 1, 2, 2, 2, 2, 6, the letters of which are $a, a, a, a, b, b, b, b, g$: accordingly, $a^4 b^4 g$ is the literal part of one of the terms of M. And similarly for every other combination of nine numbers which makes 18.

2. What is the coefficient of any given term? Say that y^n is the power to which the term belongs, and that $a^{\alpha} b^{\beta} c^{\gamma} \dots$ is the literal part of it. The coefficient required is as follows:—

$$\frac{(n+1)\ (n+2)\dots\dots(2n-\alpha-2)}{(1.2.3\dots\beta)\ (1.2.3\dots\gamma)\ (1.2.3\dots\delta)\dots}$$

Thus, to verify the numerical coefficient of $a^6c^2e^2$ in N, the coefficient of y^{11}, we must calculate ($n=11$, $\alpha=6$, $2n-\alpha-2=14$),

$$\frac{12\ .\ 13\ .\ 14}{(1\ .2)\ (1\ .2)}, \text{ which is } 6\,.\,13\,.\,7, \text{ or } 546,$$

and 182×3, the coefficient in the table, is also 546.

2. The sign of any term is positive or negative according as the power of a which it contains is even or odd.

We may thus verify any one term, and the coefficients may be sufficiently verified, as to typographical* correctness, by remembering, that if $a=b=c=\&c.=1$, we should have $A=B=C=\&c.=1$; for $y=x+x^2+x^3+\dots$ gives $x=y-y^2+y^3-\dots$. The result of the use of the preceding table, distinguishing the positive from the negative parts, is

$$x=y-y^2+(2-1)\,y^3-(6-5)\,y^4+(23-22)\,y^5-(99-98)\,y^6$$
$$+(452-451)\,y^7-(2140-2139)\,y^8+(10397-10396)\,y^9$$
$$-(51525-51524)\,y^{10}+(259430-259429)\,y^{11}.$$

The preceding is a particular case of the following general problem, which frequently occurs, and is very complicated in its details. Given $y^m=ax^m+bx^{m+1}+cx^{m+2}+ex^{m+3}+fx^{m+4}+\dots$; required a series for x in powers of y. Let it be assumed that

$$x=$$
$$A\frac{y}{a^n}-B\frac{y^2}{a^{2n+1}}+C\frac{y^3}{a^{3n+2}}-E\frac{y^4}{a^{4n+3}}+F\frac{y^5}{a^{5n+4}}-\dots\dots$$

n being $1:m$. Then $A=1$, $B=nb$:

$$C=n\,\frac{3n+1}{2}\,b^2-n\,ac$$

$$E=n\,\frac{4n+1}{2}\,\frac{4n+2}{3}\,b^3-n\,\frac{4n+1}{2}\,2abc+n\,a^2e$$

$$F=n\,\frac{5n+1}{2}\,\frac{5n+2}{3}\,\frac{5n+3}{4}\,b^4-n\,\frac{5n+1}{2}\,\frac{5n+2}{3}\,3ab^2c$$
$$+n\,\frac{5n+1}{2}\,a^2\,(2be+c^2)-n\,a^3f$$

Methods of obtaining all these series are given in TAYLOR'S THEOREM.

REVERSION. 'Reversion of land is a certain estate remaining in the lessor or donor, after the particular estate and possession conveyed to another by lease for life, for years, or gift in tail. And it is called a reversion in respect of the possession separated from it; so that he that hath the one, hath not the other at the same time, for being in one body together, there cannot be said a reversion, because by the uniting, the one of them is drowned in the other. And so the reversion of land is the land itself when it falleth.' (*Termes de la Ley.*) Thus if a man seised in fee simple conveys lands to A for life, or in tail, he retains the reversion in fee simple. The distinction between a remainder and a reversion has been explained in REMAINDER. In all cases where the owner of land or the person who has an estate in land, grants part only of his estate, he has a reversion; and as the grantee holds of him, there is tenure between them, and the grantor has a seignory by virtue of having a reversion. When a man grants all his estate to another, or grants a particular estate to A, and various remainders over, remainder to F in fee, he has no reversion left, and therefore he has no seignory since the passing of the statute of Quia Emptores. The remainder-men also who precede the remainder-man in fee, do not hold of such remainder-man, but of the lord of the fee of whom the original owner held. The word reversion is often used inaccurately, and it is sometimes necessary to recur to its strict legal signification.

* Should there be any error, it will be mentioned in SERIES.

Before the passing of the statute De Donis, if a man seised in fee simple granted his lands to a man and the heirs of his body, he had no reversion, for the grantee was considered to have a conditional fee. But since this statute, an estate to a man and the heirs of his body has always been considered to be a particular estate.

If a man grants a lease of lands in possession, at common law, he has no reversion until the lessee enters by virtue of his lease, for the lessee has no estate until he enters; but if the term of years is created under the Statute of Uses, as by bargain and sale, the lessee has a vested estate by virtue of the statute, without entering on the land, and consequently the lessor has a reversion. It is said that a reversion cannot be created by deed or other assurance, but arises from construction of law. This means that a reversion is not created by the act of the party who conveys part of his estate, but is a legal consequence of his acts. If a man seised in fee simple limits his estate to another for life or in tail, remainder to himself in fee or to his own right heirs, he has not a remainder, but a reversion. Yet by a recent statute (3 and 4 Wm. IV., c. 106) the effect of such a limitation is to vest such remainder in fee in the settlor by *purchase*, and he is not to be considered to be entitled to it as his former estate or part thereof.

A reversion is a vested estate, which may be granted or conveyed, and charged like an estate in possession; and in some cases the reversioner in fee may bring an action, as well as the tenant in possession, for an injury to his inheritance.

Fealty is an inseparable incident to a reversion. There may or may not be a rent reserved, but fealty is always due from the owner of the particular estate to the reversioner, and it cannot be separated from the reversion, though the rent, if there is one reserved, may be separated from it. [RENT.] Reversions which are expectant on estates for years are subject to dower and courtesy; but this is not the case with reversions expectant on a freehold estate.

By a recent act (3 and 4 Wm. IV., c. 104), reversionary estates or interests in lands, tenements, and hereditaments, corporeal and incorporeal, are assets to be administered in courts of equity for the payment of a person's debts both on simple contract and on specialty, when such person shall not by his last will have charged such estates or interests with or devised them subject to the payment of his debts.

When a reversion expectant on an estate tail comes into possession, it is liable to the leases made by those who were at any time entitled to the reversion, and to the covenants contained in such leases. All particular estates, except an estate tail, are subject to merge in the reversion, when the particular estate and the reversion are united in the same person. Formerly when an estate tail was converted into a base fee, and the remainder or reversion in fee in the same lands became united in the same person, the base fee was subject to merger in the reversion: but by the 39th section of 3 and 4 Wm. IV., c. 74, when such union takes place, and there shall be no intermediate estate between the base fee and the remainder or reversion, 'the base fee shall not merge, but shall be *ipso facto* enlarged into as large an estate as the tenant in tail, with the consent of the protector, if any, might have created by any disposition under this act, if such remainder or reversion had been vested in any other person.' Before this statute, when a base fee thus merged in the reversion, the reversion became an estate in possession, and liable to all the leases and charges of those who had at any time been entitled to it.

REVETMENT, in permanent fortification, is a wall of brick or stone retaining the mass of earth which constitutes the rampart, generally on the exterior side only, or retaining the earth which forms the opposite side of the ditch. The exterior faces of these walls are considered as the scarp and counterscarp of the ditch.

In and before the time of Vauban the scarp revetments were raised from the bottom of the ditch to the top of the parapet; but the part which was visible above the glacis being destroyed by the enemy's artillery, and the parapet in consequence partly ruined soon after the commencement of the siege, that engineer in most of his works raised his revetments no higher than the level of the crest of the glacis, or about 7 feet above the natural ground; the exterior of the parapet was then left at such an inclination to the horizon (45° in general) that the earth would support itself. The ditch of a fortress being about 18 feet deep, the height of the scarp revetment was consequently 25 feet, and this was considered sufficient to afford security against the danger of having the rampart escaladed. At present it is recommended that the main ditch should be 24 feet deep, and in this case the scarp revetment is above 30 feet high. In constructing the fortifications of Neuf Brisac, Vauban made the revetments of the scarps both of the enceinte and of the reduit of the ravelin, as high as the top of the parapet; but these works being covered by the counterguard or the ravelin, their revetments would be unseen by the enemy at a distance, and therefore not liable to the objection above mentioned.

The form usually given in profile to revetments of masonry may be seen at M and N, *fig.* 2, Bastion; the first is the revetment of the counterscarp, and the other that of the scarp. The rectangular parts are sections through the counterforts or buttresses which are built up with the walls in order to strengthen them, at intervals of about 15 feet from each other. Scarp revetments, whose tops are as high or higher than the crest of the glacis, are called full revetments; while such as are no higher than the level of the natural ground are called demi-revetments.

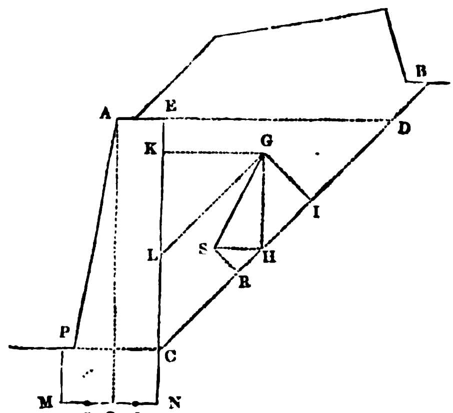
In order that the revetment might most effectually resist the pressure of the earth which it is to support, Vauban gave to the exterior face of the wall a slope, whose horizontal breadth was equal to one-fifth of the height; this was subsequently reduced to one-sixth, and not long since there were thought to be some advantages in making the face vertical.

In laying the foundations of revetments in defective soils, the same methods are used as in the construction of civil edifices; and in all cases the courses of stones or bricks are laid obliquely to the horizon, inclining down towards the part under the earth which is to be supported, in order that the pressure of the latter may be more directly resisted. But as the bed-joints of brickwork when so disposed allow the rain to penetrate, and the seeds of grass to lodge in them, it is thought that the wall is more speedily degraded when so built than when the courses are laid horizontally; therefore in order to unite the advantages of direct resistance and durability, it is customary to place the courses obliquely, but to lay one row of bricks in each course at the face of the wall in a horizontal position.

The exterior and interior faces of the revetment, or retaining wall of a dock, have in a vertical section the form of concentric arcs of circles, with their convexities towards the land; and this form is given them that the stones may be able to resist the hydrostatical pressure of any water which, when the dock is full, may get behind the wall, and which may be prevented from escaping when the dock is made dry.

Some of the ramparts of Coehorn, and all of those which Carnot proposed for his fortresses, are formed of earth unsupported by revetments; and even the opposite side of the ditch, instead of being faced with a steep wall, is by the latter engineer cut with a gentle slope from the level of the natural ground to the bottom of the ditch. But the fortifications of Coehorn are provided with wet ditches, which prevent the besiegers from getting to the foot of the rampart by surprise; and in those of Carnot a high detached wall covered by a counterguard of earth puts it out of the power of the enemy, while that wall stands, to get across the ditch. Without such obstacles the unreveted rampart would afford great facilities to the enemy in an effort to carry the fortress by assault. Its exterior slope must form at most an angle of 45° with the horizon, that the earth may support itself, and consequently it may be easily ascended; and any palisades or other impediments which the defenders might place on it would soon be displaced or destroyed by the batteries of the enemy. Besides these evils, the exterior slope, from its breadth, occupies a great portion of ground; it consequently obliges the engineer to contract the space enclosed within the works, and thus to sacrifice in some measure the convenience both of the inhabitants and the garrison.

In order to investigate the conditions of stability in revetment walls, let EBC be a vertical section through the mass of earth retained by the wall; BC being the slope which earth is supposed to assume when unsupported, and let AEMN be a section of the wall, PC being the level of the bottom of the ditch, and MN being the bottom of the foundation. Imagine G to be the centre of gravity of the section ECB; draw GL parallel to BC and GK parallel to the horizon: then, by the resolution of forces, KL and GK will have to one another the same proportion that the weight of the unsupported prism of earth (of any thickness) bears to its horizontal pressure. Let W be that weight; then $\frac{KG}{KL}$ will express that pressure, and $\frac{KG}{KL}.W.KN$ will be the momentum or power by which the earth tends to overturn the wall about M.



Imagine the vertical line AQ to be drawn; then the form and dimensions of the part AMQ of the wall are known, and let it be required to find the breadth QN of the rectangular part AN, so that the resistance of the whole shall be equal to the momentum of the supported earth. Suppose the centre of gravity of AMQ to be found, and let it be vertically over a. The centre of gravity of the rectangular part is vertically over b, the middle of QN; and let Qb be represented by x. Then if g be the specific gravity of the wall, we have by mechanics, $AMQ\,.\,Ma\,.\,g+AQ\,.\,Mb\,.\,g\,.\,x$ for the resistance of the wall; consequently equating this expression with the above momentum of the earth, the value of x, and therefore of QN, can be found. But great uncertainty exists respecting the position of the line of rupture BC, from our ignorance of the allowance to be made for the effect of friction on the tendency of the earth to slide downwards. Experiments have led to the opinion that this effect is equal to half the pressure of the earth perpendicularly upon the inclined plane which it would assume if unsupported; and that value is frequently adopted.

In order to find the magnitude which the triangle EDC should have when the supported earth exerts the greatest pressure against the wall, the following process may be used; the earth above AD being at present, for simplicity, supposed to be removed. Imagine G to be the centre of gravity of that triangle, and the vertical line GH to be drawn; then GH may represent the weight of the unsupported earth, and let it be resolved into the pressures represented by GI and IH, the former perpendicular to the slope, and the latter coincident with it. Imagine HS to be drawn to represent the re-action of the wall AMN, and let it be resolved into the forces represented by SR and RH, perpendicular to and coincident with the slope, respectively. Then, IH representing the force with which the prism of earth would tend, if without friction, to slide down DC, RH represents the re-action by which the wall resists that force; while GI and SR represent the pressure and reaction perpendicular to DC. Consequently, the friction being supposed to be equal to half the pressure, we have $\frac{1}{2}(GI+SR)$ for the effect of friction; and in the case of equilibrium, $IH=RH+\frac{1}{2}(GI+SR)$.

Let $EC=h$, $ED=z$, $HS=p$, and let g be the specific gravity of the earth; then $\frac{hgz}{2}$ expresses the weight of the prism whose section is EDC, and whose thickness is unity, and which was represented by GH; and the triangles GIH, HSR being similar to ECD, we get by proportions

$$IH=\frac{h^2gz}{2CD},\ HR=\frac{pz}{CD},\ GI=\frac{hgz^2}{2CD},\text{ and } SR=\frac{ph}{CD}.$$

These values being substituted in the above equation, the value of the pressure HS or p will be found to be $\frac{h}{2} g \cdot \frac{2hz-z^2}{2z+h}$. Now this quantity is to be a maximum; therefore making its differential relatively to z equal to zero, the value of z will be found to be $\cdot 618h$; whence $p = \cdot 1908gh^2$. If this equation be differentiated relatively to h, the result will express the horizontal pressure against an elementary portion of the wall at a variable height (which represent by h) above C: therefore multiplying by h and integrating, we get $\cdot 1272gh^3$ for the whole force exerted by the earth to overturn about M a wall whose height EC is represented by h, when that force is a maximum. When there is a parapet above AD, its weight, expressed by the product of the area of the section multiplied by g must be added to the above expression for the weight of the prism EDC in the preceding investigation, in order to obtain the value of the expression which is represented by GH.

Instead of making a revetment in the form of a simple wall, it is customary to build buttresses or counterforts at intervals from each other on the side next to the supported earth; consequently the thickness of the wall itself may be rather less than that which would result from the above equation. In order to determine it, if we assume, for example, that the distance from the centre of one counterfort to that of the next is fifteen feet, the area of a horizontal section fifteen feet long and taken at the mean height of the wall, if the face has a slope, together with the area of the like section through the two half-counterforts, may be equal to the area of a section of the simple wall (of the same length) as determined by the above investigation; then deducting one-fifth of that quantity for the two half-counterforts, the remainder divided by 15 will give the required breadth of a horizontal section at the part between the counterforts. It should be observed however that the thickness of a brick revetment which is to resist the fire of a battering-train should not be less than seven or eight feet. It is usual to make the depth of a counterfort equal to the mean breadth of the wall; and to give it greater thickness at the part which joins the wall than at the other extremity.

Counterforts serve in part as props to keep the wall from inclining in consequence of partial compressions in the cement; but chiefly by extending the breadth of the base at intervals they increase, at the places where they are formed, the length of the arm of the lever by which the weight of the wall resists the lateral pressure of the earth. The usual connection of the bricks or stones in the wall with those of the counterforts allows this advantage to be extended in nearly an equal degree to the parts which are situated between the counterforts. But in order that the connection may be more complete, it has been recommended to connect the tails of every two counterforts by a wall curved on the plan, and having the convex side towards the earth which is to be retained. Again, the nearest sides of every two counterforts have occasionally been connected by two or more arches, one above another; by which means the mass of retained earth is in part supported, and the lateral pressure of the whole is diminished.

Revetments in which the counterforts are connected in either of those ways are said to be counter-arched; and it is recommended that arches of the latter kind should be formed in the mass of the parapet above the cordon of the scarp. It is also recommended that the masonry of the arches in the rampart should be but slightly connected with that of the revetment wall; since then the greater part of the rampart and parapet will remain supported by the arches even after the revetment has been demolished by the artillery of the besiegers.

REVOLUTION. This well known term is applied in astronomy to the manner in which a detached body moves round another, as a planet round the sun; but the motion of connected particles of matter round an axis, such as the diurnal revolution of a planet, is more usually called ROTATION.

In pure mathematics the word revolution is applied to the angle moved over by a line which revolves round a point from any one position to that position again; it is therefore a synonym for four right angles.

REVOLUTION OF 1688. [WILLIAM III.]

REY, JEAN, a French physician, was a native of Bugue on the Dordogne. In 1630 he published, at Bazas, a town about 30 miles south-east of Bordeaux, a book under the following title: 'Essays de Jean Rey, Docteur en Médécine, sur la Recherche de la Cause pour laquelle l'Estain et le Plomb augmentent de poids quand on les calcine.' To this inquiry it appears that Rey was incited by a letter from Sieur Brun, prefixed to the work, as the cause 'qui a donné sujet au présent discours.' M. Brun states that on subjecting melted tin to the air in a pot, he found that it increased very considerably in weight, and applied to Rey to explain so unexpected a fact, and he afterwards made a similar experiment with lead, and with a corresponding result.

Rey, after refuting all the different explanations of this increase of weight which had been advanced, says, in his 16th essay, 'I have now made the preparation, laid as it were the foundation of my answer to the Sieur Brun's demand, namely, that having put *two pounds six ounces* of fine English tin into an iron vessel, and heated it strongly in open air for six hours, stirring it continually, without having added anything, he obtained *two pounds thirteen ounces* of a white calx, which at first occasioned him great surprise, and the desire to ascertain whence these seven ounces of increase were derived; now, to augment the difficulty, I say that we must not only inquire whence these seven ounces are derived, but moreover, whence that which has replaced the loss of weight necessarily arising from the enlargement of the volume of the tin by its conversion into calx, and from the vapours and exhalations that have evaporated. To this question then, resting on the foundations that I have laid, I answer, and proudly maintain, that this increase of weight comes from the air, thickened and made heavy, and in some measure rendered adhesive on the vessel, by the violent and long-continued heat of the furnace, which air mixes with the calx (its union being assisted by the continual stirring), and attaches itself to its smallest particles, no otherwise than as water when sand is thrown into it makes it heavier by moistening it and adhering to its smallest grains.'

In the 11th and subsequent volumes of the Royal Institution Journal, Mr. Children has given translations of various essays of Rey, which are extremely well worth perusal by those who are curious in the history of chemical discovery. We have already mentioned that Rey's work first appeared in 1630, and it was greatly neglected till 1777, when a new edition appeared, and it is remarked by Mr. Children that the 'copies of this reprint disappeared in a very sudden and remarkable manner,' and the fact has led to a suspicion that it was effected by Lavoisier and his friends, to avoid the imputation of plagiarism in his celebrated work which appeared about three years afterwards.

Mr. Children and Dr. Thomson however are both inclined to give full credit to the assertion made by Lavoisier that he knew nothing of Rey's Essays when he originally undertook his experiments.

REYNOLDS, SIR JOSHUA, born at Plympton, July 16, 1723, of an antient family of the county of Devon, was the son of the Rev. Samuel Reynolds, rector of Plympton St. Mary, and master of the free grammar-school there. This celebrated painter was originally intended by his father for the medical profession, but he manifested when still a child so great a taste for drawing, that his father was induced to abandon his intention. Reynolds's natural inclination to the arts was much strengthened by studying the Jesuits' Perspective, but was finally confirmed, and became a passion, through the perusal of Richardson's treatise on painting, and he was from that time resolved to become a painter. He was accordingly, in 1741, in his eighteenth year, placed by his father for four years with Hudson, the principal portrait-painter of that time. The plan of instruction adopted by this painter, that of setting his pupil to copy Guercino's drawings, had a decided influence upon Reynolds's future taste, and was unquestionably one of the principal causes of the difficulty which he ever after experienced when drawing from the life, and especially from the naked figure. Reynolds and his master did not agree, and they separated in an unfriendly manner when half the period of the engagement had expired. Reynolds returned into Devonshire, and upon this slight foundation commenced his career as a portrait-painter, at Plymouth Dock. He was fortunate in obtaining the patronage of Lord Mount Edgecombe, whose influence was of the utmost service to him in procuring him introductions to the most distinguished naval officers of that port, amongst whom was Captain (afterwards Admiral Lord) Keppel, a connection that proved subsequently most valuable to him. Many naval and military officers sat to him for their portraits at this time; and he exhibited at this early stage of his career decided traces of his future style. The portraits of William Gandy of Exeter, which he greatly admired for their bold and effective manner, tended not a little to confirm that taste which his previous education from Guercino was so well calculated to engender. After the death of his father, in 1746, Reynolds came to London, where he took apartments and commenced practice in St. Martin's Lane, then a favourite quarter with painters. In 1749 he accompanied Commodore Keppel as that officer's guest, in the Centurion, to the Mediterranean; and after a delay of two months at Minorca, where he resided with the governor, General Blakeney, and during which time he painted the portraits of several naval and military officers, he embarked for Leghorn, and prosecuted his journey to Rome.

Perhaps, with the exception of Flaxman, no English artist of eminence ever took so much experience with him to Rome as Reynolds did; yet, when he first saw the grand works of Raphael in the Vatican, he was greatly disappointed. However, as he himself has recorded, he did not for a moment suppose that Raphael owed his reputation to the ignorance or caprice of mankind, but he felt his own ignorance, and stood abashed. All the undigested notions of excellence which he had brought with him from England were to be eradicated from his mind; he felt that he had originally formed a false opinion of the perfection of art; 'and that if those works had really been what he expected, they would have contained beauties superficial and alluring, but by no means such as would have entitled them to the great reputation which they have so long and so justly obtained.'

Notwithstanding this candid confession, the conviction seems to have had little or no influence upon his own manner in after-life, for he never possessed one single quality in common with Raphael.

Reynolds never made a practice of copying pictures or taking sketches of whole compositions, as is the habit with many young painters. He very properly considered copying a 'delusive kind of industry;' yet he was in the habit of selecting parts of compositions which were of striking excellence, or from an attentive study of which he imagined he should derive substantial benefit. It was in studying the various great works in the Vatican, particularly those of Michael Angelo and Raphael, that he contracted a severe cold which caused a deafness for the remainder of his life. From Rome he went to Florence, Bologna, Parma, Modena, Milan, Padua, and Venice, where he lodged with Zuccarelli, the landscape painter. The great masters of Venice, Titian, Paul Veronese, and Tintoretto, had a far greater influence upon Reynolds's future practice than the great works in Rome. The rich effect of Venetian tone and colour were much more suited to his genius or taste, which decidedly inclined to the florid or ornamental; and however much his better judgment may have induced him to extol the grandeur of the Roman school in his discourses, it was the magnificence of the Venetian that captivated him, that guided his practice, that excited his emulation. From Venice he went through Turin to Paris, where he made a short stay, and returned to Plymouth towards the end of the year 1752, after an absence from England of three years and a half. At Plymouth he painted two portraits, one of which was of the Rev. Zachary Mudge, vicar of St. Andrews, and the old friend of his father.

By the advice of his early patron, Lord Mount Edgecombe, Reynolds returned to London, and again took apartments for a short time in St. Martin's Lane, where he painted his celebrated portrait of Joseph Marchi, in a Turkish dress, a young Italian whom he had brought with him as an assistant from Rome. This picture, which was painted in a florid style somewhat after the manner of Rembrandt, attracted much attention, and among other visitors his old master Hudson went to see it, who, having examined it somewhat closely, is reported to have said, with an oath, 'Reynolds, you don't paint so well as you did when you left England.' This has been invariably imputed to Hudson as an expression of envy, yet it would be very difficult to reconcile an approbation of that head with his own practice, which was in a style diametrically opposed to it. Reynolds himself in after life, upon seeing some portraits that he had painted thirty years previously, is said to have regretted that he had made so little progress. His execution in early life was very different from that of his latter years; his earlier manner was considerably more modest and less bold than his later, and proportionably more true to nature in consequence.

Reynolds's practice as a portrait-painter being now very considerable, he took a house in Great Newport Street, where he continued some years. One of his first works of value was a portrait of the then Duke of Devonshire, but that which established his fame as the first portrait-painter of his country was a full-length of his friend Commodore Keppel standing upon the sea-shore. It was about this time that he contracted an intimacy with Dr. Johnson, which only ended with the death of the latter. When Reynolds painted in St. Martin's Lane, his prices were for a head 10 guineas, a half-length 20 guineas, and for a whole length 40 guineas; in Newport Street they were at first respectively 12, 24, and 48 guineas, but his practice increased so rapidly that in 1758 he raised his price to 20 guineas for a head, and in 1760 to 25 guineas, the other sizes being in proportion.

At this period he was in the habit of receiving six sitters a day, and he valued his time at five guineas an hour. In 1761 he purchased a house in Leicester Square, where he fitted up an elegant painting-room, and built a spacious gallery for his rapidly-increasing collection of works of art; and here he resided the remainder of his life. His practice had now become so great, that he employed several assistants, of whom Marchi, the Italian, and Peter Toms, the celebrated painter of draperies, were the principal. This year the first public exhibition of works of art took place, in the room of the Society of Arts, in which Reynolds had four pictures; and in the exhibition of the following year, in Spring Gardens, he exhibited his portrait of Lord Ligonier on horseback (now in the National Gallery), and one of Sterne. These pictures, though not to be compared with his later performances, from a peculiarity of style and a richness of effect which distinguished them from the works of other artists, attracted universal attention, and established Reynolds as the favourite of the public. In 1762 he painted his celebrated picture of Garrick between Tragedy and Comedy; it was bought by the earl of Halifax for three hundred guineas, and has been engraved by Fisher. Dr. Johnson, in a letter written this year to Baretti, says, 'Mr. Reynolds gets six thousand a year.' In 1764 Reynolds and Johnson instituted the Literary Club, which was then limited to twelve members: Goldsmith and Burke were of the number.

Upon the foundation of the Royal Academy, in 1768, Reynolds was unanimously chosen president, and the honour of knighthood was conferred on him upon the occasion. The Academy was opened on the 1st of January, 1769, and the president delivered an appropriate discourse in commemoration of the event. Lecturing was no part of the duty of the president; it was a task which Sir Joshua imposed upon himself. He delivered altogether fifteen of these discourses, which have been translated into several languages, and have been generally and deservedly well received: they are too well known to require any particular comment here. They are certainly in many respects admirable; yet, with much sound and original criticism, they contain much also that is questionable.

In 1770 Sir Joshua raised his price for a head to thirty-five guineas. In 1773 he painted his celebrated picture of Count Ugolino with his Sons, from Dante: it was purchased by the duke of Dorset for four hundred guineas, and has been engraved by Dixon. This same year he proposed his plan of decorating St. Paul's Cathedral with a series of historical pictures, which was readily acceded to by Dr. Newton, bishop of Bristol and dean of St. Paul's; but Dr. Terrick, bishop of London, put a stop to the whole scheme, upon the plea that it was an introduction of popery: the other artists who had agreed to contribute works were West, Barry, Dance, Cipriani, and Angelica Kauffmann. This year is also memorable for two honorary distinctions which were conferred upon Sir Joshua; he was created Doctor of Civil Law by the university of Oxford; and was elected mayor of his native town, Plympton, a circumstance which gave him great gratification, and he presented the corporation with his portrait upon the occasion. About this time also he was elected member of the Imperial Academy of Florence, to which body he also sent his portrait. In 1779 he ornamented the ceiling of the library of the Royal Academy, in its apartments in Somerset House, with an allegorical painting representing Theory seated on a cloud, with the inscription 'Theory is the knowledge of what is truly Nature,' written upon a scroll in her hand. In this year he raised his price to fifty guineas for a head, which continued to be his charge during the remainder of his life.

In 1780 and the following years, Sir Joshua was engaged upon his great designs for the celebrated window of New College Chapel, Oxford, consisting of seven compartments for the lower range, containing the allegorical figures of the four cardinal and the three Christian virtues, Temperance, Fortitude, Justice, Prudence, Faith, Hope, and Charity; and above them the Nativity, lighted after the manner of the famous 'Notte' of Correggio. These designs were executed on the glass by Jervis of Dublin. The original design for the Nativity was purchased by the duke of Rutland for twelve hundred guineas, and was destroyed by the fire at Belvoir Castle in 1816: there is an engraving of it by Earlom.

In 1784 Sir Joshua painted his magnificent allegorical portrait of Mrs. Siddons as the Tragic Muse, a picture of its class perhaps unrivalled. According to Northcote, Sir Joshua valued this portrait at a thousand guineas; but it was purchased by W. Smith, Esq., for seven hundred: it has been engraved by Hayward. Upon the death of Allan Ramsay, this year, Sir Joshua was appointed principal painter in ordinary to the king. This year also he lost his old friend Dr. Johnson, who appointed him one of his executors, and bequeathed him his great French dictionary of Moreri and his own corrected folio copy of his English dictionary.

In 1786 he painted his Infant Hercules strangling the Serpents in the Cradle, for the Empress Catherine of Russia: it was sent to St. Petersburg, with two sets of Sir Joshua's discourses, one in French, the other in English, in 1789; and the following year, the Russian ambassador, Count Woronzow, presented him with a gold box, having the portrait of the empress upon the lid, set with large diamonds. His executors afterwards received fifteen hundred guineas as the price of the picture. This picture, which was remarkable for its rich effect of colour and forcible chiaroscuro, was the principal of Sir Joshua's historical pieces, and met with universal applause from the critics of the day. Even the eccentric Barry approved of it: he said 'the prophetical agitation of Tiresias, and Juno enveloped with clouds, hanging over the scene like a black pestilence, can never be too much admired, and are indeed truly sublime.' The effect of the tone and colour cannot be better expressed than by a painter of the day, who said that 'it looked as if it had been boiled in brandy.' The leading features of the composition were apparently taken from the 'Iconic' of the younger Philostratus on the subject: it has been engraved in mezzotinto by Hodges.

Sir Joshua painted three pictures for Alderman Boydell's Shakspere, the Cauldron Scene in Macbeth, Puck in Midsummer Night's Dream, and the Death of Cardinal Beaufort. For the first of these pieces the alderman paid Sir Joshua one thousand guineas, for the second one hundred, and for the third five hundred guineas.

Towards the end of 1791, a tumour, accompanied with inflammation, formed over his left eye; and being apprehensive lest the right should also be affected, he felt it necessary to desist from any further practice in his profession. He accordingly sent a letter to the council of the Academy, intimating his intention of resigning the office of president, on account of bodily infirmities; but he was induced to retain it upon the appointment of West as a deputy. He never again however resumed the chair; but died a few months afterwards, after a painful illness, of a disease of the liver, Feb. 23rd, 1792, in the sixty-ninth year of his age; and on his body being opened by Hunter, his liver was found to be more than double its natural size.

The body of Sir Joshua Reynolds, after lying in state in Somerset House, was buried with great pomp in St. Paul's Cathedral, where, some years after, a statue, executed by Flaxman, was erected to his memory.

The principal portion of his property, which amounted upon the whole to 80,000*l.*, he bequeathed to his niece, Miss Palmer, who shortly afterwards was married to the earl of Inchiquin, subsequently created marquis of Thomond. His collection of works of art sold for about 17,000*l.*, including several of his own works, and many unfinished and unclaimed portraits.

When we consider Sir Joshua's expensive habits and his liberal disposition, this large property enables us to form some idea of the immense patronage that he enjoyed. Upon the whole, his career from the beginning to the end exhibits an example of uninterrupted and brilliant prosperity that has perhaps never been surpassed. There are engravings from upwards of seven hundred of his works, mostly in mezzotinto. Northcote has given a list of about three hundred of his principal performances.

The day after Sir Joshua's death his eulogium from the pen of Burke, who was one of his executors, appeared in the papers. The following are extracts from this eloquent panegyric:—

'Sir Joshua Reynolds was on very many accounts one of the most memorable men of his time. He was the first Englishman who added the praise of the elegant arts to the other glories of his country. In taste, in grace, in facility, in happy invention, and in the richness and harmony of colouring he was equal to the greatest masters of the renowned ages.' 'He possessed the theory as perfectly as the practice of his art. To be such a painter he was a profound and penetrating philosopher.' 'His talents of every kind, powerful from nature, and not meanly cultivated by letters, his social virtues in all the relations and all the habitudes of life, rendered him the centre of a very great and unparalleled variety of agreeable societies, which will be dissipated by his death. He had too much merit not to excite some jealousy, too much innocence to provoke any enmity. The loss of no man of his time can be felt with more sincere, general, and unmixed sorrow.'

'As to his person,' says Northcote, 'in his stature Sir Joshua Reynolds was rather under the middle size, of a florid complexion, roundish blunt features, and a lively aspect; not corpulent, though somewhat inclined to it, but extremely active; with manners uncommonly polished and agreeable. In conversation his manner was perfectly natural, simple, and unassuming.' He was never married.

Sir Joshua Reynolds's literary productions, besides his discourses, were three contributions to the 'Idler,' some notes to Mason's translation of Du Fresnoy's 'Art of Painting;' a few notes for Dr. Johnson's edition of Shakspere; and his remarks upon the works of the Dutch and Flemish painters during his tour through Flanders and Holland in 1781. These last are full of admirable criticism, and display a rare discrimination of merits and demerits according to the intents and means of the various painters. It was during this tour that he first learnt to appreciate the wonderful powers of Rubens; he says of him, 'he was perhaps the greatest master in the mechanical part of the art, the best workman with his tools that ever exercised a pencil.' Several complete editions of his works have been published.

The partiality of British criticism has, with few exceptions, awarded Sir Joshua unqualified praise; he has been said to combine the beauties of Titian, of Rembrandt, and of Vandyck. 'To the grandeur, the truth, and simplicity of Titian,' says Northcote, 'and to the daring strength of Rembrandt, he has united the chasteness and delicacy of Vandyck.' That he combined many of the excellences of the two former cannot be questioned, yet in style and execution he was more artificial than Titian, and in effect less powerful than Rembrandt; and he was certainly as conspicuous for their defects as for their beauties. It remains however yet to be shown that there are in the works of Sir Joshua any traces of the purity and severity of Vandyck, not to mention the powerful drawing and exquisite modelling, by which Vandyck has so well proved that individuality is eminently consistent with breadth and grandeur.

Reynolds has been justly said to be the founder of the British school of painting. Through a happy combination and a judicious and powerful application of qualities, whether originating in natural feeling or acquired by selection from other masters, he struck out a new path in portrait, and by uniting graceful composition and breadth of light and shade with a rich and mellow tone of colouring, he invented a style of his own. This was a style, through its novelty and richness of effect, well calculated to captivate the taste of a public occustomed to the dry and feeble manner of the painters immediately preceding him, whether a Hudson, a Jervas, or a Kneller. But these attractive qualities, being the chief aim of the painter, naturally involved the sacrifice of the more solid properties of art through which alone true expression and individual character can be thoroughly attained, which we find more or less so well illustrated in the heads of Holbein, Raphael, and Vandyck, and which must always be imperfectly given when the features, though admirably placed, are merely indicated, however rich the colour, and however great the effect. The beauties of Sir Joshua's style were displayed to most advantage in the portraits of females and children, particularly the latter; and perhaps they are displayed in their utmost in the large fancy-piece of three ladies decorating a terminal figure of Hymen, in the National Gallery.

A great continental painter and critic (Mengs), whose own style however bordered upon an insipid imitation of the antique, has asserted that the principles and style of the English Reynolds were superficial and alluring. Although there may be less truth in this assertion than the foreign painter might have wished to imply, yet there is infinitely more in it than the partiality, or perhaps rather the biassed judgment of the English critic has hitherto enabled him to perceive. Reynolds's principal object was *effect*, yet with it he endeavoured to unite individual character; indeed his principle was that the likeness and individual character depended more upon the 'general effect' than upon the 'exact expression of the peculiarities or minute discrimination of the parts.' To this dangerous principle may be traced the characteristic defects of his style, of which the Holy Family, in the National Gallery, is a remarkable specimen. His great fear of falling into 'the vulgar error of imitating nature too closely,' and, while aiming at individuality, attaining only 'likeness,' led him into the opposite extreme of acquiring breadth at the expense of nature, by an almost total neglect of modelling. The endeavour to combine breadth with individuality in any great degree, with the means which Reynolds brought to the task, must have inevitably failed in every instance where the individual was not of a striking or marked character, as was the case in 'Lord Heathfield,' an admirable subject for Sir Joshua's pencil. These deficiencies might be concealed, but not supplied by any merits however great. When art differs from nature it is no longer an imitation of nature, but simply art; and notwithstanding the great vivacity of Sir Joshua's portraits, they are preeminently *works of art*; for instance, upon entering an apartment or a gallery which may contain specimens of his pencil, the hand of the artist is the first thing that strikes our attention, which is equally the case with engravings after his works; this is perhaps the only really infallible test of manner. The style of Raphael, who was the least mannered of all painters, because the most true to nature (Perugino's manner must not be confounded with Raphael's style), affords in this respect a striking contrast to Sir Joshua's; even the few specimens of his great works, in the collection of Marc Antonio's prints in the British Museum, show this satisfactorily.

Perhaps the greatest solecism in the current criticism upon Reynolds's style, and one of his reputed services to art, is that he 'exalted portrait to the dignity of history.' Now, whatever dignity an historical piece may possess must be obtained from the human character, whether it exist collectively or merely individually, and it can only be acquired through the principle of portraiture, of which character, and therefore its quality or inherent dignity, constitutes the essential principle. This has been well and often illustrated by Velasquez, Vandyck, and the great Italian masters in portrait, and in a much more eminent degree than it was ever done by Reynolds; perhaps in this respect Sir Joshua's most successful portrait is that of Lord Rodney. It is a quality generally less evident in portrait than in history, since it requires far greater skill to arrange effectively a single figure where the means are so limited, than to obtain a comparatively grand effect when some story is to be told through a variety of actors. In such case however the dignity of the whole can only arise from the individual dignity of the distinct or most important actors; for although it is an essential quality of grand composition, dignity forms no part of grouping. This may be illustrated by two great examples:—Paul, in the Cartoon of Paul preaching at Athens; and Andrea Doria, in the portrait by Sebastian del Piombo. The former would lose no portion of its proper dignity if separated from the surrounding groups; nor would the grand figure of Andrea Doria acquire any additional dignity, if the figures, which the imagination may suggest as appropriate actors in the scene, were supplied.

So great has been the influence of Reynolds's works, and so deeply has his style affected opinion upon art in England, that it has become the recognised standard of excellence in portrait. During the prevalence of such a conventional system of art or imitation, the true fountain of all criticism, an impartial comparison with nature in all her variety, cannot exist. The ambition of the young aspirant is to imitate the style or to catch the peculiarities of the universal favourite; he studies the works of artists rather than those of nature, and thus neglects the very means by which his models attained to fame and excellence. In England, Reynolds supplanted nature, and he became the painter's model. Hence arose that style of art denominated the English school, which is conspicuous for many of the defects of its founder and for few of his beauties; and necessarily so, for where unqualified admiration confounds beauties with defects, the only result of indiscriminate imitation must be the propagation of the defects alone, which, being the more evident and palpable, are so much the more easy of imitation. Thus Reynolds's *manner* became the English *style*. This circumstance is the greatest tribute that could be paid to his really great powers, for few artists have formed a school, fewer still have led a nation. All things however that are not founded upon the solid basis of truth, but only on imperfect or partial views of nature, can have no permanent effect, and the influence of Reynolds over British taste is now rapidly declining. The noble designs of Flaxman, by directing taste into another channel, and pointing out other objects of excellence, are calculated greatly to improve the character of poetic and historic art; though the effects of these truly classic compositions will be more conspicuous in the works of the rising generation of artists.

The deficiencies of Sir Joshua's style are more striking in his historical pieces than in his portraits. Its great characteristic, *effect*, and effect founded upon colour, is incompatible with the qualities peculiarly characteristic of the grand style—simplicity, severity, and dignity of expression, which can only result from the union of a grand style of design with a subdued colour. It has been often remarked that Sir Joshua's enthusiastic admiration, expressed in his discourses, of the works of Michael Angelo and the Roman school, strangely contrasts with his own style and practice, for the various styles of art certainly do not exhibit a greater contrast than that which exists between the florid *unfinish* and feeble line of Reynolds, and the sombre colour and the vigorous design of the Roman school. Reynolds's apology for this inconsistency of principle and practice was, that he suited his style to the taste of his times; yet it is an incontestable fact that he himself formed this taste. And although it is doubtful whether he preferred present prosperity to future fame, the style which he adopted has determined the ultimate fate of his works. To use his own words, 'Present time and future may be considered as rivals, and he who solicits the one must expect to be discountenanced by the other.'

A detailed account of events and incidents of Reynolds's life is given in the elaborate work, in two volumes, by Northcote.

REYNOLDS. [Theology.]

REZAT, THE CIRCLE OF THE (*der Rezatkreis*), in the kingdom of Bavaria, is situated between 48° 41′ and 49° 45′ N. lat. and between 10° 5′ and 11° 40′ E. long. It is bounded on the north-west by the circle of the Lower Main, on the north-east by that of the Upper Main, on the east by that of the Regen, on the south by that of the Upper Danube, and on the west by the kingdom of Würtemberg. The area is about 2000 square miles. The circle is traversed by several chains of hills, to which recent geographers have given the name of the Franconian Jura. With the exception of some few points, they are of no considerable elevation. These hills are capable of cultivation, and their sides are covered with forests. No other circle in Bavaria contains so many fertile valleys and such a rich soil. Of the great German rivers only the Danube just touches the circle for a short distance on the south, and receives, of the other rivers, only the Wernitz and the Altmühl. The principal river is the Regnitz, which is formed by the junction of the Rednitz and the Pegnitz, the latter again being formed by the junction of the Upper and the Lower Rezat. All the other rivers fall into the Regnitz, which itself falls into the Main near Bamberg, in the circle of the Upper Main.

No circle in the kingdom is better cultivated or more productive than the Rezat. All kinds of corn are cultivated, as well as millet, pulse, garden fruits, flax, hemp, tobacco, madder, and hops, and in such abundance that all, except madder, produce a surplus for exportation. The forests are very considerable. Most of them consist of firs, but there are some woods of oak, elm, &c.

The breed of cattle is a chief source of the wealth of the inhabitants, and is perhaps the best in the kingdom. The oxen (which are employed in agriculture, as well as horses) are large, strong, and very numerous; the breed of horses has been much improved by foreign importation; the breed of sheep continues to be improved by the importation of Merinos. But few swine and bees are bred, the people in these parts having a dislike to both. Large game, as deer and wild boars, is scarce; but small game, hares, partridges, &c., abounds. Domestic poultry is not so much bred as it might be. Fish abound both in the rivers and meres. There are no lakes. The circle is not rich in minerals. It produces very little iron, but has some useful kinds of stone, marble, clay, &c. It produces no salt, since Gerabronn has been ceded to Wirtemberg.

Of all the circles of Bavaria this has indeed the greatest number of manufactories, and contains several great manufacturing towns [FURTH, NURNBERG, SCHWABACH], and some of smaller importance (Erlangen [ERLANGEN], Roth, Dinkelsbühl), yet the products of the circle are almost entirely agricultural; the manufactures of woollen, cotton, linen, leather, stockings, &c. in the small towns, and by the country people, being quite unimportant.

The Rezat is the most densely peopled circle in Bavaria. The inhabitants, now 550,000, with the exception of the Jews and a few foreigners, are of German descent, and speak the High German-Franconian dialect. At least four-fifths of the inhabitants are Lutherans; the Calvinists are few. Of other religious persuasions, the Roman Catholics are the most numerous. The Jews are also numerous.

We take this opportunity to observe, that the king of Bavaria has changed the names of all the circles, or rather restored the antient historical names, as follows:—

	Late Names.	Present Names.
1.	Circle of the Isar.	Upper Bavaria.
2.	„ „ Lower Danube.	Lower Bavaria.
3.	„ „ Rhine.	The Palatinate.
4.	„ „ Regen.	Upper Palatinate and Ratisbon.
5.	„ „ Upper Main.	Upper Franconia.
6.	„ „ Rezat.	Middle Franconia.
7.	„ „ Lower Main.	Lower Franconia and Aschaffenburg.
8.	„ „ Upper Danube.	Swabia and Neuburg.

A few, but inconsiderable, changes have been made, by taking some districts from one circle and giving them to another.

RHÆTIA appears properly to have comprehended the whole country between the north of Italy and the Danube, and consequently to have included Vindelicia. Dion Cassius (liv., 22), in his account of the conquest of the Rhæti and Vindelici by Drusus and Tiberius, only mentions the Rhæti. Strabo often speaks of them (iv., p. 193, 206; vii., p. 449) as if they were only one people; and Tacitus in several passages appears to include Vindelicia in the province of Rhætia. In the time of Augustus however these two countries formed two separate provinces (Vell. Pater., ii., 39; Aurel. Vict., *Epit.*, c. i.; comp. Suet., *Aug.*, 21), of which Rhætia was bounded on the west by the Helvetii, on the east by Noricum, on the south by Gallia Cisalpina, and on the north by Vindelicia, from which it was separated by the Brigantinus Lacus (Boden See, or the Lake of Constance) and the river Œnus (Inn). It included the greater part of the Tyrol and the eastern cantons of Switzerland. The province of Vindelicia is treated of in a separate article.

The Rhæti are said to have been a Tuscan people, who were expelled from Italy by the Gauls, and who settled in the country afterwards called Rhætia, under a leader named Rhætus. (Plin., iii. 24; Justin, xx. 5; Liv., v. 33.) They are first mentioned by Polybius (xxxv. 10, § 18) as one of the people through whose country there was a passage across the Alps. They were a brave and enterprising race, and for a long time committed constant robberies in Gaul and the north of Italy. Augustus at length sent Drusus against them (B.C. 15), who subdued the southern part of the country, and delivered Italy from their depredations; but as they still continued to trouble the province of Gaul, Tiberius also was sent against them, who attacked them near the Boden See, and reduced the whole country. The greater part of their youth was carried away, and only sufficient left to cultivate the land. (Dion Cassius, liv. 22; Strabo, iv. 206.) The victories of Drusus and Tiberius are celebrated by Horace (*Carm.*, iv. 4, 14).

The great chain of the Alps passes almost through the centre of this province, and was called the Alpes Rhæticæ (Tac., *Germ.*, c. 1; *Hist.*, i. 70), which were inhabited almost to the top by different tribes of the Rhæti (Strabo, vii. 392). Several large rivers rise in these mountains, of which the most important are the Rhenus (Rhine), the Athesis (Adige), the Addua (Adda), and the Œnus. The valleys between these mountains were very fertile, and were particularly celebrated for their grapes, from which excellent wine was made. (Strabo, iv., p. 206.) The Rhætian wine was the favourite wine of Augustus. (Suet., *Octav.*, 77.)

The Rhæti were divided, according to Pliny (iii. 24), into many states or tribes. Of these the most important were: the Lepontii, in the south-western part of the province (Cæs., *Bell. Gall.*, iv. 10; Strabo, iv., p. 204); the Tridentini, in the south-eastern; the Genauni, whom Horace (*Carm.*, iv. 14) mentions, east of the Lepontii; the Vennones, near the sources of the Attagis (Etsch), which flows into the Athesis; the Brixentes, north of the Tridentini; the Brenni, or Breuni, north of the Rhætian Alps; and the Brigantii, in the north-western part of the province, on the borders of the lake Brigantinus. The only town of any importance in Rhætia was Tridentum (*Trent*) on the Athesis, the capital of the Tridentini.

RHAGÆ. [PERSIA.]

RHAMNA'CEÆ, a natural order of Exogens, remarkable for having a valvate calyx, hooded petals, opposite to which their stamens are inserted into the tube of the calyx, and a superior or half-inferior fruit which is either dry or fleshy. The species are all shrubs, with small greenish or inconspicuous flowers. Those most common in this country are the Rhamnus frangula (Black Alder), Rhamnus catharticus (Buckthorn), Paliurus australis (Christ's Thorn), and the evergreen Alaternus, a kind of Rhamnus. The useful species are of some importance: Rhamnus catharticus and several others have purgative berries; Rhamnus infectorius yields the French berries of the shops employed for dyeing yellow; the fruit of the Jujube, Zizyphus jujuba and vulgaris, is subacid and eatable, and the species are cultivated for it in the south of Europe and the temperate parts of Asia; Zizyphus Lotus gave its name to the Lotophagi, or Lote-eaters, of Africa; and Rhamnus frangula is extensively cultivated for the manufacture of charcoal. [PALIURUS; RHAMNUS; ZIZYPHUS.]

Rhamnus Alaternus.

1, a flower about to expand; 2, a flower cut open to show the position of the stamens and petals; 3, a transverse section of a fruit, and seeds.

RHAMNUS, or Buckthorn (the word is Greek, Ῥάμνος), a widely diffused genus of the natural family of Rhamnaceæ, chiefly found in the temperate parts of Europe, in Siberia, and in the Himalayas at elevations of 6500 feet, also in the New World, and at the Cape of Good Hope.

The genus is characterised by having an urceolate 4-5-cleft calyx. Petals wanting, or emarginate. Anthers ovate, 2-celled. Disk thin, overspreading the tube of the calyx. Ovary superior, 3- or 4-celled. Styles 3 or 4, distinct or united. Fruit fleshy, with 3 or 4, or, in consequence of abortion, 2 fibrous indehiscent stones.

The berries of one species, the Rhamnus catharticus, have long been known for their purgative properties, and still continue to hold a place in several Pharmacopœias. This property is participated in by those of other species, as well as by their inner bark. The berries of several species of Rhamnus form articles of commerce from the Mediterranean, under the name of French, Turkey, and Persian berries, grains d'Avignon, &c., being valued on account of the colouring-matter which they yield, and which varies from yellow to green. This M. Brongniart supposes to be owing rather to different degrees of ripeness than to essential differences in nature. Sap-green is a mixture of the juice of these berries with those of some others. R. infectorius, saxatilis, amygdalinus, catharticus, and Clusii are the species generally employed; some for dyeing morocco leather of a yellow colour, others for dyeing wool, and the bark of some for striking a black with the salts of iron. The Lycium of the antients is supposed by some to have been a species of Rhamnus [LYCIUM]; hence also one species has been called R. Lycioides: it has a hard yellow wood. Another, R. theezans, is said to be employed as a substitute for tea even in China.

RHAMNUS CATHA'RTICUS (called also Spina cervina, hence Buckthorn), an indigenous shrub, flowering in May, and ripening its berries in September, at which time they are collected. The berries are about the size of a peppercorn, black externally, but within of a deep violet, the pulp enclosing three or four seeds. The taste is nauseous and repulsive at last, though at first sweetish and only bitter. They contain a peculiar extractive, a colouring principle, acetic acid, and gum. The fresh and dried berries, the expressed juice, or a syrup prepared from them, all possess purgative properties, exemplified in that form which has led to the designation *hydragogue*. Its action is attended with much sickness, griping, and thirst. All the forms of exhibition are objectionable, but particularly the berries, either fresh or dried: yet this acrid and almost poisonous article is retained in practice, and is a common domestic medicine, especially for young children, the most unsuitable of all for its employment. It should be restricted to the arts, in which it is serviceable, being the source of the pigment called sap-green or bladder-green.

The berries of several different shrubs are said to be substituted for those of the R. catharticus; a circumstance which is fortunate, if any more harmless are made to replace them. Buckthorn berries are themselves used to adulterate cubebs.

RHATANY. [RATANY; KRAMERIA.]

RHAZES, or RAZES, the common Latinized name of one of the most famous of the antient Arabic physicians, who is also sometimes called Rasæus, Rases, Rasis, Razeus, Razeus, Razi, Rhases, Rhazeus, Rhazis, or Arrasi. His names (as given by the anonymous author of the 'Arabic. Philosoph. Biblioth.,' quoted by Casiri, 'Biblioth. Arabico-Hisp. Escur.,' tom. i., p. 264) were Mohammed Ben-Zakaria Abu-Bekr Al-Razi. He was born and brought up at Rai, the most northern town (according to D'Herbelot, *Biblioth. Orient.*) of Irak Ajemi, and showed from his youth a great inclination for the sciences. He acquired great philological and philosophical knowledge, but chiefly devoted himself to music; and even in his thirtieth year, he was only known for his skill in singing and playing on the guitar. He afterwards, when past the age of forty (Abulfeda, *Annal. Musl.*, tom ii., p. 347) applied himself exclusively to the study of medicine and philosophy, and repaired to Bagdad, where Ibn Zein Al-Taberi was his instructor, from whom he acquired much important information. Upon his return to Rai, he became director of the hospital in that town, and afterwards of that at Bagdad. He was held in great estimation by the contemporary princes, and was called the Galen of his time. He travelled much, and visited both Jerusalem and Africa: he is said also to have visited Spain (Leo Afric., *De Viris Illustr. Arab.*, cap. 6; apud Fabric., *Biblioth. Græc.*, tom. xiii.), where, in passing through the streets of Cordova, he saw a crowd collected round the body of a man who was said to have just fallen down dead. He caused him to be beaten all over with rods, and particularly on the soles of his feet, and thus in less than a quarter of an hour restored him to life. Upon being asked about the invention of this singular remedy, he said that he had seen it used with success in a similar case by an old Arab; and added, that 'experience is of more use than a physician.'* To Prince Al-Mansour, to whom he dedicated his work entitled *Ketáb Al-Mansouri*, 'Liber ad Al-Mansorem,' he wished also to present his 'Confirmatio Artis Chimiæ,' and left Bagdad for this purpose. The prince was much pleased, and gave him a thousand dinars;† but wished at the same time to see a trial of the discoveries described in the book, and granted a considerable sum for the preparation of the necessary apparatus. The experiments however did not succeed; which so enraged Al-Mansour, that he called him a liar, struck him a violent blow on the head, and ordered him to pack up his things quickly and go back to Bagdad. (Ibn Khallikán, *Vitæ Illustr. Viror.*) This blow is said to have afterwards occasioned his becoming blind, but Abulfaraj (*Hist. Dynast.*, p. 291) and Casiri (*loco cit.*) attribute this misfortune to eating beans. At first he wished to have an operation performed; but as the surgeon could not tell him how many membranes the eye contained, he refused to let him touch his eyes; and when some one represented to him that the operation might nevertheless succeed, he replied, 'I have seen so much of the world, that I am wearied of it.' He was so charitable and liberal, that he often gave money to his poor patients, and lived himself in poverty. He died at an advanced age, either at Bagdad or Rai, A.H. 311, or more probably 320 (A.D. 923 or 932), under the khalifat of Moctader Billah, the eighteenth of the race of the Abbassides. (Wüstenfeld, *Gesch. der Arab. Aerzte.*)

His works amounted to more than two hundred, and the bare titles, as given by the anonymous author quoted above, take up four folio columns in Casiri; of these only those that have been published can be noticed here; and for a more complete account of his medical opinions and practice, the reader may consult Freind's 'Hist. of Physic,' Sprengel's 'Hist. de la Méd.,' and Haller's 'Biblioth. Medic. Pract.' The principal work of his that we possess is called *Al-Háwi*, 'Continens.' An attentive perusal of this book is sufficient to prove that Rhazes could not have published it in its present form, as the diseases are mentioned without the least order; the treatment of many of them is not touched upon; the author is sometimes quoted in the third person (*Rhaz. Contin.*, lib. vi., cap. 1, pag. 125, col. 2; lib. viii., cap. 2, pag. 176, col. 4); and lastly, one meets with the names of several Greek physicians more modern than Rhazes. To all these arguments against the authenticity of the work may be added the important testimonies of Haly-Abbas and Abulfaraj. The former gives Rhazes all the praise he really deserves; but adds, that the 'Al-Háwi' is certainly not the most evident proof of his science and good taste, but that probably he only left the work to his descendants in the form of an unfinished sketch. (Haly-Abbas, *Prolog.*, pag. 6, ed. Lugd., 1523, 4to.) Abulfaraj says positively that the authentic 'Al-Háwi' was never published. (*Chron. Syr.*, p. 172. Ed. Bruns et Kirsch.) Notwithstanding these unanswerable proofs against the authenticity of the work, it cannot be doubted that great part of it was written by Rhazes; and it will always be considered one of the most valuable repositories of the medical science of the Arabians. (Sprengel, *Hist. de la Méd.*) The original Arabic has never appeared; but several Latin translations under the various titles Elhavi, Helchauy, Elchavi, Elkavi, Hawi, &c.) were published in the fifteenth and sixteenth centuries. The first edition is scarce, and was printed at Brescia (*Brixiæ*), 1486, fol., 2 vols., in black-letter, with two columns in a page, under the following title: 'Liber Elhavi, seu Totum Continentis Bubikir Zacharie Errasis Filii, traducti ex Arab. in Latin. per Mag. Ferragium, Medicum Salerni,' &c. The last edition is probably that by Hieron. Surianus, Venet., 1542, fol.

The most celebrated of his works is his treatise on the

* A somewhat similar story is told of Asclepiades (Pliny, *Hist. Nat.*, vii. 37; xxvi. 8; Celsus, *De Med.*, ii. 6; Apuleius, *Florid.*, lib. iv., p. 362) and of several other physicians, both in antient and modern times (*Cyclop. of Pract. Med.*, vol. iii., p. 316): among the rest, a very curious one is told by Ibn Abou Osaibiah, *Oyoun al-anba fi tabacat al-atebba*, 'Fontes Relationum de Classibus Medicorum,' cap. 12, of Salih Ben Bahlah, an Indian physician at the court of Harúun Al-Rashíd. [SALIH.]

† The dinar (derived from the Greek δηνάριον) was a gold coin, equal at first to twenty, and afterwards to twenty five dirhems (Casiri, *Biblioth. Arabico-Hisp. Escur.*, tom. ii., p. 173); and is commonly supposed to have been worth about a Venetian zecchin (D'Herbelot, *Biblioth. Orient.*), or to a German ducat (Freytag., *Lex. Arab.*). The sum given to Rhazes would therefore amount (if we reckon the dinar as 9s. 4½d.) to £468 15s.

small-pox and measles, which is the oldest account that we possess of these two diseases. 'He was not however the first writer on the subject, for he himself quotes from Aaron and other of his countrymen, who had formerly given imperfect histories of these diseases. The treatment of them, as described by him, is sufficiently accurate and judicious, that is to say, he directs in general to bleed at the commencement, then to give cooling and acidulated draughts, with gentle laxatives, &c.; and he properly recommends to pay particular attention to the throat and eyes.' (Mr. Adams, Append. to Barker's Lempriere, 1838.) Of this little work there is an edition in Arabic and Latin, by J. Channing, Lond., 1766, 8vo. It was printed from a manuscript at Leyden, and Dr. Russell says (Append. to *Nat. Hist. of Aleppo*) that he had the book collated with other MSS. in the East, and that the readings were upon the whole found very exact. It has been translated into several antient and modern languages. A Greek translation was published by Jac. Goupylus, at the end of his edition of Alexander Trallianus, Lutet. Par., 1548, fol., entitled 'Rhazæ de Pestilentia Libellus ex Syrorum Lingua in Græcam translatus.' It was translated into Latin by Georg. Valla, Basil., 1529, 8vo., with Michael Psellus, 'De Victus Ratione;' by Nic. Macchellus, Venet., 1555, 8vo.; by Salomo Negri, the Syrian, assisted by J. Gagnier and Th. Hunt, and published by Dr. Mead, in his work, 'De Variolis et Morbidis,' Lond., 1747, 8vo.; Channing's translation was republished by Haller, in the seventh volume of his 'Medicæ Artis Principes,' Lausanne, 1772. It was translated into French by Sebast. Colin, Poitiers, 1556, and by J. J. Paulet, in the second volume of his 'Hist. de la Petite Vérole,' 1763, Paris, 12mo., and there is an English translation in the English edition of Dr. Mead's medical works.

The ten books, dedicated to Al-Mansor, *Ketáb Almansóuri*, 'Liber ad Almansorem,' contain a complete system of medicine, drawn from Arabic and Greek sources. The first book is on anatomy and physiology; the second, 'De Significationibus Temperaturarum;' the third, 'De Alimentis et Simplicibus;' the fourth, 'De Sanitatis Tuendæ Ratione;' the fifth, 'De Morbis Cutis, et de Cosmeticis;' the sixth, 'De Victu Peregrinantium;' the seventh, 'De Chirurgia;' the eighth, 'De Venenis;' the ninth, 'De Curatione Omnium Partium;' and the tenth, 'De Febribus.' The writers from whom the work is chiefly compiled are Hippocrates, Galen, Oribasius, Paulus Ægineta, and Aëtius. It contains an excellent treatise on the qualities necessary for a physician (Tract. iv., cap. 32, pag. 78, ed. Lugd., 1511, 8vo.), in which he declares that a person of much learning and little experience is more to be trusted than one of much experience and little learning; for he adds, how is it to be supposed that the private stores of any one individual should be at all worthy to be compared with the accumulated treasures of antiquity? There is also a very curious chapter (Tract. vii., cap. 27, pag. 123) on quacks and impostors, which has been translated and inserted by Freind, in his 'History of Physic.' He is said by Jo. Bapt. Silvaticus (*Controv. Med.*, sec. 14) to be the first person who recommended intoxication once or twice a month (*Almans. Tract.*, iv., cap. 5, pag. 64), which precept was repeated by Avicenna (*Cantic.*, part ii., sec. 34, pag. 383, ed. Venet., 1564), and others, and vigorously opposed at Paris in the seventeenth century, in two theses, by Hommets and Langlois. The ninth book was for several centuries one of the most celebrated text-books for medical students, but, notwithstanding its fame, Sprengel and Haller both declare that it contains nothing original. The Al-Mansor to whom the work is dedicated has by some been supposed to be the caliph of Bagdad, who lived above two centuries before the time of Rhazes, by others a prince of Cordova, who lived long after. Rhazes himself solves the difficulty, and says (*Antidotar. Prolog.*, pag. 78, b. ed. Venet., 1500) that he was a prince of Khorassán (*domino Corascem*), and nephew of the caliph Moktasi, named Al Mansóur Ibn Ishac Ibn Israel Ibn Ahmed. The whole of the Arabic original of this work has never been published, but a small extract (lib. ix., cap. 7) is inserted, with a Latin translation, in Reiske's 'Opusc. Med. ex Moniment. Arab.,' p. 70, sq. The first Latin translation was published with several other of his smaller works, Mediol., 1481, fol., in black-letter; the last edition came out at Basel, 1544, fol. There are also several other works that have been published with the 'Liber ad Almansorem,' *e.g.* 'Liber Divisionum,' 'Aphorismi,' 'De Juncturis,' 'Antidotarium,' 'De Morbis Infantum,' 'Introductio in Medicinam,' 'De Calculo Renum et Vesicæ,' 'De Facultatibus Partium Animalium,' &c. None of these little works contain anything of much importance.

RHEA. (Ornithology.) [STRUTHIONIDÆ.]

RHE'GIUM (in Greek, *Rhegion*, Ῥήγιον), now Reggio, one of the oldest Greek towns in Italy, is situated on the Fretum Siculum, or strait which divides Italy from Sicily. Rhegium was a colony of the Chalcidians, who were joined by a party of Messenian emigrants who left their country during the first quarrel between Messene and Sparta, in consequence of the affair of Limnæ. (Strabo, p. 257.) Its name Rhegion is said to be derived from a Greek verb (ῥηγ-νυ-μι) which means to tear or rend asunder, from a tradition of a physical convulsion by which Sicily became detached from the continent of Italy. (Strab., p. 25-.) Both the town and the name probably existed previous to the establishment of the Chalcidian colony, as Diodorus and other antient writers place its foundation in the Heroic times.

After the taking of Ithome, and the end of the first Messenian war, a fresh colony of Messenians, led by Alcidamas, settled at Rhegium about 723 B.C.; and after the capture of Eira, a third party of Messenian emigrants, led by two sons of Aristomenes, joined their countrymen at Rhegium, which became a very populous and flourishing city, and extended its dominion over other towns and districts. Charondas of Catana is said to have compiled a code of laws for Rhegium. The government appears to have been a kind of open aristocracy, which, according to some accounts, was vested in one thousand of the citizens.

About 494 B.C., Anaxilaus, a citizen of Rhegium, of a Messenian family, usurped the supreme power. He took the town of Zancle on the opposite side of the strait, and colonised it with his Messenian countrymen, who gave it the name Messana. [MESSENIA.] The poet Simonides composed a poem on the occasion of Anaxilaus having gained the prize at the Olympic Games with his mules. Anaxilaus married a daughter of Therillus, tyrant of Himera, who, being afterwards defeated by Theron of Agrigentum, took refuge at Carthage. Anaxilaus and Therillus invited the Carthaginians to the first invasion of Sicily (480 B.C.), which was defeated by Gelon of Syracuse. Anaxilaus died shortly after, and his sons were subsequently driven away from both Messana and Rhegium. The towns then became independent of each other, but remained allied by the ties of common origin, and both joined the league of Naxos, Leontini, Catana, and other towns of Sicily, of Chalcidian origin, against Syracuse and the other Dorian cities. The contest led to the first Athenian expedition (427 B.C.), which came to the assistance of the allies. The harbour of Rhegium became the station of the Athenian fleet, and the Rhegini joined the Athenian forces. (Thucyd., iii., 88.) After several desultory combats, the Sicilian towns agreed to a peace among themselves, and the Athenian forces returned home. During the second Athenian expedition against Syracuse, which ended so fatally for the Athenians, Rhegium remained neutral. Afterwards a long struggle began between Rhegium and Dionysius the elder, tyrant of Syracuse, which terminated with the ruin of Rhegium. Dionysius, wishing to strengthen himself by alliance with the Greek cities of Italy for his impending contest against Carthage, sent to ask one of the maidens of Rhegium for a wife. The Rhegians, irritated against Dionysius for his treatment of Naxus and Catana, the citizens of which he had driven away, and sold many as slaves, replied that they could only give him the daughter of their public executioner. Dionysius then applied to the Locrians, who gave him in marriage Doris, daughter of one of their chief citizens, and from that time he vowed vengeance against Rhegium. After having defeated the Carthaginians, he sailed from Syracuse with 100 galleys and a large body of men, which he landed near Rhegium. They scaled the walls, and were near taking possession of the town, when a fire broke out, and compelled them to return. A new expedition from Carthage against Syracuse obliged Dionysius to leave Rhegium in peace for a time. Having again defeated the Carthaginians, Dionysius equipped a fleet of 120 galleys, with an army of 20,000 foot and 1000 horse, with which he landed near Locris, and then ravaged the territory of Rhegium. But the towns of Magna Græcia sent assistance to Rhegium; and a storm arising, in which many of the Syracusan ships were wrecked on the coast, Dionysius was obliged to retire to Syracuse (390 B.C.). The next year he came again to Italy, besieged, took, and destroyed Caulon, defeated an army of the Greek Italian cities, and obliged them to separate themselves from Rhegium, which he besieged again in the following year with a large force. The Rhegians made a brave resistance, but they were compelled to surrender through famine (387 B.C.). Many of the inhabitants were found dead; fifteen thousand of the remainder were sent to Syracuse as slaves; some of the wealthiest ransomed themselves. Python, their commander, was put to a cruel death with all his family by Dionysius, who razed the walls of Rhegium, and obliged the neighbouring towns of Magna Græcia to pay allegiance to him. Under his successor, Dionysius the Younger, Rhegium recovered its independence, and gradually some part of its former prosperity. After the expulsion of Dionysius the Younger from Syracuse, and the death of Timoleon, Rhegium was again besieged by the Syracusans, when Agathocles, himself an exile from Syracuse, came to its assistance with a party of his emigrant countrymen, and obliged the besiegers to raise the siege (317 B.C.). After the death of Agathocles, his numerous Campanian mercenaries, who were called Mamertines, being dismissed from the Syracusan service, took possession of Messana, and of all the property of the former inhabitants.

Not many years after, while Pyrrhus was waging war in South Italy and Sicily, Rhegium applied to Rome for assistance. The Romans sent a body of 4000 men, raised in the Latin colonies in Campania. These auxiliaries, finding themselves far from Rome, broke through all the restraints of discipline, and rising against the peaceful inhabitants whom they had been sent to protect, killed most of the men, took possession of their houses and property, and appropriated their wives and daughters to themselves. After the final retirement of Pyrrhus from Italy, the Roman senate sent the consul Genucius Clepsina with an army to punish the traitors. The Campanians defended themselves obstinately, and when at last they surrendered at discretion, they were reduced to a few hundreds, who were all put to death about 270 B.C. This happened shortly before the beginning of the first Punic war. The surviving citizens of Rhegium were restored to their houses and property, and to their municipal independence under the protection of Rome. Rhegium recovered its prosperity, and was a place of importance to Rome on account of its neighbourhood to Sicily. The Aquilian road terminated at Rhegium. The town was almost destroyed by an earthquake just before the breaking out of the Marsian war. In the time of Strabo, Rhegium, Tarentum, and Neapolis were the only towns of the numerous Greek colonies in Italy that retained the Greek language, manners, and customs. (Strabo, p. 253.)

After the fall of the Western empire, Rhegium remained subject to the Eastern emperors, and its archbishop was metropolitan of the whole country of the Bruttii. The Saracens from Sicily took possession of Rhegium, and planted a number of date-trees in the neighbourhood, a few of which have perpetuated themselves to our times. (Swinburne, *Travels in the Two Sicilies.*)

Rhegium was taken by the Normans in the eleventh century, since which time it has always been a part of the kingdom of the Two Sicilies.

In the sixteenth century Reggio was sacked three times by the Turks, in 1543 by Barbarossa, again in 1558, and lastly in 1593. The great earthquake of Calabria, in 1783, completely ruined the town of Reggio; not a single building remained entire. Reggio has been since rebuilt on a regular plan; it spreads along the declivity of a hill down to the sea. A wide street, called La Marina, runs along the sea-shore, and another street, parallel to it, runs through the centre of the town, and is intersected at right angles by various streets. The view of the opposite coast of Messina and its verdant hills, backed by the huge mass of Ætna, is truly magnificent. The Apennines near Reggio are rugged and bare, but the plain around Reggio is extremely fertile, and the ground is very valuable, most of it being laid out in orange and lemon plantations. The extracting of an essence from the rind of the orange and lemon, and the rearing of silk worms, constitute important branches of industry. Reggio is a great nursery of orange and lemon plants for all parts of the kingdom. The climate is temperate, and the atmosphere remarkably pure. The population of Reggio amounts to nearly 20,000. The inhabitants are lively and sociable, and are mostly in easy circumstances; the women are good-looking, and it is altogether one of the pleasantest towns in the kingdom of Naples. [CALABRIA.]

The antient port no longer exists. The small craft of modern Reggio anchor a little to the north of the town, opposite the village of Pentimele. Reggio is about eight miles south-east of Messina.

Coin of Rhegium.

British Museum. Actual size. Silver.

RHEIMS. [REIMS.]

RHEINPROVINZ. The province of the Rhine is sometimes called Rheinpreussen, or Rhenish Prussia, though this latter name is more generally understood to include the province of Westphalia. It lies between 49° 10′ and 51° 55′ N. lat., and between 5° 55′ and 8° E. long. It is situated on both sides of the Rhine, and comprises the grand-duchy of the Lower Rhine, and the duchies of Juliers, Cleves, and Berg. It was formerly divided into two provinces, the Upper and Lower Rhine. It contains the five governments of Cologne, Düsseldorf, Coblenz, Treves, and Aachen (Aix-la-Chapelle). Except the circle of Wetzlar, which is encompassed by Nassau, Hesse-Darmstadt, and Hesse-Cassel, it is bounded on the north by Westphalia, on the east by Nassau and Hesse-Darmstadt, on the south by France, and by the territories belonging to Bavaria, Saxe-Coburg, and Hesse-Homburg, on the left bank of the Rhine, and on the west by the grand-duchy of Luxemburg, Belgium, and the Netherlands. The area is 10,230 square miles, and the population 2,473,723 inhabitants, or nearly 242 to a square mile.

The northern, eastern, and southern parts of the province are mountainous.

The Hundsrücken, which extends between the Moselle, the Rhine, and the Nahe, forms the west side of the valley of the Rhine and the east side of the valley of the Moselle, and is connected on the south with the Vosges. Its highest point, within the province, is in the Soonwald, which is 2015 feet above the level of the sea.

The Eifel, which is a wild and partly very sterile chain, is a continuation of the Ardennes, and extends between Luxemburg, the Moselle, and the Rhine. In the eastern part there are numerous extinct volcanoes.

The Westerwald is a rude chain, which likewise shows many traces of volcanic action. The most interesting part of it is that called the Siebengebirge near Bonn; some parts of this chain are from 1200 to 1400 feet above the level of the sea.

The principal rivers are the Rhine, the Moselle, and the Lippe, which are navigable; the many smaller streams, most of which fall into the Rhine, are either not navigable or only by very small vessels. There are only two inconsiderable lakes in the province. The climate is temperate; the air on the right bank of the Rhine is pure and healthy; on the left side damp fogs are more frequent, especially in the north-west part, where there are many marshes; on the mountains it is cold. The natural productions of this province are equally numerous and valuable. The higher parts of the mountains are crowned with noble forests, and the declivities are covered with vineyards. The mineral kingdom yields silver, iron, copper, lead, calamine, marble, slate, freestone, millstones, basalt, porphyry, alum, manganese, sulphur, coals, and salt. Where the country slopes to the Rhine there are productive corn-fields and rich pastures; between the mountains there are fertile valleys, where flax, hemp, hops, and tobacco are grown, and fruit and garden produce of every kind are cultivated in great abundance. Game is plentiful, and all the domestic animals are bred in sufficient number.

But the great source of the prosperity of the province is the Rhine, which, from its junction with the Nahe to the village of Hochheim on its right bank, forms the natural boundary between the duchy of Nassau and the government of Coblenz; it then traverses the governments of Cologne and Düsseldorf, and leaves the Prussian territory at Schenkenschanz, opposite the Dutch village of Lobith, having passed through this province as one undivided stream for 180 miles. On the banks are many vestiges of Roman works and ruins of castles of the middle ages. The small rivers and streams are applied to turn mills and to work manufacturing machinery of every kind; for this, says Hassell, is the most industrious (*i.e.* manufacturing) province not only of the Prussian monarchy but of all Germany.

'It is perhaps not unsuitable,' says Nemmich, 'to call the duchy of Berg an England in miniature; we find in it a Manchester, a Leeds, a Sheffield, a Spitalfields, a Birmingham.' This was written above twenty years ago, and the comparison is now even more appropriate. [JULICH-CLEVE-BERG.] The trade of the province is very extensive. The numerous manufactures are particularly described in the articles on the several towns. [AIX-LA-CHAPELLE; BARMEN; DUSSELDORF; ELBERFELD, &c.] With regard to religion, about 1,830,000 are Roman Catholics, 610,000 Lutherans and Calvinists, 2000 Mennonites, and 30,000 Jews. There are 2345 Roman Catholic and 880 Protestant elementary schools, 49 mixed schools, and 59 Jewish schools.

(Dieterici, *Statistische Uebersicht*, &c., 1838; Hassell; Stein; Hörschelmann; *Weimar Almanach*, 1840: Schlieben, *Gemälde der Preussischen Monarchie*; Mayer, *Beiträge zur Statistik der Königlich-Preussischen Rheinlande*.)

RHEIN-HESSEN (that is, Rhenish Hesse) is one of the five provinces of the grand-duchy of Hesse Darmstadt. It is bounded on the north by Nassau, on the north-east and east by the province of Starkenburg (separated however from both by the Rhine), on the south and south-west by Bavaria, and on the west by Rhenish Prussia. It forms one connected whole; only two communes, Kastel and Kortheim, being on the right bank of the Rhine opposite to Mainz. The surface is undulating, alternating with hills, valleys, and small plains. It is a hilly but not a mountainous country; the Rochus, or Hesselsburg, near Bingen, is but a great hill, being only 725 Paris feet above the Rhine. Nearly four-fifths of the country are arable land, one twenty-fifth pasture, almost one-fifteenth vineyards, and less than one twenty-eighth forests. The principal rivers are the Rhine, the Main, and the Nahe, besides which there are several smaller streams that rise in the Vosges or in Mont Tonnerre. The soil is light, and on the bank of the Rhine sandy, but it is everywhere extremely fertile, and the climate is so mild that the country is sometimes called the Wonnegau (that is, the delicious valley). The natural productions are oats, spelt, barley, rye, and millet (of all which, notwithstanding the great population of the country, considerable quantities are exported), flax, tobacco, and potatoes in great abundance. The cultivation of fruit is very general; all the roads are bordered with fruit-trees. Some of the wines are of excellent quality; the quantity produced in ordinary years is very considerable. The forests do not yield sufficient timber for home consumption. Oxen, swine, and poultry are numerous; but there are scarcely any sheep; most of the oxen are employed in agriculture. There are only a few manufactures, which are chiefly of linen, cotton, and leather. The province has a very active and profitable export trade in its own productions, and a good transit and commission trade. The following statement is from the Weimar Almanac for 1840: 'Area 520 square miles. Population (census of 1838) 206,900; the annual increase is estimated at 7500. Religion (in 1832): Evangelical, 87,695; Roman Catholics, 93,764; Moravians, 871; Jews, 7307. Principal towns: BINGEN; MAINZ; WORMS.'

RHEINGAU, THE, is a valley six leagues in length and two leagues in breadth, in the duchy of Nassau, between the Rhine and the Höhe, and extending from Biberach to below Rudesheim. It is formed by the Rheingaugebirge, begins at the village of Nieder-Walluf below Mainz, and ends at the village of Lorrich. It contains about 20,000 inhabitants, and the principal town is Ellfeld. This valley is protected on the north by the Taunus chain of mountains, and is celebrated for its beauty and fertility, and especially as producing the finest Rhenish wines. With regard to the cultivation of the vine, it is divided into the upper and the lower districts, that is, the villages on the heights and those on the banks of the rivers. The strongest wines are produced on the highest eminences; the m[...] wholesome in the middle region; the wines of the vall[...] are not so soon fit for use. The best wines are the Nier[...]stein, the Johannisberg, the Rudesheim, and the Biberac[...]. That of Hochheim (hock) is generally reckoned am[...] the wines of the Rheingau, though Hochheim is bey[...] the boundaries of the valley as above described. M[...] fruit is cultivated on the mountains. At a distance from t[...] banks of the Rhine there are considerable forests.

RHENA'NUS, BEA'TUS, was born in 1485, [...] Schlettstadt in Alsace. His father, though originally a b[...] cher of Rheinach (whence the name Rhenanus), was a m[...] of considerable property, and gave his son the best educa[...] that could be had in those times. After the boy h[...] finished his elementary education, his father sent him to Paris, where he studied philosophy and antient literat[...] From Paris he went to Strasburg and Basel, and in the [...]ter place he formed an intimate friendship with Erasmus a[...] Gelenius. During his residence at Paris he had been e[...]ployed in the office of the learned printer H. Stephens, a[...] he occupied himself in a similar manner in the pri[...] establishment of Froben at Basel.

In 1520 his father died, and left him all his property; [...] although Rhenanus retired to Schlettstadt, he continued [...] favourite study of the antients with the same zeal; and [...] order not to be disturbed, he requested and obtained fr[...] the emperor Charles V. an exemption from all pu[...] offices. He had always objected to marrying, but at l[...] his friends prevailed upon him, and at the advanced age [...] 61 he married. A few months afterwards he was attack[...] by a disease, from which he sought relief in the baths of Baden, but as they only increased his sufferings, he returned home, and on his way thither he died, at Strasburg, on th[...] 20th of May, 1547. His body was carried to his native pla[...] and buried there.

Rhenanus is chiefly celebrated as the editor of many [...]tient authors, on whom he bestowed great care, with t[...] view of giving a correct text. The following is a chron[...]gical list of most of his editions:—

'Quintus Curtius,' Basel, 1517; 'Maximus Tyrius,' Ba[...] 1519; 'Velleius Paterculus,' Basel, 1520 (this is the ed[...] princeps of that historian); 'Tertulliani Opera,' Basel, 15[...] 'Auctores Historiæ Ecclesiasticæ,' containing Eusebi[...] Pamphilus, Nicephorus, Theodoret, &c., 1523-25 (reprint[...] at Paris in 1541); 'Plinius, Historia Naturalis,' Ba[...] 1526; 'Procopius Cæsariensis, De Rebus Gothorum,' Ba[...] 1531; 'Tacitus,' Basel, 1533; reprinted in 1544; 'L[...] Decades Tres,' Basel, 1535.

Among the original works of Rhenanus we may ment[...] —'Præfatio in Marsilii Defensionem Pacis pro Ludovico I[...] Imperatore, adversus iniquas Ecclesiasticorum Usur[...]tiones,' Basel, 1522. This work was published under t[...] assumed name of Licentius Euangelus, sacerdos. 'Il[...] provinciarum utrique Imperio cum Romano tum Constan[...]nopolitano servientis Descriptio,' published at Paris in 16[...] together with the 'Notitia dignitatum imperii Roma[...] 'Rerum Germanicarum,' libri iii., Basel, 1531: this w[...] has often been reprinted. The edition of Sturm (Ba[...] 1551) contains a good Life of Rhenanus. He also trans[...] several works from the Greek into Latin, such as some w[...] of S. Gregorius Nazianzenus, part of the writings of O[...]genes, in the edition of Erasmus, &c.

the rotation of the earth about the sun is not a mere probable hypothesis, as Copernicus had thought fit to announce it, but an incontestible truth, and asserts that if Aristotle himself were living, he would be the first to acknowledge his error, excited against him the ill-will of the leading advocates of the Ptolemaic system. This letter appeared in 1540, Danzig, 4to.; was reprinted the following year at Basel, and appended to the work of Copernicus, 'De Revolutionibus,' Basel, 1566; and to Kepler's 'Prodromus Dissertat.,' Tübing., 1596. He resumed his professorship in 1541-2; and in the latter year were published his 'Orationes de Astronomiâ, Geographia, et Physica,' Nürnb. He subsequently visited different parts of Germany, taught for some time at Leipzig, and died of apoplexy at Cashau, in the north of Hungary, 4th December, 1576. (Zedler.)

Rheticus has left an indisputable proof of extraordinary industry and devotedness to science in a posthumous work, entitled 'Opus Palatinum de Triangulis à Georgio-Joachimo-Rhetico cœptum, L. Valentinus Otho, principis palatini Frederici IV., electoris mathematicus consummavit, Neostadii in Palatinatu,' 1596, fol. The least important part of this work is the introductory treatise on Trigonometry, in nine books, of which the first four, relating to right-angled triangles, were written by Rheticus, and the other five, on oblique triangles, by his pupil Otho. They comprise four hundred and eighty-one folio pages, which, observes Delambre, might be compressed into ten.

As authors, Delambre declares that Rheticus and Otho were the most prolix and obscure that he had ever met with. After the introductory treatise follows a table of sines, cosines, tangents, cotangents, secants, and cosecants, to every ten seconds of the quadrant, and to a radius of 10,000,000,000. Nearly the whole of this extensive table, which must have been of inestimable value to the astronomer, was the work of Rheticus, though the contrary might be inferred from the statements of Montucla and Lalande. The sines were originally computed by him to fifteen places of figures, and were correct to the fourteenth, as was shown by M. Prony, in the fifth volume of the 'Mémoires de l'Institut;' but only the first ten were inserted in the 'Opus Palatinum.' The table of tangents and secants was not quite complete when Rheticus died. Those which were wanting were added by Otho. The whole were computed to ten places of figures, of which only the first eight could be relied on. Pitiscus subsequently computed the tangents and secants as far as eleven places of figures (Montucla says sixteen), which, with the rest of the table of Rheticus, he published in 1613, under the title of 'Thesaurus Mathematicus.'

It is to the labours of Pitiscus that Montucla ascribes most praise, designating them 'the most remarkable monument of human patience, the more meritorious as it was accompanied by so little glory,' which, observes Delambre, would be true if the name of Rheticus were substituted for that of Pitiscus, whom he considers to have been little more than the editor of the 'Thesaurus Mathematicus.' (See the *Astronomie Moderne*, ii., p. 34.) The only terms employed in the 'Opus Palatinum' to express the several functions of an arc, are base, perpendicular, and hypothenuse; the terms tangent and secant had not then been introduced, and the appellation sine, which had been generally employed by Müller and others, was rejected by Rheticus. The construction of the canon is understood to have commenced in the year 1540.

Rheticus had intended to publish two treatises in German on astronomy and philosophy generally, and had announced a work on chemistry, in seven books, none of which have appeared. In these his chief aim was to abolish hypothesis, and to rest exclusively on observation.

(Zedler, *Grosses Universal Lexicon*, xiv. 812; Kästner, *Geschichte der Mathematik*, i. 561-2; Delambre, *Astron. Mod.*, ii. 1-25; Weiss, *Biog. Univ.*, art. 'Joachim;' see also Adani *Vit. Philos. Germ.*; and Vossius, *De Mathem.*)

RHETORIC (ῥητορική) is a Greek word of similar import to the Latin oratory; but a rhetorician is a teacher of or writer on oratory, and an orator is one who practises the art; Demosthenes was an orator, Aristotle was a rhetorician, and Cicero was both.

English writers, in treating of rhetoric, appear generally to consider it the same as oratory, and perhaps it is difficult to make a distinction between them. Cicero's 'Orator,' 'De Oratore,' and 'De Claris Oratoribus,' are always called rhetorical works. Quinctilian (*Inst.*, ii. 14) speaks of persons who translated the Greek word 'rhetorice' into Latin by 'oratoria' and 'oratrix;' but he objects to the use of both these words, and adopts the Greek word, which, he says, Cicero himself employed to designate certain books (probably the two books 'De Inventione') which he had written on this art. What Quinctilian calls 'rhetorice' is discussed at length under ORATORY, and an account of Quinctilian's work on the same subject will be found under QUINCTILIAN. In the former article it is stated that the treatise of Aristotle on rhetoric is the oldest extant treatise on this art, and one of the most valuable books preserved from antient times. The present article seems to furnish a suitable occasion for giving a short account of Aristotle's work.

Aristotle begins by saying that rhetoric is the counterpart (ἀντίστροφος) of logic, and he defines it to be the faculty (δύναμις) of perceiving on any given subject what is best adapted to persuade. He divides rhetoric into three parts: Persuasion (πίστις, or rather πίστεις), Language or Expression (λέξις), and Arrangement (τάξις). His work consists of three books, of which the first and second treat of persuasion, and the third treats of expression and arrangement.

After premising some general remarks on rhetoric, he treats of persuasion as derived from enthymemes (ἐνθυμήματα). Having stated that there are three kinds of persuasion, the deliberative (συμβουλευτικόν), the demonstrative (ἐπιδεικτικόν), and the judicial (δικανικόν), and that, in reference to each of these, persuasion is both special (ἴδιαι) and general (κοιναί), c. 3, he discusses the subject of special persuasion in each kind: touching the deliberative he inquires whether it be useful, c. 4 to 8; touching the demonstrative, whether it be honourable, c. 9; touching the judicial, whether it be just, c. 10 to 15. He concludes the first book by stating and explaining the modes of producing persuasion without the art of rhetoric, c. 16.

In the second book he proceeds to say that, in reference to certain questions, special persuasion must be considered as depending on the character of the speaker, c. 1; and on the passions of the hearers, c. 2 to 13; as also on the general character of the hearers, such as their passions, their moral habits, their different ages and conditions in life, c. 17 to 19. He closes the discussion of special persuasion by viewing it in connection with questions common to the three kinds of persuasion, such as possibility, fact, futurity, and magnitude, c. 19. He then proceeds to persuasion considered generally and indefinitely, of which he mentions two kinds, example (παράδειγμα) and enthymeme (ἐνθύμημα), adding *gnóme* (γνώμη) as included in enthymeme, c. 20 to 26.

He commences the third book with the second part of rhetoric, namely, expression. He states what is necessary to constitute expression, c. 2 to 4; and describes its various forms, c. 5 to 9. He treats of elegance (τὰ ἀστεῖα), c. 10, 11; and represents the different kinds of expression, c. 12.

He then comes to the third part of rhetoric, which is arrangement. This, he says, consists necessarily of two parts, the proposition of any subject, and its confirmation; but there may be four parts, introduction (προοίμιον), proposition (πρόθεσις), confirmation (πίστις), and peroration (ἐπίλογος). He concludes the work by discussing these four parts of arrangement: introduction c. 14, 15; proposition, c. 16; confirmation, c. 17; peroration, c. 19.

Aristotle's *Rhetoric* is not only the best treatise upon this subject, but a model of profound thinking and reasoning for the investigation of various other subjects.

RHEUM, a genus of plants of the natural family of Polygonaceæ, of which the name is taken from the ῥέον of Dioscorides, and which includes the different species of plants which yield the stalks and root so well known by the name of rhubarb. It is doubted by some whether the root to which the name *rha* and *rheon* was applied by the Greeks was the same as that to which we now apply the name of rhubarb, because the descriptions of the former given by Dioscorides and Pliny do not apply to the latter. It is admitted however that our rhubarb was known to the later Greek physicians, as Alexander of Tralles and Paulus of Ægina, and there is no doubt that the Arabs were well acquainted with it; and it is remarkable that they quote *rheon* as the Greek synonyme of their *rawund*, which is rhubarb, and which they describe as being of various kinds, as Indian, Turkish, Chinese, and from Khorassan. From this it is probable that one kind may have become substituted for another as the communication with the East increased.

Long as rhubarb has been known, it is remarkable that the species of Rheum yielding it is yet unknown; this is in consequence of the best rhubarb, Turkey rhubarb, being only obtained by the Russians at Kiachta from the Chinese. That called Chinese may be the produce of the same, or of a different species, from the northern boundaries of that country. Dr. Royle, after reviewing the different accounts of the commerce of rhubarb, states:—'This would bring the rhubarb country within 95° of E. long., in 35° of N. latitude, that is, into the heart of Tibet. As no naturalist has visited this part, and neither seeds nor plants have been obtained thence, it is as yet unknown what species yields this rhubarb.' Sievers had previously said that his travels had satisfied him that as yet nobody, that is, no scientific person, has seen the true rhubarb plant. The Himalayan and Persian rhubarbs have alone been ascertained.

The different species of rhubarb are important plants, not only on account of the roots being so extensively employed, and so valuable for their medicinal qualities, but also on account of the stalks of the leaves being now so much employed, from their agreeable acidity, in making tarts, &c. As the species are all indigenous in cold parts of the world, that is, from the southern parts of Russia, Siberia, Tibet, the north of China, and the Himalayas, so they may all be grown in the open air of this country, and several are cultivated on account of their stalks. Some also, both in England and France, are cultivated on account of their roots, often for the purpose of adulteration. The genus Rheum is characterised by having an inferior petaloid sexpartite calyx, into the bottom of which the stamens, about nine in number, are inserted; anthers opening lengthwise; ovary superior, with a single erect ovule; styles three, reflexed; stigmas peltate, entire; fruit (achenium) three-cornered, winged, with the withered calyx at the base.

The species which are known and cultivated are the following:—

1. R. Emodi, Wallich, Australe of Don, is found in Kumaon; the root is a valuable medicine, though bearing hardly any resemblance to that of the shops. Stems much branched, 6 to 10 feet high, very thick below, gradually diminishing, and spreading into large panicles, and there rough, with minute warts. Leaves very large, cordate, acute, dull-green, but little wavy, very rough, covered with little hairs. Petioles very rough, furrowed, and very much narrower at the upper than the lower end. Panicles terminal, very long. Flowers blood-red, very small.

2. R. Webbianum, Royle, 'Illust.,' t. 99, Emodi of Meisner, found by Mr. Moorcroft at the height of 12,000 feet above the level of the sea, and by Dr. Royle on the Choor Mountain. Root-leaves large, long-stalked, rather downy above, veiny beneath, margin hairy. Axillary racemes clustered, terminal, panicled; pedicels in threes, twice as short as the ripe fruit.

3. R. spiciforme, Royle, 'Illust.,' t. 78, found on the northern face of the Himalayas. Leaves thick, leathery, cordate, blunt, red and netted beneath, and covered with stellate down on each side. Pedicels numerous, clustered, as long as the ripe fruit. The roots are lighter coloured and more compact than those of R. Emodi.

4. R. Moorcroftianum, Royle (Small-Stalked Rhubarb). Leaves and stems covered with short pubescence; petioles deeply furrowed; the stipules as long as the petioles, and very membranous; scales at the base yet longer, extremely thin, and, towards the summits, much torn. This species was found by Messrs. Moorcroft and Hearsay near the Niti Pass in the Himalayas, at an elevation of 12,000 feet.

5. R. leucorhizum, Pall. (nanum, Sievers; tataricum, Linn.). A small plant for the genus; the root is white and branched, though said to be equally efficacious with the best sorts. Radicle leaves about three, short stalked, from four to six inches long, and from five to nine broad; smooth on both sides, toothletted at the edge. Flowering stem about two inches high when in flower, afterwards becoming ten to twelve high.

6. R. rhaponticum, Linn. North of the Caspian. According to Guibour, cultivated largely near Lorient, in the department of Morbihan in France, at a place called from that circumstance Rheumpole. Leaves roundish, ovate, cordate, obtuse, but little wavy, very concave, even, very slightly downy on the under side. Panicles very compact and short, always rounded at the ends, and never lax. R. rhaponticum, hybridum compactum, and hybrid varieties of them, are the common garden rhubarbs, of which one is called R. hybridum.

7. R. undulatum, Linn. (rhabarbarum, Linn.). China and Siberia. Leaves oval, obtuse, deep green, with veins purp at the base, often shorter than the petiole, downy on ea side 'when young, looking as if frosted. Petiole dow blood-red, semi-cylindrical.

8. R. caspicum, Fischer (rhaponticum, Ledbour). In t Altai Mountains. Leaves ovate, acuminate, obtuse, date, inflexed at the base, thick, very wavy, glossy on upper but slightly downy on the under side. Petiole green, minutely downy.

9. R. compactum, Linn. Tartary and China. Le heart-shaped, obtuse, very wavy, deep-green, thick, smooth on both sides, glossy on the upper. Sinus n closed with parenchyma. Petiole green.

10. R. crassivernium, Fischer. Leaves heart-sha acuminate, obtuse, wavy, bullate, deep green, quite sm rather glossy above, ribs slightly coloured red, the ones above half an inch deep at the base. Petiole dull rounded, rather angular.

11. R. palmatum, Linn., generally thought to be source of the true officinal rhubarb. Near the great w China. Leaves roundish, cordate, half palmate; the lob natifid, acuminate, deep dull green, not wavy, but u and very much wrinkled on the upper side, hardly sca at the edge, downy on the under side. The flow stems are taller than those of any other species.

12. R. Ribes, seems to be so named from the Per name *ribas*, which is as frequently written *rewash*, which Elphinstone, Burnes, and other travellers notice being highly esteemed by the Persians, and of which stalks are prepared in a variety of ways, and consider great delicacy. For a fuller account of the localities racters, &c. of these various species, see Royle's *Ill Himal. Bot.*; Lindley, *Flora Medica*; and Pereira, *Elem of Materia Medica.*

RHEUM (*Rhubarb*), MEDICAL PROPERTIES OF. As the particular species which yields the officinal rhub and even the precise place of its growth, are not known varieties met with in commerce are here described, with attempting to assign them to any ascertained spe There are six well-marked varieties, viz. Russian or T key, Dutch-trimmed, Chinese, Himalayan, English, French. Of the first sort the greater portion at pre comes from St. Petersburg, and is denominated Musc Bokharian, or Siberian rhubarb, while a 'part has formed one of the imports from China into Bokhara, wh passing to Smyrna, it is known in Europe as Turkey r barb' (Royle, *Flora of the Himalaya*), which name it c monly bears in the shops. This kind varies much in and appearance, the pieces being cylindrical, sphe flat, or irregular, from two to three inches long, o three broad, and one to three thick. 'The smaller p are picked out, being preferred, while the larger piece the dust are employed for powdering.' Holes are remar in many of the pieces, of which one occasionally ext entirely through, the others only partially; the f having been made in order to suspend the piece in dr the others in examining the quality. This kind, and p bably the other sorts, is frequently worm-eaten, owing the ravages of a small beatle, sinondendrum pus (Kirby and Spence's *Entomology*, i., p. 252.)

Externally the pieces are covered with a bright yel coloured powder, which either results from the fricti the pieces during their passage to this country, or from process of rouncing (that is, shaking in a bag with powder rhubarb), previous to its exportation. The odour is str both of the root and fresh powder, peculiar, somewhat not pleasantly aromatic. When chewed, it feels gr owing to the presence of numerous raphides (or crystal oxalate of lime, which are present to the amount of betw 30 and 40 per cent.); it communicates a bright ye colour to the saliva, and has a bitter, slightly astringe taste, which to some persons is not unpleasant, as are in the habit of chewing rhubarb to obtain its to effects on the stomach; but this practice is objection from the yellow colour it imparts to the teeth and gums.

When the dust which covers the surface is remove exhibits a more or less reddish-yellow hue with white l interspersed, which form beautiful reticulations, best on a vertical section, while a transverse section exhibits star-like spots and depressions of a darker colour. T transverse fracture is uneven, the longitudinal still more 'The powder of genuine Russian rhubarb is of a brig yellow colour, verging to red, but as met with in the sh it is almost invariably mixed with the powder of English rhubarb,' which gives it a much lighter colour.

The analysis of this sort shows it to consist of—

Rhubarberine (or bitter principle of Pfaff)	16
Yellow colouring matter (of Henry)	9
Bitter extractive	14
Oxidized tannin	1
Mucilage	10
A substance extracted from the woody fibre	28
Oxalic acid	1
Woody fibre	14
Moisture, loss, odorous principle	3

The chief chemical distinction between this and English rhubarb is the presence in the latter of a principle termed *rhaponticin*, and 14 per cent. of starch, with a smaller portion of rhubarberin, of yellow colouring matter, and extractive: iodine furnishes a ready distinguishing test, for a 'decoction of Russian, Dutch-trimmed, or Chinese rhubarb becomes, with a solution of iodine, greenish-blue (iodide of starch); after a few minutes the colour disappears, and no iodine can be detected in the liquor by starch, unless nitric acid be previously added; a decoction of English rhubarb is rendered by a solution of iodine intensely blue (iodide of starch), the colour not completely disappearing by standing.' (Pereira.) This difference is clearly dependent on the much greater portion of starch existing in English rhubarb. Inferior rhubarb, or roots cut to resemble rhubarb, and sprinkled over with powdered turmeric, or dyed with it, may be detected by means of boracic acid, or any borates rendered acid, since the colour of genuine rhubarb, or paper dyed with it, is not affected by these re-agents, whereas turmeric-paper is reddened by them. Yellow ochre, with which black and worthless pieces are covered, or which is used to fill the holes in worm-eaten pieces, may be detected by heat, as it burns with a brownish red appearance, and exhibits the characters of a ferruginous earth.

Portions unusually white are occasionally found in the chests of Russian rhubarb, and are presumed to be specimens of *imperial rhubarb;* but nothing certain is known of its origin or relative value.

2. Dutch-trimmed rhubarb, called also by some writers Persian rhubarb, and Batavian, occurs in flat or round pieces, and is not much different in appearance from the preceding, but it reaches Europe through Canton and Singapore. It is said to be very liable to the attacks of a small coleopterous insect, Anobium boleti, and that the holes so made are stopped with yellow ochre.

3. Chinese or East Indian rhubarb, termed in commerce *half-trimmed or untrimmed* rhubarb, rarely presents an angular character, but occurs in rounds or flats. 'The best pieces are heavier and more compact than those of the Russian kind, and the odour is much less powerful and less aromatic.'

4. Himalayan rhubarb is not known as a commercial article in this country, nor is it even an article of large consumption in India, where it sells for only one-tenth of the best rhubarb, resembling in quality the Russian, and which is found in India. The finest Russian rhubarb might be introduced and cultivated in the territories of the East India Company, or, as Dr. Royle observes, 'a trade in rhubarb with Tibet or Western Mongolia might be established by means of the Tartars who resort to the hill fairs. This trade might easily be encouraged by the government purchasing all the rhubarb it requires, which might thus be employed for hospital use after crossing the frontiers, instead of, as now, after making a journey of 20,000 miles, or nearly the circuit of the globe.' (*Flora of the Himalaya.*)

5. English rhubarb occurs in two states, '*dressed or trimmed* so as to resemble the Russian kind, and *stick* rhubarb. The first is grown at Banbury in Oxfordshire, and is frequently used for the show-bottles in druggists' windows, and often sold in the streets of London for *Turkey rhubarb*, by persons dressed up as Turks. Stick rhubarb is sold in the herb shops, and is in long pieces.'

6. French rhubarb is not brought into this country.

What is termed *Monk's rhubarb* is not the produce of any species of *rheum*, but of the Rumex alpinus, which grows in Switzerland, Germany, and Mount Taurus, and is more astringent than purgative; it is mostly used by the monks of the Alps, or to adulterate the other sorts.

Large importations of rhubarb are made into this country, partly from Russia, but much more from the East Indies; but the greater part is for re-exportation. The quantity retained for home-consumption, and on which only a duty of one shilling per pound is paid, scarcely constitutes one-fourth of the entire amount.

Rhubarb presents the peculiarity of producing two opposite effects, according to the dose exhibited. In small doses it is tonic and astringent, in large doses purgative, but generally followed by constipation. It is moreover somewhat heating, and therefore unfit for the early stage of inflammatory diseases; on the other hand, its tonic properties render it eminently proper in the later stages of these diseases. In debility of the digestive organs, alone, or better in conjunction with other agents, it is a most valuable remedy; but it is very improper in the form of powder for very young children, as the insoluble woody fibre irritates their delicate stomachs, and contributes to produce that state o. irritation under which so many young children sink who are overdosed with domestic medicines. Dr. Reid, from large experience at a public dispensary, stated it as his deliberate opinion, that half the children which died in London under two years of age were killed by mothers and nurses dosing them with rhubarb and magnesia. A more rational proceeding is to regulate the diet of tender infants, especially of such as are not suckled by the mother or a wet nurse; above all, to avoid giving them stimulating drinks or raw fruits.

Several species of rheum, and garden varieties of them, are cultivated for the sake of the petioles of the leaves, which are much used to make tarts in spring. The cooling and gently aperient properties of these render them grateful and beneficial to most persons; but individuals prone to calculous complaints should carefully avoid them, and all vegetables which owe their acidity to oxalic acid, as the formation of the oxalate of lime, or mulberry calculus, may be the consequence of indulgence. This observation applies equally to the species of Rumex which are used as sorrel. [CICER ARIETINUM.] (Pereira's *Mat. Med.*)

RHEUMATISM (from ῥευματισμὸς, 'a defluxion'). It is probable that this term was originally adopted during the prevalence of the doctrines of the humoral pathology, when every disease attended with swelling was attributed to the flow of some morbid humour to the part affected. Before the year 1642, rheumatism and gout were usually described as one disease, under the name of arthritis; the distinction between the two is said to have been first accurately made by Bellonius, a physician who suffered much from rheumatism.' We shall first treat of articular rheumatism in its acute and chronic form, and then describe some of those affections which, from their greater resemblance to it than to any other disease, have been called rheumatic.

Acute rheumatism, called also rheumatic fever, has been so well described by Sydenham, that we make use of his own words: 'This disease,' he observes, 'happens at any time, but especially in autumn, and chiefly affects such as are in the prime of life. It is generally occasioned by exposing the body to the cold air immediately after having heated it by violent exercise or some other way. It begins with chilliness and shivering, which are soon succeeded by heat, restlessness, thirst, and the other concomitants of fever. In a day or two, and sometimes sooner, there arises an acute pain in some or other of the limbs, especially in the wrists, shoulders, knees; which shifting between whiles, affects these parts alternately, leaving a redness and swelling in the part last affected. In the beginning of the illness the fever and the above-mentioned symptoms do sometimes come together, but the fever goes off gradually, while the pain continues and sometimes increases.' Acute rheumatism varies considerably in intensity and duration; the patient may have considerable fever, and severe pain in nearly every joint, so as to render him perfectly helpless; or the fever may be slight, and the local inflammation limited to one or two joints. There is not always a relation between the severity of the local symptoms and the constitutional disturbance. The duration of this disease depends on the mode of treatment; it may be terminated in a few days, or may endure as many months; in nearly every case the general symptoms cease before the local inflammation is stopped. Acute rheumatism simply, is seldom if ever a fatal disease, but complicated with pericarditis, endocarditis, or pleurisy it is highly dangerous. It behoves us therefore in every case of rheumatism to be on our guard against these complications; they are so frequent and come on so insidiously, that a recourse to the aid of the stethescope should never be neglected. With respect to what is called chronic rheumatism, it may be either a continuance of acute rheumatism in a milder form, or may originate in this chronic, or, more properly speaking, subacute character. In either case all the characters of acute rheumatism are present, but in a less violent degree; thus, there is a quickened pulse, some increased heat of skin, a furred tongue, and loss of appetite and sleep, the febrile action undermines the general health, while the local inflammation, although indolent, disorganises the joints. This state of things may endure for an indefinite period, or the febrile symptoms may after a time disappear and the morbid action in the joints cease, not however without leaving behind them such ravages as require a special local treatment. Dr. Elliotson has distinguished chronic rheumatism into hot and cold: in the former, the joints affected are above the natural temperature of the other parts of the body, and are relieved by the application of cold; in the latter, the contrary is the case. Whether the pain of the joints is relieved most by hot or by cold applications, it is generally aggravated in cold moist weather, and diminished during an opposite condition of the atmosphere. The only diseases with which rheumatism can be confounded are gout and periostitis: for its distinction from the former of which see GOUT. The term rheumatic, whether properly or not, has been applied to various affections which have very little resemblance to one another, except in being attended with pain; rheumatic gout however is as significant and appropriate a name as could have been devised. It is a disease partaking so strongly of the characters both of gout and rheumatism, that it is impossible to say to which of them it belongs; it may be rheumatism attacking also the small joints, or it may be gout extending to the large; in either case the distinction is not of much importance, as the treatment is the same. When rheumatism is seated in the back, it is called lumbago, from 'lumbus,' the loin; when in the back of the neck, the patient is said to have a stiff neck, or a 'crick in the neck;' when in the head, one half only is usually attacked, and it is called hemicrania. When the pain occupies the more fleshy parts of the limbs, as the muscles or their aponeuroses, the term rheumatalgia is sometimes made use off. In this last-named affection there is neither redness nor swelling, and pain is experienced only when the muscles of the part affected are called into action. Many persons believe that the nerves themselves may be affected with rheumatism, and refer to sciatica and hemicrania as examples. In these cases the pain is generally of an intermittent character; but Dr. Elliotson is of opinion that this intermittence of pain is not peculiar to nervous rheumatism, but is met with also when the aponeuroses of muscles are the seat of the disease, which he believes to be the case in hemicrania. He thus describes hemicrania: 'It usually attacks one half of the organ (the head), and the pain generally comes on in the evening about six o'clock and continues very violently for a few hours. Occasionally when it is intermittent in this way, the parts are hot, swollen, and throb, and the eyes water, but in other cases this is not felt.' Many physicians of eminence deny that the above-named affections are rheumatic, and consider them to be of nervous origin; hemicrania and lumbago they call neuralgia, and rheumatalgia they designate by the term myositis. From this contrariety of opinion we may conclude that little is known respecting the structures actually affected in these varieties of rheumatism; of the morbid changes which they undergo we are likewise in equal ignorance. In the true or articular rheumatism it is the synovial membrane lining the cavity of the joints and the fibrous tissues external to them that principally suffer. The respective degree in which each of these structures is implicated, is not the same in every case. Thus, in one case we shall find the joints distended with fluid, the fluctuation of which is very perceptible to the hand; while in another there shall be swelling, but it will be more diffused and without fluctuation, showing that little or no effusion has taken place into the joint, but that the swelling results from the inflammation of parts external to it. This difference has led some persons to speak of rheumatism as fibrous and synovial, but inasmuch as it is not always easy to determine to which variety the case under examination may belong, and is besides of no practical importance, the distinction is not usually regarded. The fluid which is found in the joints may be either gelatinous or purulent, according to the severity of the inflammation. The synovial membranes which line them are red and thickened; the ligaments external to the joints are thickened and rigid, the limbs frequently contracted, and the muscles wasted. In rheumatic-gout there is often found a deposit of lithate of soda in the joints affected, a proof that, in many cases at least, this disease partakes more of the character of gout than of rheumatism. The appearances presented in the heart and its coverings, where this organ has been attacked, have already been described in the article HEART, DISEASES OF.

Causes of Rheumatism.—Among the causes which predispose to rheumatism must be placed an hereditary tendency and the age and temperament of the individual. The period of life most subject to acute rheumatism is from puberty to 35 years of age, and persons of full plethoric habit are said to be more liable to its attacks than those of an opposite temperament. It is supposed by many among whom may be cited the names of M. Andral (*Anatomie Pathologique*), M. C. Roche (*Dictionnaire de Médecine et de Chirurgie*), and Dr. Barlow (*Cyclopædia of Practical Medicine*), that an absolute or relative condition of plethora is essential to the development of rheumatism: and the blood, according to these authorities, may be either excessive in quantity or altered in quality. 'There are some individuals,' observes M. Andral, 'who naturally make a greater quantity of blood than others. When the blood-vessels contain a greater proportion of the nutritive fluid than is necessary to supply the demands of the different organs, the superabundant quantity becomes a permanent source of excitation to the solids, and at the same time the blood has a remarkable tendency to accumulate in different organs; so that in such a case the whole system is in a general state of excitation, and some of the organs may become the seat of local congestion of various degrees of duration and intensity.' In applying these doctrines to the disease we are considering, he observes, 'If we mark the symptoms and progress of acute rheumatism, we find that very often a well-marked febrile action, with a strong reaction, but without any symptom whatever of local affection, precedes the pain. In a word, there is first an inflammatory fever, and then rheumatism. Next observe the extreme mobility of the rheumatic pains. They run along, in a manner, wherever the blood is distributed; the application of leeches often removes the pain from one part, but it soon shifts to another, and not unfrequently it quits the articulating tissues and fixes on different internal organs, producing, by the derangement of their functions, symptoms more or less severe. It often happens that bleeding from a large orifice puts an end to the disease, as if, by diminishing the mass of blood, it proportionally diminished the stimulus that promoted all these shifting irritations.' It is then, when the body is in this predisposed condition, from any of the before-mentioned causes, that exposure to a continued draught of cold air or a shower of rain becomes the immediate exciting cause of an attack of rheumatism. There can be no doubt however that, besides this condition of plethora, which predisposes to disease generally, there must be a more specific predisposition to the particular disease we are treating of before rheumatism can be produced. Cold may be a cause, and so may be anything else that suddenly disturbes the balance of the circulation; but why the same agent should produce rheumatism in one case, bronchitis in another, pneumonia in a third, and so on, can only be explained by supposing that each individual has some particular organ or organs which are more prone to disease than other parts of his organization.

The treatment of rheumatism must chiefly have reference to the constitutional nature of the disease. Nearly all physicians, from Sydenham downwards, have concurred in the propriety of general blood-letting, the quantity of blood to be drawn depending upon the severity of the attack, the age and constitution of the patient, and the impression produced by this operation upon the disease. The celebrated physician just named was in the habit of taking blood to the amount of ten or twelve ounces, and repeating the evacuation every twenty-four or forty-eight hours, till the disease was subdued; bread and water poultices were applied to the inflamed joints, and abstinence from all stimulating food and fermented liquors was strictly enjoined. In St. Bartholomew's Hospital, phlebotomy to the extent recommended by Sydenham is seldom practised in acute rheumatism, Dr. Latham having observed that the disease is frequently not bettered by the operation, although the patient is considerably weakened.

This eminent physician is in the habit of prescribing a large dose of calomel, as ten grains, in the acute stage of the disorder, and if in twenty-four hours the amelioration is not decided, another similar dose is given; from personal observation of the effects of this treatment, we can pronounce it to be most successful. When the membranes of the heart are affected, local bleeding by leeches or cupping is resorted to, and the patient is brought under the influence of mercury. According to Dr. Elliotson, whether rheumatism be acute or chronic, the treatment should be exactly the same: 'You have only to make two distinctions,—to ascertain whether it is the inflammatory form of the disease: whether the parts are hotter than they should be, and heat does harm; or whether the parts are cooler than they should be, and heat does good.' In the one case he recommends antiphlogistic measures, and in the other stimulants; under the antiphlogistic measures, he comprehends bleeding and the administration of colchicum, the latter to be continued till it purges the patient. During the whole time of the treatment cold lotions are applied to the inflamed joints. In the chronic form of rheumatism the joints are kept hot with flannels and rubbed with stimulating ointments and liniments, while the ammoniated tincture of guaiacum, beginning with half-dram doses, is given three times a day. Dr. Elliotson also considers that mercury is occasionally useful in both kinds of rheumatism. Lumbago and sciatica are most successfully treated by cupping the loins and the parts over the course of the great sciatic nerve, followed by the application of blisters to the same regions, and a general antiphlogistic regimen. In hemicrania great relief is frequently obtained by the application of heat to the part affected, as in wrapping up the head in flannel. Should the pain evince a tendency to return every evening, a large dose of a narcotic should be administered just previous to the paroxysm, and if not relieved in two or three hours, a similar dose must be repeated; we are informed that one grain of stramonium for an adult frequently acts like a charm in this affection. In rheumatalgia, when the parts are not hot, and the pain is not increased by heat, acupuncture and shampooing have been found of great service.

Where the joints are stiff and contracted, from long-continued inflammation, warm bathing, combined with frequent and persevering exercise of them, have been attended with the most signal success.

(Sydenham, *Opera Medica*, 'Tractatus de Podagra et Hydrope;' Andral, *Anatomie Pathologique;* C. Roche, *Dictionnaire de Médécine et de Chirurgie;* Dr. Barlow, *Cyclopædia of Practical Medicine;* Dr. Elliotson, *Practice of Medicine*.)

RHIA'NUS, a Greek poet, was a native of Bena in Crete, and lived about the time of Eratosthenes. He was originally a slave who had a kind of superintendence over a palæstra, but he subsequently became a learned grammarian, and wrote several poems: one of them was a 'Ηράκλεια, consisting of four books. (Suidas, v. 'Ριανός; Athen., iii., p. 2.) Another of his poems, called Μεσσηνιακά, contained a poetical description of the second Messenian war, of which we probably possess the substance in the account given by Pausanias in his fourth book. (See especially c. 6; comp. Müller, 'Dor.,' i. 7, 9.) Other poems of Rhianus were the Θεσσαλικά, 'Αχαικά, and 'Ηλιακά. Athenaeus (xi., p. 499) also mentions epigrams of Rhianus.

The emperor Tiberius is said to have been very fond of the poems of Rhianus, and even to have imitated them. (Sueton., *Tiber.*, c. 70.) The few extant fragments of his works are collected in Brunck's 'Analecta,' in Jacob's 'Anthologia Græca,' in Gaisford's 'Poet. Græci Minor,' and separately in a little book by N. Saal, under the title 'Rhiani quæ supersunt,' Bonn., 1831. Compare A. Meineke's essay, 'Ueber den Dichter Rhianos,' in the 'Transactions of the Berlin Academy,' 1834.

RHIN BAS, a department of France on the eastern frontier, taking its name from the river Rhine (in French, Rhin), on the bank of which it lies. It is bounded on the north by the department of Moselle and the Rhenish portion of the kingdom of Bavaria; on the east by the grand-duchy of Baden, from which it is separated by the Rhine; on the south by the department of Haut Rhin; on the south-west by the department of Vosges; and on the west by that of Meurthe. Its form approximates to an oblong square or a parallelogram, extending from south by west to north by east along the Rhine, with a projecting portion on the north-west side extending westward across the chain of the Vosges. The greatest length is, from south-south-east to north-north-west, from the bank of the Rhine above Marckolsheim to the bank of the Sarre, above Sarreguemines, 68 miles, or along the bank of the Rhine from the same point to the neighbourhood of Lauterbourg, which is about the same distance. The greatest breadth is in the northern part, from the neighbourhood of Lauterbourg across the Vosges to the neighbourhood of Harskirch, 60 miles. The ordinary breadth however does not exceed 30 miles. The area is estimated at 1800 square miles, being scarcely equal to three-fourths of the average area of the French departments, and being rather greater than the area of the English county of Lancaster (1766 square miles), or rather less than that of Northumberland (1870 square miles). The population in 1831 was 540,213; in 1836 it was 561,851, showing an increase in five years of 21,638, or just about 4 per cent., and giving 312 inhabitants to a square mile. In amount of population it far exceeds the average of the French departments; in density of population it exceeds the average in the proportion of two to one. In both respects it very far exceeds Northumberland, but falls very far short of Lancashire. Strasburg, the capital, is a very short distance from the left bank of the Rhine, on the Ill, a small feeder of that river; 243 miles in a direct line east of Paris, or 294 miles by the road through Meaux, Château Thierry, Châlons-sur-Marne, Vitry, Bar-le-Duc, Toul, Nancy, Lunéville, and Phalsbourg: in 48° 35′ N. lat. and 7° 47′ E. long.

Surface; Geological Character; Hydrography.—The principal ridge of the Vosges is just beyond the western boundary, so that the western side of the department is occupied by the rugged highlands, covered with wood, which form the eastern face of that chain. The projection at the north-western side of the department crosses the ridge in one part so as to include both the ridge itself and the western face down to the valley of the Sarre. The mountain sides are diversified with precipitous rocks, and picturesque valleys watered by small streams, which flow ultimately into the Rhine, except a few which join the Sarre. The mountains are composed of sandstones, limestones, and marls, comprehended in the saliferous group of formations. The lowest member of the group is a coarse red-sandstone (*grès des Vosges*), bearing a close resemblance to the old red-sandstone conglomerate of Monmouthshire, and containing abundance of quartz pebbles, apparently derived from the ruins of the primary rocks which form the nucleus of the Vosges. The upper part of this formation is finer grained, so as to bear a close resemblance to the variegated red-sandstone (*grès bigarré*), extremely similar to the new red-sandstone of England, which rests immediately upon it. Upon this rests the muschelkalk, a light grey or smoke-coloured limestone, with partings of marl; and upon this rest the variegated marles (*marnes irisées*), which are occasionally interstratified with gypsum or limestone. By convulsions subsequent to the deposition of the grès des Vosges, a portion of that formation has been thrown up into bold craggy mountains, while the later formations rest upon the lower portions, several hundred feet below, at the foot of the escarpment.

From the eastern foot of the Vosges, a rich tract forming part of the valley of the Rhine extends to the bank of that river. This part is occupied by the tertiary formations. The immediate banks of the river are in many places marshy.

A very small quantity of coal is procured. There are three iron-works, in which are three forges for producing pig-iron, and eleven forges for the manufacture of wrought-iron. Charcoal is the fuel principally used.

The department belongs entirely to the basin of the Rhine. The greater part is included in the valley watered by that river, and the remaining part, which extends across the Vosges, is drained by the Sarre, which falls into the Moselle, and so ultimately into the R[illegible] The Rhine skirts the eastern boundary of the depa[illegible] this part about as broad as the Thames at I[illegible] number of small islands of sand or gr[illegible] course are very injurious to the navi[illegible] on by boats of from 20 to 25 tons. [illegible] rally wooded. The Rhine yields [illegible] cially trout, perch, salmon, carp, st[illegible] particles of gold are brought dow[illegible]

The principal feeder of the R[illegible] in the adjacent department of Haut Rhin, near the Swiss frontier, and flows northward, its course being for the most part parallel to the Rhine and a few miles west of it, so that it receives the mountain-streams which flow down the eastern slopes of the Vosges, and thus becomes a considerable river. Nearly 40 miles of its course are in this department, and through the whole of that distance it is navigable. It receives the Liepvrelle, the Scheer, the Andlau, the Eger, the Bruche, into which flows the Mossig, all from the Vosges; passes Schelestat, Benfelden, Erstein, and Strasburg; and joins the Rhine a few miles below the last-named place. It is used for the conveyance of the timber of the Vosges and the other productions of the country. One or two arms of this river branch off from it above Strasburg, and communicate with the Rhine.

The Zorn, which receives the Zintzel; the Moder, which receives another Zintzel; the Surbach, which receives the Eberbach; the Seltzbach; and the Lauter, all flow from the eastern face of the Vosges into the Rhine. The Surbach and the Lauter rise in the Bavarian territory, and the Lauter has its course on the frontier of France and Bavaria, which it separates from each other. The Moder and the Lauter, the longest of these streams, have each a course of about 45 miles; the Moder alone is navigable, and that for only 2 miles. The others are used for floating timber down from the mountains to the low country or to the Rhine.

The course of the Sarre within the department may be estimated at about 20 miles, for nearly 10 of which it is navigable.

There are two navigable canals. The most important is the great canal for joining the Rhône and the Rhine, formerly called Canal de Monsieur. This canal enters the department on the south side from the adjacent department of Haut Rhin, and, running northward along the valley of the Rhine, opens into the Ill just above Strasburg. The canal of the Bruche commences near the junction of the Mossig and the Bruche, and follows the valley of the latter river till its junction with the Ill just above Strasburg.

The official statement of the inland navigation of the department, in 1837, was as follows:—

	Miles.
Navigation of the Rhine . .	90
" Ill . .	51
" Moder . .	2
	143
Canal from the Rhône to the Rhine	33
Canal of the Bruche . .	13
	46

The number of Routes Royales, or government roads, on the 1st January, 1837, was seven; having an aggregate length of 206 miles, viz. 201 miles in good repair, and 5 miles out of repair. The principal road is that from Paris to Strasburg, which enters the department after passing Phalsburg (department of Meurthe), and passes through Saverne and Wasselonne. From Strasburg this road is continued across the bridge of Kell or Kehl on the Rhine into Germany. The road from Paris by Lunéville and St. Dié to Schelestat enters the department a short distance from the last-named town. A road from Colmar follows the course of the Ill, passing near Schelestat and through Benfelden to Strasburg; and another road from Neuf-Brisach follows the course of the Rhine, through Marckolsheim, to the same town. Two roads from Strasburg run northward along the valley of the Rhine to one near the river through Drusenheim, Beinheim, Seltz, and Lauterburg to Speyer (Spire) and Mayenz (Ments or Mayence) in Germany; the other, nearer the mountains, through Brumath, Haguenau, Soultz-sous-Forêts, and Weissemburg to Landau and Mainz. A government road crosses the Vosges from Haguenau to the small fortress of Bitche in the department of Moselle. The Routes Départmentales, or departmental roads, had at the same time an aggregate length of 390 miles; viz. 345 miles in good repair, 36 miles out of repair, and 9 miles unfinished. The bye roads and paths have an aggregate length of more than 4500 miles.

Soil, Agriculture, &c.—The soil of the mountains is rocky, and in great degree barren; that of the immediate bank of the river is marshy, but the flat which occupies the intervening space is rich and highly cultivated. About 450,000 acres, two-fifths of the whole area of the department, are under the plough. The produce in wheat is a trifle more than the average produce of the departments of France; but, from the density of the population, it is inadequate to the consumption of the inhabitants. The produce in rye, maslin or mixed corn (wheat and rye), and maize, is about half the average produce of the departments; and the produce in potatoes twice as great as the average. In oats the produce is small, and of barley and buckwheat scarcely any is grown.

Tobacco has been cultivated for two centuries, and, in some soils, is included with wheat and barley in a triennial rotation of crops. As early as the year 1718, the yearly produce of tobacco was about 80,000 cwts. Madder was introduced in the reign of the emperor Charles V., and is now so successfully cultivated, that the madder of Alsace has a preference in the Swiss, French, and English markets. The oleaginous seeds are grown, especially the poppy and the rape, the oil of which is used for domestic purposes in Alsace, Flanders, and Artois, in place of olive-oil. Hemp, which is much prized for cordage for vessels, is grown near Strasburg. There are several hop-gardens about Haguenau, the produce of which is sent over into Germany, and then re-imported into France as of German growth, the reputation of the German hops causing them to fetch a higher price. The agriculture of the department is however susceptible of much improvement; the agricultural implements are clumsy, except in the neighbourhood of Strasburg; and there are many articles of produce which deserve more extensive cultivation than they now receive.

The meadows comprehend about 140,000 acres, and the commons and open pastures are 50,000 more. The number of horses is nearly twice as great as the average of the departments: they are of a good breed: both oxen and horses are employed in agriculture. The number of cows and heifers far exceeds the average of the departments; but that of oxen and bulls is less than half the average. The number of sheep is comparatively small. There are swine and poultry, especially geese, whose livers are used in making the pies for which Strasburg is famous. The vineyards comprehend 30,000 acres: very little red wine is produced: the best white wines are those of Molsheim and Wolxheim; those of Mutzig, Neuviller, and other places are wines of the second class. The orchards and gardens cover about 15,000 acres. The woodlands are very extensive, amounting to nearly 300,000 acres. A considerable part of the timber is formed into small rafts, and floated down the Rhine to Mainz, where they are united, so as to constitute enormous rafts from 250 to 300 yards long, and 20 to 30 yards broad, conducted each by 300 or 400 men. A part of the timber is sawn into deals and planks in Holland. The abundance of timber supplies not only sufficient fuel for domestic purposes, but also furnishes some for manufactures. It is not however sufficient for the demand, and a considerable quantity of coal is imported to make up the deficiency of wood.

Divisions, Towns, &c.—The department is divided into four arrondissements, as follows:—

Name and Situation.		Area in Sq. Miles.	Population. 1831.	1836.	Communes.	[illegible]
Strasburg	East & Central	546	205,029	218,839	162	[illegible]
Saverne . .	W.	506	108,112	112,260	165	[illegible]
Schelestat .	S.	444	131,295	134,887	114	[illegible]
Weissemburg	N.	304	95,777	95,873	103	6
		1800	540,213	561,859	544	[illegible]

In the arrondissement of Strasburg are—Strasburg, population in 1826, 49,708; in 1831, 49,712; in 1836, 57,[illegible] [STRASBURG], on the Ill; Molsheim, pop. 3225; Mutzig, pop. 3551; and Dachtein, or Dachstein, on the Bruche; Wasselonne, pop. 3649 town, 4191 whole commune; Wangen or Vangen, and Westhoffen, pop. 2363; all on or near the Mossig: Brumath, pop. 3977 town, 4062 whole commune, on the Zorn; and Haguenau, pop. 8280 town, 9697 whole commune; Bischwiller, pop. 5927 [BISCHWILLER], and Drusenheim; all on the Moder, the last at its junction with the Rhine. Molsheim, or Moltzen, is in a wine-growing district at the eastern foot of the Vosges: it is a tolerably well-built town. The townsmen manufacture heavy iron goods, tools, cutlery and other hardwares, and paper; weave cottons and coarse linens; and trade in corn and wine. The manufacture of hardware was introduced in 1817, and workmen were engaged from the grand-duchy of Berg. Mutzig is in a valley near the foot of the Vosges: some of the townsmen are engaged in a government manufactory of fire-arms. Wasselonne has manufactures of woollen yarn, woollen hose, paper, and leather: there are bleach-grounds for linen. Two fairs are held in the year. There are extensive quarries near the town of freestone for building, and of a stone which approaches to marble in its susceptibility of polish. Pottery is made at Westhoffen. Brumath was known to the Romans by the name of Brucomagus, or Brocomagus: it is mentioned by Ptolemy and Ammianus Marcellinus, and in the Itinerary of Antoninus: the medals, sculptured stones, and urns, which have been found abundantly, show that the Romans were fixed here. It was the scene of conflict between the Imperialists and the French in the year 1793. Haguenau was founded by the emperor Frederick Barbarossa, and was one of the Imperial cities of Alsace: its privileges were abolished after the conquest of Alsace by Louis XIV. In 1675 and 1705 it was besieged by the Imperialists: in the second siege they were successful, but the town was retaken by the French soon after. In 1793 the Imperialists and Prussians were defeated near the town by the French, who carried their lines and entered the town. Haguenau is surrounded by old walls, strengthened by towers and a ditch. It has manufactures of cotton yarn and calico; and of woollen cloth, cordage, soap, pitch, tiles, pottery, and earthenware. There are several oil-mills, plaster-mills, madder-mills (a great quantity of madder is grown round the town), tan-yards, and breweries. There are four yearly fairs for cattle and general merchandise. The town has five churches and a Jews' synagogue: a college or high school, a military hospital, and a house of correction for women. Drusenheim, or Druzenheim, is fortified, there is a wooden bridge over the Zorn near the town. There is one yearly fair for hardwares, woollen cloths, and silks.

In the arrondissement of Saverne are Saverne, pop. in 1831, 5106; in 1836, 5352; and Hocfelden or Hochfelden, pop. 2253, on the Zorn; Marmoutier, pop. 2450 town, 2735 whole commune, between the Zorn and the Mossig; Neuwiller, near the Zintzel, which flows into the Zorn; Bouxwiller, pop. 3756, and Petite-Pierre, between the Zintzel (tributary of the Zorn) and the Moder; Ingwiller, pop. 2071, and Pfaffenhofen, on the Moder; Lichtemberg, between the Moder and its tributary the Zintzel; and Saar-Union, pop. 3531, Saarwerden, and Harskirch, on or near the Sarre, in the country west of the Vosges. Saverne was a post of some importance in the time of the Romans, who called it Tabernae. Julian, while he held the command of Gaul, repaired the place and strengthened it, in order to prevent the Germans, with whom he was at war, from penetrating into the interior. It belonged in the middle ages successively to the bishops of Metz and Strasburg, and was accounted to be a place of strength; but in the Thirty Years' War, and in that which preceded the peace of Nimeguen, it was repeatedly taken and retaken: the fortifications were razed in 1697. The town stands on the Zorn, at the eastern foot of a steep and high mountain, one of the Vosges. The chief building is the former palace of the bishops of Strasburg, who used to spend their summers here. The townsmen manufacture hardwares, hosiery, and leather; and there are some breweries. The surrounding district is fertile in corn, wine, and pasture: considerable trade is carried on in wood, which is floated down the river. There are three yearly fairs. Saverne has a subordinate court of justice, some fiscal government offices, a college or high school, and an hospital. Marmoutier is a tolerably well-built town, surrounded by an old wall. The townsmen manufacture pottery, tiles, and bricks; there are breweries and bleach houses or bleach-grounds for linen; and a considerable trade in cattle is carried on. Bouxwiller is a busy place: the townsmen are engaged in weaving fustians, linens, and other goods, and in manufacturing hats: they have drying-houses for madder, bleach-grounds, and breweries. There are large works for making vitriol, sulphuric acid, ammonia, and other chemical preparations. There are three yearly fairs. Petite-Pierre is a place of strength amid the defiles of the Vosges: some hosiery is manufactured. Ingwiller has manufactures of madder, potash, starch, soap, snuff, cordage, and hosiery. There are dye-houses and bleach-grounds: there are three yearly fairs for corn and cattle. Lichtemberg is situated adjacent to the glacis of a small fort placed on a height in the midst of a wood. Saar-Union, or Sarre-Union, is divided by the Sarre into two parts: Bouquenom, on the right bank, and Neuf Saarwerden, or Sarrewerden, on the left. There are manufactures of cotton goods, embroidery, leather, and glass; also some dye-houses. The town has a college or high school. The remains of an old castle may yet be seen. Saarwerden, or Sarrewerden, distinguished as Vieux (old) Saarwerden, is so near to Saar-Union, as almost to form a suburb of it, but must not be confounded with Neuf-Saarwerden, which is an integral part of that town. Harskirch has some manufactures of worsted stockings and other woollen fabrics, soap, potash, and tiles: there are some dye-houses and a copper-foundry.

In the arrondissement of Schelestat are Schelestat, pop. in 1826, 9600 commune; in 1831, 9384 town, or 9646 commune; in 1836, 9700 commune [SCHELESTAT]; Benfelden, and Erstein, pop. 3472 town, 3613 whole commune, on the Ill; Marckolsheim, pop. 2265 town, 2344 whole commune, and Rhinau, on or near the Rhine; Châtenois, pop. 3318 town, 3867 whole commune, on the Liepvrelle; Villé and Dambach, pop. 3454 town, 3507 whole commune, on the Scheer; Andlau and Barr, pop. 3720 town, 4514 whole commune [BARR], on the Andlau or its tributaries; Bersh Obernai, pop. 4634 town, 4795 whole commune, and Niedernai, on or near the Eger; and Rosheim, pop. 3683 town, 3772 whole commune, between Obernai and Molsheim. At Benfelden considerable business is done in the tobacco and hemp grown round the town. At Erstein, cotton hosiery, snuff, cordage, tiles, and pottery are made; and there are dye-houses and bleach-houses or grounds for linen: two fairs are held in the year. Marckolsheim has manufactures of linen, breweries, potteries, tile and brick yards. Trade is carried on in hemp and tobacco. Muslins, calicos, coarse linen for wrappers, and paper, are made at Châtenois; and leather, tiles, and hosiery at Villé, where there are also bleach-grounds for linen. At Ober-nai there are copper-works. This town and Nieder-nai are sometimes called respectively Ober and Nieder Ehnheim. At Rosheim, woollen and cotton hose are made, cotton woven, and linen bleached. There are two yearly fairs.

In the arrondissement of Weissemburg are Weissemburg, pop. in 1826, 6146; in 1831, 6097; and in 1836, 5575; and Lauterbourg, pop. 2649, on the Lauter: Soultz-sous-Forêts, pop. 1968; and Seltz, pop. 2183 town, 2263 whole commune, on the Seltzbach; Warth, and Beinheim, pop. 1545, on the Surbach; and Reichshoffen, pop. 2536 town, 2661 whole commune, on the Zintzel, which joins the Moder. Weissemburg, or Wissemburg, is a fortress of considerable strength, and is connected with the 'lines' of Weissemburg, works constructed along the bank of the Lauter to cover this part of France. It was a free imperial town, and was dismantled by Louis XIV., when ceded to him by the peace of Ryswick: its fortifications have however been since reconstructed. It was taken by the Austrians in 1744 and 1793, but was each time retaken. There are several government offices, a Catholic and a Lutheran church, a Jews' synagogue, a college, and an almshouse. Hosiery, straw hats, earthenware, pottery, soap, and leather are made; and there are breweries. Lauterburg is also fortified: it has two churches, a synagogue, two hospitals (one of them a military hospital), ropewalks, breweries, and potash manufactories. At Soultz-sous-Forêts, pottery and pitch are made; the neighbourhood yields good wine, and there is a brine-spring near the town. Seltz is celebrated for its mineral waters, of which 30,000 bottles are sent yearly to different parts. At Reichshoffen are iron-works and a paper-mill. Much madder is grown round the town. At Niederbronn near Reichshoffen are iron-works and paper-mills; also some mineral springs.

The population given above, when not otherwise described, is that of the whole commune, and from the census of 1831.

The department is one of the most industrious in France; the principal manufactures have been noticed in describing the towns. The inhabitants are chiefly of German origin and speak a corrupt German dialect, except in the towns, where French is spoken. The majority are Protestants, either of the Lutheran or Reformed churches; and Strasburg is one of the chief places of education for the Protestant clergy. The number of Roman Catholics is considerable, and there are some Baptists and some Jews. Education is more diffused than in most parts of France: of the young men enrolled in the military census of 1828-29, sixty-two in every hundred could read and write: the average of the departments being less than forty in the hundred.

This department, with that of Haut Rhin, constitutes the diocese of Strasburg, the bishop of which is a suffragan of the archbishop of Besançon. It is in the jurisdiction of the Cour Royale of Colmar, and of the direction of the Académie Universitaire of Strasburg. It belongs to the fifth military division, the head-quarters of which are fixed at Strasburg, and it sends six members to the Chamber of Deputies.

At the period of the Roman conquest this department was occupied by the Nemetes and the Tribocci, two of the German nations which had settled in Gaul under Ariovistus. The part west of the Vosges (the Vogesus or Vosegus of the Romans) was included in the territory of the Mediomatrici, a Belgic nation. In the Roman division of Gaul the department was at first comprehended in the province of Gallia Belgica; and upon the dismemberment of this province, in that of Germania Superior; except that part which lies west of the Vosges, which, on the further subdivision of Belgica, was included in Belgica Prima. Several towns mentioned in Roman writers or documents were within its limits. Argentoratum occupied the site of the modern Strasburg, a corruption of Stratæ-burgus, or Stratz-burg, a name as early as the time of Gregory of Tours. The Tabernæ of the Itinerary of Antoninus and the Peutinger Table is Saverne; the Brocomagus of Ptolemy, Ammianus Marcellinus, and the Antonine Itinerary, is the modern Brumath. The Concordia of the Itinerary of Antoninus may be fixed at Alt-stat (or old town), on the Lauter below Weissemburg: the Saletio of the same authority (Ammianus Marcellinus writes it Saliso) was at Seltz on the Rhine, where the widening of the bed of the river has carried away part of the site of the town: the Helvetus of the Itinerary (called Helcebus by Ptolemy) may be fixed at a place called Ell, on the Ill near Benfelden; and the Argentovaria of the same authority was close on the border of the department near Marckolsheim.

On the overthrow of the Roman empire this part of Gaul was occupied by the Alemanni, Allemanni, or Allemans [ALEMANNI], but on the defeat of this nation by Clovis, in the great batte of Tolbiac or Zulpich (near Cologne), A.D. 496, it passed into the hands of the Franks. In the division of the empire of Charlemagne, it was included in Germany, and continued long to be a part of the empire. The name of Alsace is derived from El-sass, a very antient German name, the first part of which is the name of the river (Ill, antiently El or Hel) which waters the country. Elsass was Latinized into Elisatium and Alsatia. Under the successors of Clovis, Alsace was a duchy, and retained that designation even after the jealousy of Pepin le Bref suppressed the dignity of duke of Alsace. Towards the close of the ninth century Alsace was successively possessed by Hugues, an illegitimate son of Lothaire, king of Lorraine [LORRAINE], and Zwentibold, a natural son of Arnulph, or Arnoul, king of Germany. In the tenth century the duchy was permanently revived and held as a beneficiary dukedom (usually in conjunction with that of Suabia) until near the close of the eleventh century, when it became hereditary. Alsace comprehended what now constitutes the departments of Haut Rhin and Bas Rhin. The hereditary duchy was held by princes of the imperial house of Hohenstaufen from the year A.D. 1080, until the death of Conradin, A.D. 1268. Alsace had long previously, while under its dukes, been divided into the two counties or landgraviates of Nordgaw, or Basse Alsace, and Sundgaw, or Haute Alsace, the former of which was in the latter half of the fourteenth century united to the bishopric of Strasburg. These counties continued, after the extinction of the duchy, until the cession of Alsace to France. [ALSACE.] Several districts of Alsace were however independent of the counts or landgraves, and were under their own lords, especially under the bishops of Strasburg; and several of the towns were free Imperial towns, as Haguenau, Rosheim, Schelestat, Weissemburg, and Strasburg, in this department; Colmar, Münster, and others, in that of Haut Rhin: and Landau, now in the Bavarian territories.

RHIN, HAUT, a department of France, on the eastern frontier, bounded on the north by the department of Bas Rhin; on the east by the grand-duchy of Baden in Germany, from which it is separated by the Rhine; on the south by the territories formerly belonging to the bishopric of Basel, now incorporated with the canton of Berne in Switzerland; on the south-west by the department of Doubs; and on the west by the departments of Haute Saône and Vosges. Its form approximates to a parallelogram, having its greatest extent from north to south. The length of a line drawn from the north-western corner of the department to the frontier of Switzerland near Delemont is 64 miles; the length of a second line drawn at right angles to the first from the south-western corner to Huningue on the Rhine, is 36 miles. The area of the department is estimated at 1572 square miles, which is about two-thirds of the average area of the French departments, and about the area of the English county of Kent. The population, in 18.. was 408,741; in 1831, 424,258; and in 1836, of 447,01.., showing an increase in the five years from 1831 to 1836 of 22,761, or rather more than five per cent., and giving ... inhabitants to a square mile. In amount of population it is considerably above the average of the French departments, and in density of population very far exceeds them; it is exceeded however in both respects by the English county with which we have compared it. Colmar, the chief town, is on the Lauch, a branch of the Ill, 232 miles in a straight line east by south of Paris, or 290 miles by the road through Meaux, Château-Thierry, Châlons-sur-Marne, St. Dizier, Bar-le-Duc, Nancy, Lunéville, St. Dié (or Diey), and Schelestat; in 48° 4′ N. lat. and 7° 23′ E. long.

This department, like that of Bas Rhin, is included between the crests of the Vosges on the west and the banks of the Rhine on the east; its western side is consequently mountainous, while on the east it subsides into the valley of the Rhine. Some of the mountains, called, from their rounded forms, 'ballons' (balls), are lofty. Le Ballon d'Alsace, at the junction of the three departments of Haut Rhin, Haute Saône, and Vosges, has an elevation of 4121 feet, and Le Ballon de Guebwiller, about six or seven miles west of the town of Guebwiller, has an elevation of 4698 feet. The southern portions of the department are covered by the ramifications of the Jura. The highest summits of the Vosges are composed of granitic or other primitive rocks; in the neighbourhood of Giromagny, south of the primitive district, are the sandstones, limestones, and other formations of the carboniferous system. On the east of the primitive formations, on the lower slopes of the Vosges, are the formations of the saliferous system, including, in descending order, the variegated marls, the muschelkalk, the variegated sandstone, and the sandstone of the Vosges; and resting upon these, the oolitic series of formations, which also compose the mass of the Jura. The eastern side of the department, from the foot of the Vosges to the Rhine, is occupied by the tertiary formations. In 1834 there was only one small coal-mine in the department. Granite, porphyry, marble, rock crystal, good freestone, and gypsum are procured; and there are several mineral springs, of which those of Soultzmatt, about ten miles south-south-west of Colmar, are the most important.

Malte-Brun (3rd edit., Paris, 1832) enumerates among the mineral productions of the department, iron, copper, lead, and arsenic; but if his statement is correct, the working of the lead and copper mines must have been given up, as they do not appear in the official reports of the Direction Générale des Ponts et Chaussées et des Mines for 1835. (*Statistical View of the Mining Industry of France*, by G. R. Porter, Esq.; *presented to the British Association for the Advancement of Science*, 1838.)

There were, in 1834, twelve iron-works with five furnaces for making pig-iron, and seventeen forges for the manufacture of wrought-iron. Charcoal was the fuel chiefly if not wholly employed.

The department belongs chiefly to the basin of the Rhine. The Rhine has a considerable breadth, and an average depth of ten to twelve feet The numerous islands in the channel, formed of sand or gravel, are a serious obstruction to the navigation. The various streams which flow from the Vosges are received by the Ill, which, rising in the Jura just within the southern boundary of the department, has a northern course parallel to the Rhine, which it joins below Strasburg, in the adjacent department of Bas Rhin. [RHIN, BAS.]

The navigation of the Ill commences at the junction of the Lauch, close to Colmar; but it is used for floating timber above that point. The Lauch and the Fecht, which join the Ill, are used for floating timber. The Largue, which rises in the Jura, has been made a feeder of the canal from the Rhône to the Rhine. The south-western part of the department belongs to the basin of the Rhône, and is watered by the Halle, the St. Nicholas, and the Savoureuse, which fall into the Doubs. None of these rivers are navigable.

The only canal in the department is that which unites the Rhône (by its tributary the Saône) with the Rhine. This canal enters the department near the junction of the little rivers Halle and St. Nicholas, and runs north-east along the valley of the St. Nicholas to the summit level near Dannemarie; from thence it runs still north-east partly along the valley of the Ill to the basin near Mühlhausen, from whence a branch proceeds to join the Rhine at Huningue near Basel, while the main branch runs northward between the Ill and the Rhine into the department of Bas Rhin. [RHIN, BAS.] This canal was for some time called Canal de Monsieur, but is now more commonly designated from the rivers which it unites.

The inland navigation of the department is officially given in the 'Statistique de la France' as follows: Rhine, 48 miles; Ill, 10 miles; total navigable rivers 58 miles; canal from the Rhône to the Rhine 73 miles; total navigation 131 miles.

The department contains seven Routes Royales, or government roads, having an aggregate length of 215 miles; of which, on January 1, 1837, 183 miles were in good repair, and 32 miles out of repair. The principal roads are those from Paris to Huningue, to Mühlhausen, and to Colmar. The road to Huningue enters the department between Lure and Belfort or Béfort; and passes through Belfort, Dannemarie, and Altkirch, to Huningue. The road to Mühlhausen crosses the Vosges into the department near the source of the Moselle, and passes by St. Amarin and Thann to Mühlhausen, from whence it is continued to Basel. The road to Colmar enters the department on the north near Schelestat, and runs by Guemar to Colmar. A road from Strasburg runs along the valley of the Rhine by Neuf-Brisach to Basel; and another road runs from Colmar by Hallstatt, Pfaffenheim, Rouffach, and Cernay to Belfort. The departmental roads have an aggregate length of 233 miles, of which, on Jan. 1, 1837, 147 miles were in good repair, 56 miles were out of repair, and 30 miles were unfinished. The bye-roads and paths have an aggregate length of 1350 or 1400 miles.

The soil of the department is stony and barren along the bank of the Rhine and in the Vosges; the central part is more fertile; and even amid the mountains there are some valleys of eminent fertility, as those of Giromagny, Masvaux, St. Amarin, and Munster. Cultivation is carried on with great care. Of the whole area of the department, which is above 980,000 acres, nearly 390,000 acres (or about two-fifths) are under the plough: the kinds of grain chiefly cultivated are wheat, barley, and oats: of barley, the produce is considerably above the average of the departments; in wheat and oats it is considerably below the average. In rye and maslin (wheat and rye mixed), and still more in maize and buckwheat, the produce is very far below the average; and in 1827 (when Dupin published his 'Forces Productives, &c. de la France') the cultivation of the potato was scarcely known. The whole grain harvest is by no means equal to the supply of the population, and a considerable quantity of corn is brought in from other departments.

The meadows, which are very rich, amount to 130,000 acres, and the heaths and open pastures to above 70,000 acres. The number of horses, taken absolutely or with relation to the number of the inhabitants, is below the average of the departments; but as compared with the area of the department, it is above the average: the number of horned cattle is above the average in every respect; the number of sheep is comparatively small, and the growth of wool altogether inadequate to the demand: the proportion of Merinos is however unusually great. The vineyards cover about 28,000 acres: the growth of wine is about equal to the consumption: the red wines are all of ordinary quality; but several of the white wines, as those of Guebwiller, Turckheim, Ribeauvillé, Thann, Pfaffenheim, and other places, are very good. The orchards, which cover nearly 15,000 acres, are very productive, especially in cherries, from which an excellent kirschenwasser is made. Pulse, hemp, flax, tobacco, and madder are grown. The woodlands comprehend above 280,000 acres, chiefly amid the Vosges. The abundant supply of wood furnishes fuel for the various manufactures of the department. It is floated down the streams which flow into the Ill or the Doubs.

The department is divided into three arrondissements, as follows:—

Name.	Situation.	Area Sq Miles.	Communes.	Cantons.	Pop. in 1831.	Pop. in 1836.
Colmar . .	N.	654	139	13	189 589	198,403
Altkirch . .	S.E.	442	159	6	118 513	127,465
Belfort . .	S.W.	476	191	9	116,156	121,151
		1,572	489	28	424,258	447,019

The number of cantons or districts, each under a justice of the peace, appears by a later return to have been increased to twenty-nine.

In the arrondissement of Colmar are the following towns. Colmar, pop. in 1831, 15,131 for the town, or 15,442 for the whole commune; in 1836, 15,958 for the commune [COLMAR]; Guebwiller, pop. 3451 for the town, 3637 for the whole commune: Rouffach, pop. 3900 for the town, or 3979 for the whole commune; Pfaffenheim, pop. 1842; Gueberschwihr, pop. 1608 for the town, or 1635 for the whole commune; Hallstatt, Hertisheim, and Eguisheim, pop. 2162 for the town, or 2183 for the whole commune, on or near the Lauch: Ensisheim, pop. 2335 for the town, or 2568 for the whole commune; and Sainte-Croix-en-plaine, pop. 1703 for the town, or 1729 for the whole commune, on or near the Ill; Neuf-Brisach, pop. 1975 for the town, or 2005 for the whole commune, between the Ill and the Rhine: Bollviller, between the Thann (a feeder of the Ill) and the Neugraberbach (a feeder of the Lauch); Soultz, pop. 3594 for the town, or 4016 for the whole commune, on the Neugraberbach; Soultzmatt, pop. 2830 for the town, or 3139 for the whole commune, on the Ombach (another feeder of the Lauch); Münster, pop. 4002 for the town, 4340 for the whole commune; Wihr-au-val; Wintzenheim, pop. 3003 for the town, or 3245 for the whole commune; Turckheim, pop. 2728 for the town, or 2736 for the whole commune; Ingersheim, pop. 1995; and Guemar, on or near the Fecht: Kaiserberg, or Kaysersberg, pop. 2896 for the town, or 3053 for the whole commune; Kientzheim; Ammerschwihr, pop. 2137; and Sigolsheim, on or near the Weiss (a feeder of the Fecht): Riquewihr, pop. 1716 for the town, or 1931 for the whole commune, between the Weiss and the Strengbach (another feeder of the Fecht); Ribeauvillé, pop. 6021 for the town, or 6558 for the whole commune, on the Strengbach; Sainte-Marie-aux-Mines, pop. 5918 for the town, or 9961 for the whole commune, on the Liepvrelle; Saint Hippolyte, pop. 2304 for the town, or 2414 for the whole commune; and Ober-Bergheim, near the northern boundary of the department. Scarcely another arrondissement in France contains so many towns. Guebwiller contains a handsome church, erected in the middle of the last century: the townsmen spin cotton-yarn, weave stockings, gloves, caps, handkerchiefs, calicos, cotton prints, printed shawls, and woollen cloths, and manufacture nails, currycombs, potash, and refined sugar. Rouffach is a walled town, and in the middle ages suffered much from the wars. The townsmen are engaged in spinning cotton-yarn and weaving cottons: they have five fairs in the year. Near the town is the castle of Isemburg, where some of the Frankish kings of the Merovingian race resided. Ensisheim, which is a tolerably well-built town, is also walled and surrounded with a ditch: it has a town-hall of Gothic architecture, and an ex-Jesuits' college, now converted into a poorhouse or house of correction. It was formerly a place of considerable importance, capital of the district of Brisgau, of the Black Forest, and of the Forest towns. In the Thirty Years' War it was repeatedly taken and retaken. The townsmen spin woollen yarn. Neuf-Brisach, or New Brisach, is of importance only as a place of strength: it was built by Louis XIV., to serve as a check to the fortress of Alt-Brisach (Old Brisach) in Baden, on the opposite side of the Rhine, and was fortified by Vauban on the most improved principles. The streets are straight, and the houses regularly built, but low, so as not to be visible outside the fortifications. Bollviller has some cotton-manufactures, and one of the most extensive nursery-grounds in France. It is especially rich in vines, fruit-trees, shrubs, and exotics. Soultz has manufactures of silk ribbon: there is a yearly fair. Soultzmatt has mineral waters, the most frequented in the department; the townsmen spin cotton-yarn, and weave muslins and linens. Münster owes its origin to a Benedictine abbey, founded in the seventh century. It was antiently fortified, and suffered much in the Thirty Years' War. The townsmen are engaged in the manufacture of cottons, plain and printed, muslins, and paper; and carry on trade in cattle, butter, cheese, and kirschenwasser: the master manufacturers are honorably distinguished by their care for the instruction of their workmen. Cottons and woollen goods are manufactured at Wintzenheim, and peat is dug in the neighbourhood. Turckheim, one of the free cities of Alsace, was signalised by a victory of Turenne over the Imperialists, A.D. 1675: it is a small ill-built town: the townsmen trade in the wine of the neighbourhood, which is in good repute. Kaiserberg, founded by the emperor Frederick II., who surrounded it with walls, was antiently a free imperial city. It was repeatedly taken and retaken in the seventeenth century. The town is well built: the manufacture of cotton-yarn, of calicos and other cotton goods, and of machinery for spinning cotton, is carried on. The neighbourhood of this town and of Ammerschwihr produces excellent wines. At Ribeauvillé, cotton handkerchiefs and other cotton goods are manufactured: near the town are the ruins of the castle of Ribeaupierre. Sainte-Marie-aux-Mines (in German, Mariakirch, or Markirch), is, next to Colmar, the most important place in the arrondissement: it is near one of the passes of the Vosges, in an agreeable situation: the Liepvrelle divides it into two parts. It derives its name from the copper and lead mines formerly worked in the neighbourhood, but the working of these has been gradually given up. The chief occupation of the townsmen at present is the manufacture of cotton and woollen yarn, of linens, woollens, and cottons, including handkerchiefs and printed calicos, and of leather and paper. There are extensive bleaching-grounds and some dye-houses. The town has a chamber of manufactures. There are two yearly fairs. St. Hippolyte is defended by a strong castle: it has an hospital.

In the arrondissement of Altkirch are Altkirch, pop. in 1831, 2724 for the town, or 2819 for the whole commune; in 1836, 3028 for the commune; Ferette; and Mühlhausen, pop. 13,187 for the town, or 13,300 for the whole commune [MUHLHAUSEN], all on or near the Ill: Huningue or Huningen, and Gros Kembs or Kemps, on the Rhine; and Landser, between the Ill and the Rhine. Altkirch was built early in the thirteenth century by one of the counts of Ferette. There are some antient towers yet standing. The townsmen manufacture leather, and there is a monthly fair for cattle. The town has a subordinate court of justice and a high school. Ferette has the ruins of an old castle: eight fairs are held in the town in the year. Huningue, or Huningen, was originally a fortress, constructed by order of Louis XIV., and fortified by Vauban: it had barracks for 4000 men. In 1814, and again in 1815, it was besieged by the allies; on the last occasion it was bravely defended by a mere handful of men against a considerable Austrian army: it was however obliged to capitulate, and the fortifications were destroyed at the solicitation of the citizens of Basel, within cannon-shot of which town Huningue is situated.

In the arrondissement of Belfort, or Béfort, are Belfort, pop. in 1831, 4537 for the town, or 5753 for the whole commune; in 1836, 5687 for the commune [BEFORT]; Giromagny, pop. 1603 for the town, or 2166 for the whole commune: Delle, on the Halle; Dannemarie, near the Largues; Massevaux, pop. 2531 for the town, or 3053 for the whole commune, on the Doller, a feeder of the Ill; St. Amarin, pop. 1662 for the town, or 1995 for the whole commune; Thann, pop. 3802 for the town, or 3937 for the whole commune; and Cernay, pop. 3407 for the town, or 3416 for the whole commune, on the Thann, another feeder of the Ill. At Giromagny cottons are manufactured, and a monthly fair is held for corn and cattle. At Delle tiles are made, and there are a fulling-mill and a mill for grinding bark; and at Dannemarie there are tanyards and dye-houses. Massevaux, sometimes called Masmünster, has manufactures of cotton yarn and cotton goods, copper-works and iron-furnaces: there are six yearly fairs. There are cotton-manufactories and iron-furnaces at St. Amarin, a town very pleasantly situated: there are two fairs, where hardwares, woven goods, and cattle are sold. Thann has a fine old Gothic church, dedicated to St. Théobald, remarkable for its spire, which is an imitation of that of Strasburg: the ruins of the castle of Enguelbert, near the town, are also deserving of notice. Cotton-yarn and cotton goods, including printed calicos, are manufactured; also machinery, starch, gunpowder, salt, and chemical productions. The town had its origin in the twelfth century, and in the middle ages enjoyed many privileges: it was taken by the Swedes in the Thirty Years' War. Gobel, the archbishop of Paris, who renounced the belief of a God, in the height of the revolutionary frenzy, and perished on the scaffold, was a native of Thann. At Cernay cotton-yarn is spun; calicos, cotton prints, and woollen cloths woven; an iron goods, machinery, and paper are made: there are bleach-grounds for linen. At Morvillard, a village near Delle, are some important wire-works; at Niederbrun are copper and brass works; and at Wesserling, near Cernay, cotton mills and a factory for cotton prints.

[ALSACE; RHIN, BAS.]

RHINE. This river is, in respect of length, ... fourth of European rivers, being inferior to the V... Danube, and Dnieper; but if it be viewed as a chann... commerce, it is certainly the first river of contin... Europe. It rises in the Alps of Switzerland, in s... parts of its course separates that country from Germ... afterwards divides Germany from France, traverses the ... ritories of several princes belonging to the German C... deration, and lastly it drains the plains of Holland, wh... reaches the sea by several arms. That portion of the ... which lies within or along the boundary-line of Swi... land is called the Upper Rhine; from Basel to K... Cologne, it is denominated the Middle Rhine; a... remainder of the course, to its several mouths, the L... Rhine.

Upper Rhine.—The river originates in three branch... that elevated chain of the Alps which runs eastward ... the mountain-road of St. Gothard through Graubün... or the country of the Grisons. The most eastern of ... three branches, called by German geographers the V...

Rhein (Fore Rhine) is considered the principal. It rises in two small lakes, situated on the eastern declivity of Mount Badus, belonging to the St. Gothard's group, about 7550 feet above the sea-level. These lakes are called the Lake of Toma and Lake of Sera. It runs in a ravine like a torrent, and about twelve miles from its source, at Disentis, where it is met by the second branch, the Mittel (Middle) Rhein, it is hardly more than 3050 feet above the sea. It continues its course for about 37 miles more in an east by north direction, to Reichenau and Chur. At Reichenau the waters are increased by the third branch, called the Hinter (Hinder) Rhein, and at Chur it is nearly 150 feet wide, its waters having been increased by numerous small tributaries. From Chur downwards it is navigated by small flat river-boats, and it begins to run through a valley from one to two miles wide, in a nearly northern direction towards the Boden See, or Lake of Constance. This valley is nearly 50 miles long. About 20 miles north of Chur two mountain-masses close up to the banks of the river, so as not to leave even space for a road. The eastern is called the Flaeschenberg, and the western the Schollberg. Their declivities along the river are extremely steep, and there is reason to suppose that the two mountains at some remote time formed one mass, and that the course of the river was different from what it is at present. In fact a low tract of alluvial ground extends south of the Schollberg westward to the small town of Sargans in St. Gallen, and thence to the Lake of Wallenstadt. Between this lake and that of Zürich there is also a broad tract of level alluvial ground, in which the Linth Canal has been made. As the ground between the present course of the Rhine and the Lake of Wallenstadt is little more than 20 feet above the level of the river, it is supposed that the Rhine formerly took its course through this low ground, and passing through the lakes of Wallenstadt and Zürich, followed the course of the Limmat River, which joins the Aar opposite the village of Ram. When the Rhine is unusually swollen there is some danger of its returning to this its supposed ancient bed. In 1817 and 1821 the danger was only averted by the great efforts of the inhabitants of the adjacent places. North of the narrow passage between the Schollberg and Flaeschenberg the valley is much wider, and here the river constitutes the boundary-line between the Austrian monarchy and Switzerland. Where the river enters the Boden See it runs through a swampy tract of small extent. [Constance, Lake of.] The river issues from the lake at Constanz, which is 1254 feet above the sea-level, and flowing in a western direction for a few miles, enters the Unter See (Lower Lake), which is about thirty feet lower than the Boden See. In this tract, and as far as Schaffhausen, the Rhine is navigable for large boats, but below the last-mentioned place its waters rush over a rock, which is between 55 and 70 feet high, and this waterfall is called the cataract of Schaffhausen or Laufen. The last name is derived from that of a castle which is contiguous to the waterfall. At Schaffhausen the surface of the Rhine is 1260 feet above the sea-level. Below this cataract the course of the river is very tortuous, between mountains and high hills, but its general direction is towards the west. Nearly fifty miles below Schaffhausen the navigation is again interrupted by a cataract, at the town of Laufenburg, where the bed is narrowed by projecting rocks to about fifty feet. At this point goods must be unshipped, and the barges descend the river by means of ropes. The last and least impediment to navigation in the Upper Rhine occurs near Rheinfelden, about ten miles below Laufenburg, where a rapid of some length occurs, which does not stop the navigation, but is fatal to many boats which navigate this part of the river. It is called the Höllenhaken (Hook of Hell). Below this rapid the river is only 830 feet above the sea; and at Basel only 820 feet.

Numerous tributaries join the Rhine in its upper course above Basel, but none of them are navigable or otherwise remarkable, with the exception of the Aar. This river drains the greater part of Switzerland, and is at least equal to the Rhine in the volume of water which it brings down. The Aar originates in the enormous masses which lie west of the mountain-road of the St. Gothard, and, from being always covered with snow and glaciers, are comprehended under the general name of Aar-Gletscher, or Aar-Glaciers. The upper part is in a narrow valley between very high mountains, in a general north-west direction, and in these parts it forms a cataract about 120 feet high, which is called the Aarfall, or Fall of the Aar, near the hamlet of Handeck. After a course of about 22 miles, the Aar falls into the lake of Brienz, which is about nine miles long, and somewhat more than a mile wide, very deep, and 1900 feet above the sea-level. After issuing from that lake, the Aar runs hardly three miles before it enters the lake of Thun, which is nearly twelve miles long, and on an average about three miles wide; it is 1875 feet above the sea-level. Issuing from the north-western extremity of the lake, the Aar flows first in a north-west, then in a west, and lastly in a northern direction, traversing the elevated and hilly plain of Bern nearly in the middle. Above the town of Bern it is not much navigated on account of the rapidity of its course, but a considerable quantity of wood is floated down. Below Bern it is navigated by river barges of moderate size. At Aarberg the river approaches the foot of the Jura Mountains, along the base of which it flows in a north-eastern direction as far as Aarau, north of which it enters the mountain-region which separates the plain of Bern from the valley of the Rhine, and in its tortuous course through this hilly tract the waters of the Reuss and of the Limmat join it, before it falls into the Rhine at Coblenz, a short distance above Waldshut. The whole course of the Aar exceeds 160 miles. The Reuss and the Limmat fall into the Aar near 47° 30′ N. lat., and hardly one mile from one another. The Reuss originates between the sources of the Aar and those of the Rhine, in the mountains which lie on both sides of the road that traverses the St. Gothard and its upper course, which is nearly due north, is frequently broken by rapids and cataracts, among which those of Hospital, Andermatt, and Amsteg are admired for their beauty. At the village of Klus it leaves the narrow valley, and three miles farther north it falls into the Lake of Luzern, or the Vierwaldstädter See, so much admired for the picturesque beauty of the country which bounds its shores. The form of this lake is extremely irregular: it is 1434 feet above the sea-level. Issuing from the north-western extremity of the lake, the Reuss flows generally in a northern direction, and chiefly through a hilly country, about forty miles to its confluence with the Aar near Brugg. The other great tributary of the Aar brings to it the waters of the lakes of Wallenstadt and Zürich. The former lake is about nine miles long, and more than a mile across, generally from 60 to 90 fathoms deep, and 1422 feet above the sea-level. It is united to the Lake of Zürich by the Linth and a canal. The Lake of Zürich has the form of an arch, and is about twenty-five miles long and two miles wide. It is 1310 feet above the sea. Issuing from the north-western extremity of the lake, the Limmat flows for about twenty miles through a hilly country, in a west by north direction, and falls into the Aar opposite the village of Ram. Both the Reuss and the Limmat are navigable, but on account of the rapidity of their current they are ascended only by empty barges. The Linth and its canal are also navigated.

Middle Rhine.—At Basel, where this division of the river begins, it has entirely left the mountain-region of the Alps and Jura Mountains, and at the same time it changes its western into a north-north-eastern and northern course. It flows in a valley from forty to fifty miles wide, extending between the Black Forest (Schwarzwald) and the mountains connected with it on the east, on the one side, and the Vosges and their northern prolongation the Hardt Mountains on the west, from Basel to Mainz, a distance of nearly 200 miles. At Mainz the surface of the river is only 274 feet above the sea; the fall between Basel and Mainz is therefore 536 feet, or more than 2½ feet per mile. At Kehl, in the parallel of Strasburg, the surface of the river is 443 feet above the sea. The distance of Strasburg from Basel is about eighty miles, in which space the river descends 387 feet, or 4½ feet per mile. In addition to the great rapidity of the current, the wide bed of the river contains numerous sand-banks and small islands, which are subject to sudden and frequent changes in their form and position. Navigation in this part of the Rhine is accordingly limited. The river barges employed are only from 20 to 24 tons burden, and can only take in a third of that weight in ascending the river, when they must be drawn up. Small steamboats ascend as far as Basel. Between Kehl and Mainz, a distance of more than 120 miles, the fall of the Rhine does not exceed 179 feet, or about 1½ feet per mile. Between Kehl and Germersheim, which places are about fifty miles distant from one another, the islands do not decrease in number, but they increase in size, and are less subject to change. The islands occur north of Germersheim, and the river flows slowly, making large bends. The largest kind of barges used between Strasburg and Mainz are of 100 tons burden, but in ascending they must be drawn up, which is chiefly done by horses.

Between Mainz and Bonn the Rhine runs between two mountain-regions in a narrow valley. This valley, which contains some of the most picturesque scenery on the continent of Europe, is in some parts so narrow, that there is hardly level space enough for a road between the mountains and the banks of the river. The hills along the banks of the stream contain extensive vineyards, the produce of which is known all over Europe under the name of Rhenish wines. The direction of the river from Mainz to Bingen is westward, but below Bingen it runs to the west of north. Within this part there are some dangerous places. At Bingin a ledge of rocks crosses the river, and though the Prussian government has lately somewhat lessened the danger by blasting some of the rocks, yet the impediment is not quite removed, and neither barges nor steam-boats can pass by night or in foggy weather. Near Bacharach, farther down, there is a group of rocks, and opposite St. Goar another ledge, which however is much less dangerous than that near Bingen. Between Mainz and Köln, a distance somewhat exceeding a hundred miles, the river descends 164 feet, or little more than 1½ feet per mile: at Köln it is only 110 feet above the sea-level. Numerous barges navigate within these limits, and the largest of them vary between 120 and 150 tons. The ascent is very tedious, and requires much time.

Numerous tributaries join the Rhine in its middle course. Those which flow into it from the west have a short course, and are not navigable, with the exception of the Moselle, which rises on the western slopes of the Vosges, and runs first north-west, and then north, but the greater part of its course is to the north-east. After a course of 280 miles, it joins the Rhine at Coblenz. It is navigable as far as its confluence with the Meurthe, about 160 miles from its mouth. The upper part of its course lies between hills, the middle part through the plain of Lorraine, and the lower part in a deep valley of moderate width. The slopes of the hills and mountains enclosing this valley are covered with extensive vineyards, which produce the Moselle wine. The largest of its tributaries, the Saar or Sarre, which joins it above Trier, is navigable for large river barges as far as Saarebrück, a distance of about 45 miles from its mouth, and 10 miles more for small barges.

The number of navigable rivers which join the Rhine in its middle course from the right is much greater. The most southern is the Neckar, which rises near 48° N. lat., in the mountainous tracts by which the range called the Rauhe Alp is connected with the Black Forest. Its course for more than 30 miles is northward, and afterwards north-east along the base of the Rauhe Alp for about the same distance. Ten miles above Stuttgard it turns north-west, but below that town its general course is north for about 80 miles, when it turns to the west, and after flowing in that direction 30 miles, falls into the Rhine at Mannheim. The whole course of the Neckar is above 180 miles, and, with the exception of the first 30 miles, lies through a country swelling continually into gentle hills of moderate elevation, which are carefully cultivated, and produce excellent wine. It begins to be navigable at Kannstadt, near Stuttgard, for small barges; but below Heilbronn it is navigated by barges of 20 tons. One of its tributaries, the Enz, which falls into it from the left, is navigable to Vahingen, about 10 miles upwards.

The most important of the affluents of the Rhine is the Main or Mayn, which falls into it opposite Mainz. Its sources are in the Fichtelgebirge, not far from the boundary of Bohemia, where it originates in two branches, of which the northern is called the White and the southern the Red Main. The two branches unite about two miles and a half below Kulmbach, and begin to change their western course into a southern. Not far from Bamberg the river is joined by the Rednitze: it then flows west by north to Schweinfurt, whence it again runs south to Markbreit, and from that place to the north-north-west to Gemünden. From Gemünden it again flows southward, and making a wide sweep, encircles the mountain-region of the Spessart. At Hanau it turns westward, and passing near Frankfort in that direction, joins the Rhine. Though its sources are only about 150 miles from its mouth, the whole course exceeds 360 miles, owing to the numerous large bends. This circumstance renders it one of the m[ost] navigable rivers on the Continent. River barges as[cend] above the mouth of the Rednitz, more than 250 miles [from] its mouth; and from Kitzingen downwards, it is naviga[ble] by vessels of 100 tons burden. The whole course [is] through a hilly but rather fertile and well-cult[ivated] country. The Rednitz is the only affluent of the M[ain] which is navigable. The navigation of the larger [river] barges, from 25 to 30 tons burden, ceases at Forch[heim]. As no high hills intervene in those parts between the M[ain] and the Danube, a canal, which originally was project[ed by] Charlemagne, is now in progress, which is to extend [from] Forchheim along the banks of the Rednitz and those of Altmühl to the Danube. This canal will establish a w[ater] communication between the North Sea and the B[lack] Sea.

Farther north the Rhine is joined by the Lahn, w[hich] falls into it a little above the mouth of the Moselle at N[ie]derlahnstein: it flows about 140 miles, and is navigab[le for] moderate-sized river boats to Diez, about 20 miles fr[om its] mouth, and for smaller boats to Wetzlar, about 70 [miles] from its confluence with the Rhine. It traverses a [very] hilly country. The river Sieg, which falls into the R[hine] below Bonn, flows about 70 miles, and is navigable to S[ieg]burg, which is about eight miles from its mouth.

Lower Rhine.—From Köln to its mouths, a distance [of] about 300 miles, the course of the Rhine is through a [low] level country, though the western declivity of the h[ills of] the Sauerland are near its eastern bank, between Köln [and] Düsseldorf. The current is extremely gentle, as the [whole] fall does not amount to much more than four inches [per] mile, the surface at Köln being, as already observed, 110 feet above the sea-level. From this town downwar[ds] the Rhine may be navigated by sea-vessels from 300 to [...] tons burden; and a few years ago, a vessel cleared out f[rom] Köln for New York. But flat river barges are ge[ne]rally used, on account of the numerous sand-banks w[hich] narrow the navigable channel.

About 200 miles from its mouth, and soon after it [has] entered Holland, the Rhine begins to divide into sev[eral] arms; but before this division, the waters are increas[ed by] three navigable rivers, by the Erft from the left, and by [the] Ruhr and Lippe from the right. The Erft, which fall[s into] the Rhine above Düsseldorf, flows about 60 miles, bu[t is] only navigable a few miles above its junction with the Ri[ne]. The Ruhr, whose course is generally to the west for a[bout] 100 miles, is navigable for boats about one-half of its co[urse] to Langschede above Schwerdt. Its course being r[apid], it has been made navigable by the construction of six [...] locks; it is generally navigated by coal-barges, as [the] adjacent country contains the richest coal-measures [of] Northern Germany. The number of these barges is s[aid] to amount to 3000. The Ruhr falls into the Rhine [at] Ruhrort. The Lippe, which joins the Rhine near W[esel], is somewhat more than 100 miles long, and is naviga[ble] from Lippstadt by small river-boats, and from Lunen [by] large ones.

Near the village of Pannerden, which is within t[he] territories of Holland, the Rhine divides into two a[rms], of which the southern is called the Waal, and t[he] northern preserves the name of Rhine. Nearly two-th[irds] of the volume of water run into the Waal, which is [more] than 210 yards wide, while the Rhine is only 114 y[ards] wide. The Waal runs westward, and the Rhine m[ore] north-west. The Rhine divides again about 12 miles l[ower] down, above Arnheim, into the Yssel, which runs to [the] north, and the Rhine, which runs off to the west. T[he] Yssel was originally a canal, cut by Drusus, to unite t[he] Rhine with the river which now is called Oulde (Old) Y[ssel]. It falls into the Zuider Zee. The Rhine running westwa[rd] divides for the third time about 30 miles lower down [at] Wyck by Duurstede. The southern arm is called t[he] Leck, and the northern goes by the name of Kromme R[hine] (Crooked Rhine): the Leck is the larger river. The Cro[oked] Rhine runs north-west to Utrecht, where it divides fo[r the] fourth and last time. The arm which runs northward [is] called the Vecht, and falls into the Zuider Zee; the ot[her], whose name is changed into that of Oulde Ryn (Old Rh[ine]), continues westward through the marshes of Holland, w[here] the waters are used for feeding numerous small canals. [It] passes through Leyden, and formerly did not reach the [sea], being prevented by some sandy dunes which line the sh[ores] of this part of Holland; but in 1807 a canal was m[ade] through them, and the river now discharges a small quantity of water into the sea at Katwyck, north-west of Leyden.

The Leck, or middle branch of the Rhine, was originally also a canal, made by the Roman general Corbulo; and it existed as such to A.D. 839, when the bed was greatly enlarged by an inundation, and thus it became the principal river, and the true Rhine was reduced to insignificance. It runs from Wyck by Duurstede westward for about 50 miles, when it is joined from the south by a branch of the Maas or Meuse, called the Merwe or Merwede. On approaching the sea, another arm of the Maas, called the Oulde Maas (Old Maas), joins it, and hence to its mouth the wide æstuary of the river is called the Maas.

The Maas or Meuse rises near 48° N. lat., in the French department of Haute Marne, in that ridge of high land which unites the chain of Côte d'Or with the Vosges, and is called Monts de Faucille. Its general direction through France to Sedan is to the west of north; then for a few miles west, and again north, until it reaches Namur, whence it flows first to the north of east to Lüttich or Liege, and thence to the east of north to Venlo and Broekhuizen. From the last-mentioned place it declines to the north-west, and, before it reaches Grave, to the west, in which direction it flows nearly parallel to the Waal for more than 80 miles, approaching that river in one place within two miles. Both rivers unite at Gorkum, and the name of the Waal is merged in that of the Maas. The course of the Maas to its confluence with the Waal is about 460 miles. The Waal runs about 80 miles from the Pannerden to Gorkum. After its junction with the Waal, the Maas likewise divides. The first division occurs a few miles west of Gorkum, near the village of Hardingsvelt. One arm runs southward, under the name of West Kil; and the other, the Merwe or Merwede, to the west. The Merwede afterwards divides again into the proper Merwede and the Oulde Maas, both of which unite with the Leck, as already observed. The West Kil forms the Bies Bosch, a kind of lake, literally strewed with small islands covered with low trees; turning westward it is called Hollands Diep. This Hollands Diep, which is about two miles wide, divides also into two arms, of which the northern, called the Haring Vliet, is about two miles wide; but towards its mouth it widens to three miles, and is called Rivier Flakkee, or Shallow River. The southern arm is known by the names of Volke Rak and Krammer in different places, and is more than a mile across, but full of shoals. Between the two arms of the Hollands Diep is the island of Over Flakkee. An arm of the Krammer runs into the Ooster Schelde. Thus the Rhine reaches the sea by four mouths, the Oulde Rhine, the Maas, the Rivier Flakkee, and the Krammer. The whole country between the arms of the Rhine, after its division at Sterneschanze, is intersected by numerous canals, most of which serve for the purpose of internal navigation, though only for small boats.

The whole course of the Rhine amounts to about 950 miles, of which about 350 are included in the middle course, the upper and lower course not exceeding 300 miles.

The delta of the Rhine is bounded on the east by the Yssel, on the south by the Waal and Maas, and on the other sides by the North Sea and the Zuider Zee: it comprehends the whole of the three Dutch provinces of North and South Holland and Utrecht, and nearly two-thirds of Guelderland. Within these limits it occupies about 4150 square miles; but the whole of this surface is not level or alluvial ground, for nearly the western half of Utrecht, and that part of Guelderland which is between the Rhine, the Yssel, and the Zuider Zee, is slightly hilly, and the soil is not alluvial. When this hilly tract, which occupies about 1128 square miles, is subtracted, the alluvial portion of the delta does not exceed 3030 square miles. To this however must be added the extensive alluvial tracts which line the Yssel, the Waal, and the Maas beyond the limits of the delta as here defined, and occupy about 1000 square miles. If the greater part of the province of Zeeland, which is contiguous to these lowlands (about 500 square miles), and the low tracts on both sides of the Rhine above its division, from Wesel downwards (250 square miles), are added, the whole extent of the low country near the mouths of the Rhine is 4780 square miles. All this country would occasionally be covered with the inundations of the river, or by the sea, if it were not protected by embankments. The river embankments begin at Wesel, in the Prussian province of Düsseldorf, and extend on both sides of the different arms of the Rhine to the sea. These embankments are generally from 25 to 30 feet above the lowest level of the river. In the basin of the Rhine the winter usually lasts from six weeks to two months, during which time the river is covered with ice, and the snow accumulates in the adjacent countries. If the snow has fallen in greater quantities than usual, and is suddenly dissolved by warm rains, the river in a short time swells to an extraordinary height, and lays the contiguous low lands under water. No part of these low lands is more subject to such inundations than the Betuwe, or that tract which extends between the Rhine and Leck on the north and the Waal on the south. When such inundations take place, they are always attended with great loss of property, and sometimes of life, as was the case in the great inundation of 1799. In that year the masses of ice stopped the current, and the water, rising to the level of the embankments, poured over them like a cataract into the adjacent low lands. According to a rough estimate, about one thousand square miles were thus laid under water.

The basin of the Rhine, according to a tolerably accurate calculation, covers a surface of 79,482 square miles, or about 7000 square miles less than the area of Great Britain. The *Upper basin* of the river resembles a triangle, whose base extends, near 46° 30′ N. lat., over 4 degrees of longitude (from 6° to 10° E. long.), and consequently is 180 miles in length. Betweeen 10° and 7° it is formed by the highest ranges of the Alps, and between 7° and 6° by the Jorat mountains and the Jura. The eastern border of the Upper basin extends along 10° E. long. from 46° 30′ to 48°, and is somewhat more than 100 miles long. It is mostly formed by high ranges, which are offsets of the Alps. The third line of the triangle is not a straight line. It begins on the south, near the place where 6° E. long. is cut by 46° 30′ N. lat., and extends along the Jura mountains to Basel and the Schwarzwald in a north-eastern direction, until in approaching 48° N. lat. it turns east and runs in that direction to 10° E. long. This portion of the basin contains 12,820 square miles: viz., of Switzerland, 10,300; of Austria, 860; of Wirtemberg, 360; of Baden, 1300: total, 12,820; and the whole of it, with the exception of a comparatively small tract, is from 1300 to 1400 feet above the sea-level; many parts indeed rise much higher, especially those which are enclosed by the ranges of the Alps.

The *Middle* basin of the Rhine lies between 48° and 51° N. lat. On the west side of the river, its margin extends from the northern part of the Jura mountains westward across the southern parts of the Vosges mountains to the Monts de Faucille, or those heights in which the Seine, Maas, Moselle, and Saône originate. It then continues northward along the ridge of hills which separate the valleys of the rivers Maas and Moselle to the Ardennes, and afterwards north-east over the mountain-region of the Eifel to Bonn. This portion of the Middle basin occupies 18,355 square miles, of which there are

	Sq. M.
In France (departments of Haut Rhin, Bas Rhin, Moselle, Meurthe, and about half of the Vosges)	9,731
In Bavaria (Rheinkreiss)	2,213
In Oldenburg (Birkenfeld)	195
In Prussia (Coblenz, Trier)	4,806
In Luxemburg	1,410
	18,355

On the east side of the river, the outer edge of the Rhine begins near the source of the Danube, whence it extends along the ridge of the Rauhe Alp east by north, until it reaches the place where 10° 30′ E. long. is cut by 49° N. lat. Thence it extends north-east over the hilly plain of Franconia, where several tributaries of the Danube and Rhine interlock, to the Fichtelgebirge (50° N. lat.). In this parallel the basin of the Rhine has attained its greatest width, extending from the source of the Sambre (3° 40′ E. lat.) to that of the Main (11° 40′), about 320 miles. From the Fichtelgebirge the outer border of the basin runs along the Frankenwald and Thüringerwald west-north-west to the sources of the Werra, and thence westward over the Rhön mountains, the Vogelsberg, and Westerwald to the mouth of the Sieg, where it terminates at the Siebengebirge opposite Bonn. The eastern portion of the Middle basin contains 21468 square miles, viz.:—

Of Wirtemberg	5,320
Of Baden	4,644
Of Bavaria	6,944

Of Darmstadt . . .	2,387
Hesse-Homburg . . .	172
Nassau	1,801
Of Prussia (Coblenz) . .	200
	21,468

Thus the whole of the Middle basin has an area of 39,823 square miles.

The Lower basin of the Rhine lies between 50° 40′ and 52° 40′ N. lat., except a long narrow tract which comprehends the Upper basin of its confluent the Maas, and which extends southwards along the western edge of the Middle basin to 48° N. lat., or to the Monts de Faucille. This valley is separated from the basin of the Seine by the Forêt des Argonnes. At this place the basin of the Maas begins to border on that of the Schelde. The watershed between these two rivers extends south-west and north-east, and is formed by a hilly country of moderate elevation, which terminates in the neighbourhood of Maastricht. From this place the watershed between the two rivers extends north-west and west, and is formed by a broad tract of elevated ground covered with moors and heaths. The left portion of the Lower basin contains an area of 15,495 square miles, of which there belong

To France (in the departments of Meuse, Vosges, Ardennes, and Du Nord)	4,551
„ Luxemburg	1,301
„ Prussia (Aachen, Köln, and Düsseldorf) .	3,581
„ Belgium (Liege, Limburg, Namur, Hennegau)	4,065
„ the Netherlands (North Brabant) . .	1,996
	15,495

On the right side of the Rhine, the outer edge of the Lower basin extends from the source of the river Sieg, which is in the Westerwald, north-eastward to the ridge called the Osning. Thence it runs along the northern side of the valley of the Lippe westward over an elevated tract covered with heath. The remainder of the border of this part of the basin is in the moorlands which are drained by the Reege, a confluent of the Vecht, and it terminates in the alluvial tracts which extend northward from Zwoll on the Yssel. The area of the right portion of the Lower basin of the Rhine, including the islands which lie between its arms, amounts to 11,344 square miles, comprehending

Of Prussia (Minden, Münster, Arensberg, Köln, Düsseldorf)	6,725
Of the Netherlands (Guelderland, Utrecht, and Holland)	4,619
	11,344

The whole of the Lower basin of the Rhine covers 26,839 square miles.

Though the basin of the Rhine extends from 46° 30′ to 52° N. lat., nearly the whole of it has the same climate. The distance between the Upper and Lower basin, amounting to about five degrees, is compensated by the greater elevation of the Upper basin. Thus the plains of Switzerland, which are about 1400 feet high, resemble in climate the low countries which lie between 51° and 52° N. lat. The countries in the middle basin, being less elevated in proportion, enjoy a somewhat milder climate than the plains of Switzerland and the low lands near the mouth of the Rhine.

RHINE, ANTIENT (*Rhenus*, Ῥῆνος.) The Romans first became acquainted with the Rhine by the conquests of Julius Cæsar in Gaul, who crossed it twice to punish the Germans. (Cæs., *Bell. Gall.*, iv. 16, 17; vi. 9.) He knew however nothing of the northern or southern part of the river except from report, and appears himself never to have gone farther north than the Scaldis (Schelde), though his cavalry on one occasion reached the country where the Rhine and the Mosa meet. (*Id.*, vi. 33; iv. 15.) According to his account, the Rhine rises in the country of the Lepontii, who inhabit the Alps, and flows rapidly a long distance through the territories of the Nantuates, Helvetii, Sequani, Mediomatrici, Triboci, and Treviri; and when it approaches the ocean it divides itself into many branches, and after forming several great islands, flows into the ocean by many mouths. (*Id.*, iv. 10.)

The campaigns of Drusus and Tiberius in Rhætia and the north-western parts of Germany gave the Romans a more accurate knowledge of the course of this river. According to Strabo, it rises in Mount Adula (St. Gothard), which is part of the Alpes Rhæticæ, and at no great distance from the sources of the Rhône. Thence it flows northwards, and forms marshes and a great lake, by which Strabo must mean the Lacus Brigantinus (Boden See, or Lake of Constance); it afterwards becomes a river again, and flows parallel to the Sequana. It falls into the sea opposite Cantium (Kent), which could be seen from the mouths of the Rhine. Asinius said that the river was 6000 stadia in length, but Strabo thought that it would not be more than half that length if it flowed in a straight line; and that on account of its rapidity not more than 1000 stadia ought to be allowed for windings in its course. (Strab., iv., p. 1[illegible], 193, 204; ii., p. 128; i., p. 63.) Tacitus also states (*Germ.*, c. 1) that the Rhine rises in the Rhætian Alps.

Antient writers differ respecting the number of mouths by which the Rhine falls into the ocean. Cæsar, as already stated, says that there are several, but most other writers speak only of two or three. Virgil (*Æn.*, viii. 727), Asinius (Strab., iv., p. 193), and Tacitus (*Ann.*, ii. 6) speak only of two; of which, according to Tacitus, the western is called Vahalis till its union with the Mosa, when it takes the name of the latter river, while the eastern, which forms the boundary between Gaul and Germany, preserves the name of Rhine. Pliny (*Hist. Nat.*, iv. 29), Ptolemæus (ii. 9), and other writers say that the Rhine falls into the sea by three mouths, of which the eastern, according to Pliny, was called Flevum, and the western, formed by the union with the Mosa, Helium; while the middle one, which was only a stream of moderate size, retained the name of Rhine. The channel called Flevum is supposed to have been formed by the canal which Drusus dug to connect the Rhine with the Isala, and by means of which he and Germanicus sailed to the ocean. (Suet., *Claud.*, c. i.; Tac., *Ann.*, ii. 8.) The Isala, increased by the waters of the Rhine, flowed northwards into a great lake called Flevo, on issuing from which it became a river again, and fell into the ocean after forming an island of the same name. (Mela, iii. 2.) In course of time the sea made great inroads upon the land round the mouth of this river, till at length it submerged that part of the country, and became united with the lake Flevo, thus forming the modern Zuider Zee.

(Ukert, *Geographie der Griechen und Römer*, vol. [illegible] part. ii., p. 147, &c.)

RHINE, circles of the Upper, Middle, and Lower Rhine in the grand-duchy of Baden. [BADEN.]

RHINE, THE CIRCLE OF THE, in the kingdom of Bavaria (now the PALATINATE), is entirely detached from the rest of the kingdom, and lies on the left bank of the Rhine. It is composed of the greater part of the French department of Mont Tonnerre and small portions of those of the Lower Rhine and the Saar, which were taken from France in 1814, and assigned by the Congress of Vienna to Austria, which made the country over to Bavaria. It is bounded on the north-west by Rhenish Prussia, on the north by Rhenish Hesse, on the east by Baden, from which it is separated by the Rhine, and on the south by France, Rhenish Prussia, Coburg, and Hesse Homburg; the area within these limits, according to the 'Military Topographical Atlas' (as Hassel, 1819, states), is 140 German or 2940 English square miles. But Schlieben (1831), Hörschelmann (1834), and Cannabich (1836), all agree in making it 1[illegible] German or 2100 English square miles. The 'Weimar Almanach' of 1840 follows Hassel. The circle is very mountainous, being traversed by branches of the Wasgau (the Vosges); but there are some beautiful valleys and plains, and the country is very fertile and well cultivated. The mountains are for the most part covered with forests; very few are quite bare, the south sides, at least, being everywhere covered with vines. The principal river is the Rhine. All the other streams are tributaries to the Rhine; the chief of these are the Lauter, which forms the boundary towards France; the Queich, the Speyerbach, and the Nahe. Agriculture is carried to a high degree of perfection, and the products are corn of all kinds, pulse, flax, hemp, tobacco, madder, and hops. Fruit is very extensively cultivated, and the inhabitants derive very large profits from the walnuts and chestnuts. The best wines are produced on the Rhine; [illegible] sorts are in good repute; the greater part is consumed in the country. Though agriculture is the chief occupation of the inhabitants, there are flourishing manufactures of woollen, cotton, and hardware. The population is 565,345, of which the majority are Roman Catholics; the remainder are Protestants. [DEUX PONTS; LANDAU; SPEYER.]

RHINELLA, Fitzinger's name for a genus of Frogs, *Oxyrhynchus* of Spix. [Frogs, vol. x., pp. 494-496.]

RHINO'CEROS (the Greek *ῥινόκερως*), the name of a genus of pachydermatous quadrupeds, placed by Linnæus in his order *Bruta*; and by Illiger in his order *Multungula*, family *Nasicornia*. It has been a question whether one of the species, *Rhinoceros unicornis*, Linn. (*Rhinoceros Indicus*, Cuv. and Desm.) is not the ראם (*Reem*) or רים (*Reim*) of Scripture (*Numb.*, xxiii. 22, xxiv. 8; *Deut.*, xxxiii. 17; *Job*, xxxix. 9, 10; *Psalms*, xxii. 21; xxix. 6; xcii. 10; *Isaiah*, xxxiv. 7).

In the Septuagint the word is translated *μονόκερως* (*Monoceros*, or *Unicorn*), except in Isaiah, where it is rendered *ἁδροὶ* (*Hadroi*, or *the mighty or powerful ones*).

In the Tigurine and Vulgate versions the word is rendered (*Numb.*, xxiii. 22; *Job*, xxxix. 9, 13) *Rhinoceros*, with a note to the former, that others read *Monoceros*; and in Scheuchzer's *Physica Sacra* we have (tab. 313) *Numb.*, xxiii. 22, illustrated by a somewhat extravagant and exaggerated figure of a one-horned Rhinoceros with '*Reem*: *Rhinoceros*' below the plate.

In the Bible 'Imprinted at London by Robert Barker, Printer to the King's most excellent Maiestie' ('Breeches' Bible) the word used is 'Unicorne,' and 'Unicorn' is the expression in the version now in use in our churches.

Some are of opinion that the *Reem* or *Reim* of Scripture were savage animals of the Bovine genus, and others that the word signified the *Oryx*, observing that *Reem* is the Arabian name for a species of wild goat or gazelle. These allege that the *Reem* was two-horned (*Deut.*, xxxiii. 17; *Psalms*, xxii. 21.) The better opinion seems to be that the animal or animals intended to be designated in most of the passages quoted, if not in all, was or were the *Rhinoceros Unicornis*, or *Great Asiatic one-horned Rhinoceros*. M. Lesson expresses a decided opinion to this effect; and indeed the description in *Job* (chap. xxxix.) would almost forbid the conclusion that any animal was in the writer's mind except one of surpassing bulk and indomitable strength.

The impotence of man is finely contrasted with the might of the Rhinoceros in this description, which would be overcharged if applied to the less powerful animals above alluded to.

It has also been doubted whether accounts of the Indian *ὄνοι ἄγριοι* (Wild Asses) given by Ctesias (*Indic.*, ed. Bähr) were not highly coloured and exaggerated descriptions of animals of this genus, and whether the *ὄνος Ἰνδικὸς* (Indian Ass) of Aristotle was not a Rhinoceros.

The account of Ctesias is evidently tinged with fable; but there are parts of it which suit well with the habits of a Rhinoceros. He describes his *Wild Asses* as being as large as horses, and larger, with white bodies, red heads (*πορφυροῦν*), and blue eyes (*κυάνεον*), having a horn on the forehead a cubit long, which for the extent of two palms (*παλαιστάς*) from the forehead is entirely white; above it is pointed and red (*φοινικοῦν ἐρυθρὸν σφόδρα*), and black in the middle. Of this horn drinking cups are formed, and those who use them are said not to be subject to spasm (*σπασμὸς*) nor epilepsy (*ἱερὰ νόσος*), nor to the effects of poison, provided, either before or after taking the poison, they drink out of them wine or water or any other liquid. Other asses, whether wild or domesticated, have no astragalus, neither have the other wild solipedes (*μώνυχα*); but these have an astragalus and a gall bladder (*χολὴν ἐπὶ τῷ ἥπατι*). 'Their astragalus,' adds Ctesias, 'which I have seen, is very beautifully formed (*κάλλιστον*), in figure and size like that of an ox, heavy as lead, and red throughout like cinnabar. This animal is very swift and very strong. Neither a horse nor any other pursuer can overtake it. It begins its progress slowly, increasing in speed as it goes on, and runs quicker and faster. They are not naturally ferocious, but when they first lead forth their little young ones to graze, and are surrounded by many horsemen, they are unwilling to fly and leave their young, but fight with horns and heels (*λακτίζοντες*) and teeth (*δάκνοντες*), killing many horses and men. They are also destroyed by arrows and javelins, for they are not to be taken alive. The flesh is not eatable by reason of its bitterness, but the animals are hunted for the sake of the horns and astragali.'

It is not at all improbable that these parts, so much sought after on account of supposed virtues, underwent some process by which they were artificially coloured in the manner above described.

Aristotle, who (lib. viii., c. 28) speaks of Ctesias as not being worthy of credit, notices (lib. ii., c. 1) the *Ἰνδικὸς ὄνος* (Indian Ass). He observes that he has never seen a one-horned solidungulous animal; but there are a few which are monocerotous and solidungulous, such as the one-horned Indian ass (*Ἰνδικὸς ὄνος μονόκερως*), and that it is the only one of the solidungulous animals which has an astragalus.

Agatharchides describes the one-horned Rhinoceros by name, and speaks of its ripping up the belly of the Elephant. (*Phot. Bibl.*, cod.) This is probably the earliest occurrence of the name *Rhinoceros*.

The rhinoceros which figured in the celebrated pomps of Ptolemy Philadelphus was an Ethiopian, and seems to have marched last in the procession of wild animals, probably on account of its superior rarity, immediately after the camelopard, and before the men carrying Bacchus fleeing to the altar of Rhea from the persecution of Juno. (Athenæus, *Deipn.*, v., c. xxxii.)

Dion Cassius (lib. li.) speaks of the rhinoceros killed in the circus with a hippopotamus in the show given by Augustus to celebrate his victory over Cleopatra; and says that the hippopotamus and this animal were then first seen and killed at Rome. If the rhinoceros was one-horned, as it appears to have been from his description, he was certainly wrong as to the sight at least; for Pliny (*Hist. Nat.*, viii. 19), alluding to the games of Pompey the Great, remarks, 'iisdem ludis et rhinoceros unius in nare cornu, qualis sæpe visus;' and probably equally wrong as to the killing, for upon great occasions few animals left the arena alive, and Pompey was not likely to have risked his popularity by baulking the Roman appetite for blood. It is not improbable that the rhinoceros slain upon the occasion of the victory of Augustus with the hippopotamus was African, and two-horned. If so, Dion would be right; for it does not appear that a two-horned rhinoceros had ever been either seen or slain previously.

The rhinoceros so clearly described by Strabo (lib. xvi., p. 774) as seen by him, was one-horned. The folds of the skin are distinctly alluded to: that noticed by Pausanias (lib. ix., c. 21) as 'the bull of Ethiopia' was two-horned, and he describes the relative position of the horns.

Mr. Wood (*Zoography*) gives an engraving of the coin of Domitian (small Roman brass) on the reverse of which is the distinct form of a two-horned rhinoceros: 'that coin which, with the epigram of Martial, has so puzzled antiquaries, and led some of them astray, when a very little knowledge of natural history would have kept them in the right road.

'The exhibition of the two-horned Rhinoceros to the Roman people, probably of the very same animal represented on the coin,' says Mr. Wood, 'is particularly described in one of the epigrams attributed to Martial' ('De Spectaculis Libellus,' *Ep.* xxii.), 'who lived in the reigns of Titus and Domitian.'

'The following are the lines:—

> Sollicitant pavidi dum rhinocerota magistri,
> Seque diu magnæ colligit ira feræ,
> Desperabantur promissi prœlia Martis;
> Sed tamen is rediit cognitus ante furor.
> Namque gravem gemino cornu sic extulit ursum,
> Jactat ut impositas taurus in astra pilas.

'By this description it appears that a combat between a rhinoceros and a bear was intended, but that it was very difficult to irritate the more unwieldy animal, so as to make him display his usual ferocity; at length however he tossed the bear from his double horn, with as much facility as a bull tosses to the sky the bundles placed for the purpose of enraging him. Thus far the coin and the epigram perfectly agree as to the existence of the double horn; but unfortunately commentators and antiquaries would not be convinced that a rhinoceros could have more than one horn, and have at once displayed their sagacity and incredulity in their explanations on the subject. Hence we find a similar coin engraved in the second volume of Cooke's "Medallic History of Rome," where the animal is misrepresented, and particularly the horns, which appear like tusks, bending in different directions. After quoting the lines of Martial, Mr. Cooke observes, that it is the opinion of Bochart that the disputed line should be read thus:—

> *Namque gravi geminum cornu sic extulit ursum.*

By which alteration we should have two bears instead of one;* but Mr. Cooke proposes to omit only one letter, the *s* in the word *ursum*, by which means he turns the bear into a wild bull; and as it is perfectly natural that the wild bull, or urus, should have two horns, he translates the line thus:—

> * And toss a ponderous bull [illegible]

Struck with amazement, we beheld upborne
The buffal dreadful with his double horn.

If Cooke had seen the coin himself, or had consulted that book so useful to a medallist, the "Catalogue of Dr. Mead's Coins," he would not have deprived the epigram of its original and curious information.'

Two at least of these two-horned rhinoceroses were shown at Rome in the reign of Domitian.

The emperors Antoninus, Heliogabalus, and Gordian also exhibited Rhinoceroses, and Captain W. H. Smyth, R.N., noticing a coin of the emperor Philip (large brass), speaks of a noble lion on the reverse as representing one of the *Leones Mansueti* mentioned by Capitolinus. 'It seems,' says Captain Smyth, speaking of the *Sæculares Augustorum* (the legend on the reverse), 'that there were provided no fewer than 32 elephants, 10 tigers, 10 elks, 60 lions, 30 leopards, 1 hippopotamus, 1 rhinoceros, 40 wild horses, 20 wild asses, and 10 camelopards, with a vast quantity of deer, goats, antelopes, and other beasts. And still further to increase the public *hilarity*, 2000 gladiators were matched in mortal affray.' (*Descriptive Catalogue of a Cabinet of Roman Imperial large Brass Medals.*)

Cosmas speaks expressly of the Ethiopian Rhinoceros as having two horns and of its power of moving them.

The first Rhinoceros seen by modern Europeans appears to have been a *Rhinoceros unicornis*, Linn., sent from India to Emmanuel, king of Portugal, in 1513. Emmanuel sent it as a present to the pope, but the animal in an access of fury sunk the vessel on its passage. A sketch of the animal was sent from Lisbon to Nürnberg for Albert Dürer, who engraved the extravagant figure from which those of Gesner, Aldrovandi, Jonston, and Scheuchzer were taken. Among other monstrosities, the animal, which is represented as if it were clad in offensive and defensive armour, has a second small horn projecting from the top of the shoulders. A reduced copy of the same figure is given in the early edition of Petiver. In 1656 we find in the *Catalogue of the Musæum Tradescantianum* (sect. ii., '*Four-footed* Beasts, *with some Hides, Hornes, Hoofs*')—

'The Rhinoceros . $\begin{cases}\text{horn.}\\ \text{jaw-bone.}\\ \text{back-bone.'}\end{cases}$

In 1685 one was brought alive to England; another was shown throughout a great part of Europe in 1739; and a fourth, a female, in 1741. The Rhinoceros of 1739 was described and figured by Parsons (*Phil Trans.*, xlii.), and he also mentions that of 1741, which animal Cuvier believes to be the same that was shown at Paris in 1749, painted by Oudri, and afterwards engraved by Edwards (*Gleanings*), and that figured by Albinus. It was certainly that described by Daubenton, and the subject of the observations of Meckel. The Rhinoceros whose osteology is described by Cuvier was the fifth that had come to Europe. It arrived at Versailles in 1771, being then very young, and Buffon notices it in his supplement. This animal died in 1793, at the age of 25 or 26. In 1790 a Rhinoceros was brought from the East Indies to this country as a present to Mr. Dundas, who gave the animal away. It was afterwards purchased by Pidcock for 700*l.*, and was exhibited at Exeter Change and about the country. A seventh, very young, destined, it is said, for the menagerie of the emperor of Germany, arrived from the Indies in 1800, and died in London soon after its arrival: this animal was dissected by Mr. Thomas, who published his observations in the *Philosophical Transactions*. An eighth, which afterwards went to Germany, was seen at Paris not many years ago. All these were one-horned. Of late years several of the same species (*R. Indicus*) have arrived in London: one of these, a very fine healthy animal, was bought by the Zoological Society of London, and is now (January, 1841) alive in their gardens in the Regent's Park.

No two-horned Rhinoceros seems to have been brought alive to Europe in modern times. Indeed, up to a comparatively late period, this form was known only by the horns which were preserved in museums, nor did voyagers give any sufficient details to impart any clear idea of the form of the animal. The rude figûre given by Aldrovandi (to whom it was communicated by Camerarius), in his chapter *De Asinis Cornutis* (published in 1639), leaves no doubt that, wretched as it is, it must have been taken from a two-horned Rhinoceros. This is copied by Jonston (pl. xi.), who has given the animal the head of an ass or mule garnished with a couple of horns, and a flowing tail in order to make it more asinine. The collar, too, is made much more smart. These are the two earliest modern figures of a two-horned Rhinoceros known to us. Dr. Parsons endeavoured to show that the one-horned Rhinoceros always belonged to Asia, and the two-horned Rhinoceros to Africa: but, as we shall presently see, there are two-horned Rhinoceroses in Asia as well as in Africa. Flacourt, in his *History of Madagascar*, states that he saw one in the Bay of Soldagne, near the Cape of Good Hope, at a distance. Kolbe and others always considered the Rhinoceros of the Cape as two-horned: but Colonel Gordon seems to be the first who entirely described the species with any exactness, and his description was given by Allamand in the supplement of the Dutch edition of Buffon. Sparrman gave a very detailed description of the Cape Rhinoceros in the *Transactions of the Swedish Academy* (1778), and in his *Voyage*. The description, to which we shall hereafter refer, is accompanied by sufficiently accurate figures, though that of the animal is stiff and ill-designed. At this period it was well known that the Cape species was not only distinguished by having two horns from the Indian Rhinoceros then known, but also by the absence of the folds of the skin so remarkable in the latter. Camper, in his treatise on the two-horned Rhinoceros, not only confirmed Sparrman as to the point of the Rhinoceros of the Cape having 28 molar teeth, but also the statement of Dr. Parsons and Daubenton, that the Indian species has the incisors separated from the molars by a wide space.

Miller (Pennant, *Quadrup.*) had already noticed a Sumatran Rhinoceros, when Mr. W. Bell published, in the 'Philosophical Transactions' (1793), his account of a Rhinoceros of Sumatra apparently intermediate between that of the Cape and the Indian species already known; for whilst this species has two horns, and the skin but little folded, resembling in these points the Rhinoceros of the Cape, an interval intervenes between its incisors and molars, as in the Indian one-horned Rhinoceros; and it also has the small intermediate incisors below.

The observations of MM. Diard and Duvaucel confirmed the strong suspicion entertained by Cuvier, that the one-horned Rhinoceros, or *Badak* of Java, is a different species from the one-horned Indian species so long and so well known.

It now becomes necessary to notice the carelessness, to call it by the mildest name, of Bruce, who gave to the world a representation of a two-horned Rhinoceros from Abyssinia, with a strongly-folded skin. The truth appears to be, that the body of the animal figured by Bruce was copied from that of the One-horned Rhinoceros given by Buffon, to which Bruce added a second horn. Salt proves that the Abyssinian Rhinoceros is two-horned, and that it resembles that of the Cape. Mr. Burchell (1817) published a good and faithful account of a second species of African Rhinoceros, under the name of *Rhinoceros simus*; and Dr. Andrew Smith has added a third, to which he assigns the specific name of *Keitloa*.

Organization.

Skeleton.—The bony framework of the animal of this genus approximates to that of the *Hyrax*, the Tapirs, and the Horse among living genera. Though a general resemblance pervades the entire skeleton of the animals of this genus, there are certain differences, in the skull especially, which render it adviseable to notice certain of the species separately with regard to their osseous structure. All the species have seven molar teeth on each side, both in the upper and under jaw; but the species differ as to the incisors.

Rhinoceros Indicus. (*Rhin. Unicornis*, Linn.)

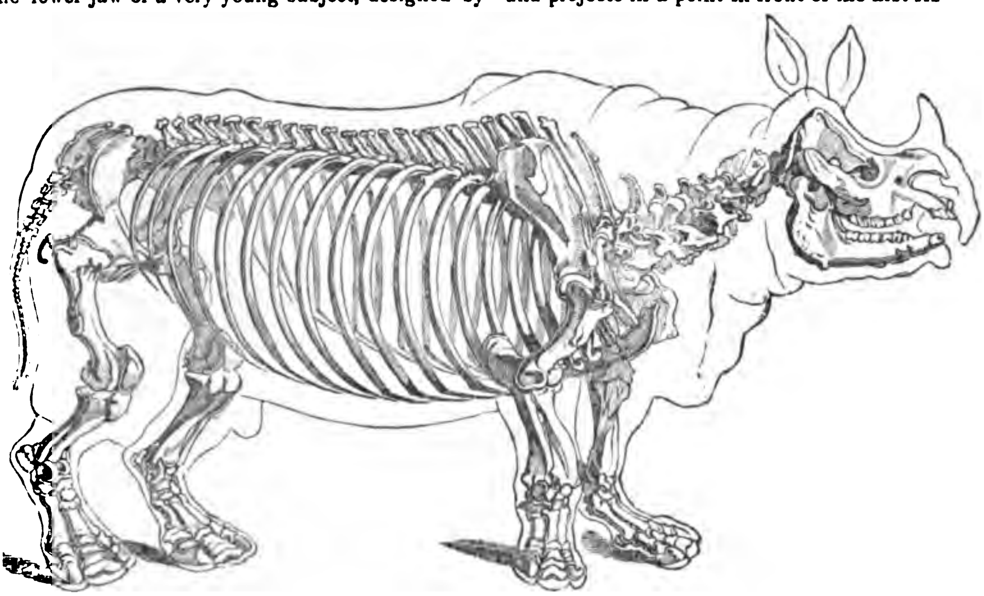
Dental Formula:—Incisors $\frac{4}{4}$; Canines 0; Molars $\frac{7-7}{7-7}$ $= 36$.

Skull.—The pyramidal elevation of the cranium is the first point that strikes the observer on viewing the skull of the *Rhinoceros Indicus*. The next remarkable parts are the *ossa nasi*, which are of a size and thickness without example among quadrupeds: these form an arch or vault which overhangs what may be termed the incisive bones, and gives support to the horn, forming, with the parts of the maxillary bones which carry the incisives, the great nasal notch which distinguishes the skull of these animals. Here three pairs of bones, the nasal, the incisive, and the maxillary, contribute in the Rhinoceros to form the contour of the external apertures of the nostrils; whilst, with the exception of the Tapir, the two first only are employed for this purpose in the other quadrupeds. The form of the molar teeth varies but little from that which characterises those of other species. The upper incisors are very much compressed, and placed obliquely at a very considerable angle: the lower incisors are large, pyramidal, and pointed, and between them are two very little incisors, which are supposed never, or hardly ever, to cut the gum. There are also two little incisors on each side of the two upper great ones; but these are, on the contrary, on the outside of the large incisor teeth. The form of the lower incisor teeth reminds the observer of the instrument generally used by husbandmen for extracting *Docks* (*Rumex*) from their pastures, and they appear to be calculated for uprooting plants, as well as tearing or stripping up branches or stems of shrubs or trees. In the case of uprooting, the nipper-like operation of the two great upper incisors, as opposed to the lower ones, would materially assist the extraction.

The number of molar teeth on each side often varies in different individuals, though there are never more than twenty-eight. The reason of this is well explained by Cuvier.

'All herbivorous animals,' says Cuvier, 'beginning with the horse, wear their teeth to the root; because in proportion as the crown diminishes by trituration, the alveolus is filled, and pushes the root out. When this tooth is composed of two branches, as in the Rhinoceros, and the body of the tooth is entirely used, there remain two stumps of root: these stumps are shed one after the other, being constantly diminished by the trituration, and pushed out by the growth of bone in the interior of the socket. In time the sockets themselves disappear. This is what happened to our Rhinoceros' (the Paris skeleton of *Rhinoceros Indicus*); 'he had already lost his first molar on each side, and the alveoli of it were nearly effaced; he had worn the next molar to the root, and had on one side lost even one of the stumps of the root, whilst both the stumps of the other side remained. But if this Rhinoceros had lost molars by age, he had not gained incisors: that happens not to the Rhinoceros more than to other animals who grow old. The two small intermediate incisors of the lower jaw exist from the period of youth, as may be seen in the head given to the cabinet by M. Adrian Camper; and still better by the end of the lower jaw of a very young subject, designed by his father, in the "Acta Petropolitana" for 1777, and given here after nature: but they always remain hidden under the gum, and this is the reason why Meckel did not see them in the living animal, whilst they are manifest in the skeleton. Mr. Thomas, a surgeon of London, who has published some anatomical observations on the One-horned Rhinoceros, also found these small teeth in the skeleton of an individual four years old. But what no one, to my knowledge, has yet published, is that the Rhinoceros has, at a certain period of its life, two similar incisors on the upper jaw; only they are on the outside of the large ones, whilst in the lower jaw they are between the large ones. This might have been inferred from the figure of the intermaxillary bone of a very young Rhinoceros, given by Camper (the father) in the "Acta Petropolitana," vol. i., pl. ix., fig 3, and which I reproduce more complete, pl. v., fig. 3. I even thought once that this character necessarily indicated another species; but in examining the drawings of the anatomy of our Rhinoceros, made with the greatest care by Maréchal, under the inspection of Vicq. d'Azyr and Mertrud, I discovered the figure of a very small tooth outside the great incisor of the right side; and I saw in the explanation which accompanies the drawing, and which is written by Vicq. d'Azyr with his own hand, that there was, in fact, a small tooth on this side which was wanting on the other; I ran to the skeleton, and there found the remains of the alveolus on one side; but the tooth, already too much loosened (déracinée), was lost during the maceration; on the other side the alveolus itself was effaced.' (*Ossemens Fossiles.*)

There are 56 *vertebræ* in all—7 cervical, 19 dorsal, 3 lumbar, 5 sacral, and 22 coccygian. The transverse apophyses of the atlas are very great and very wide, and without obliquity, so that their contour is nearly rectangular, which distinguishes them from those of the Hippopotamus; their extreme size distinguishes the atlas of the Rhinoceros from that of the Elephant still more clearly. The spinous process is only a large tubercle, and below the body of the vertebra is a small longitudinal crest. There are nineteen pairs of ribs, seven of which are true: they are easily recognised by their proportional thickness and the great arch formed by their curvature. The first pair are soldered together below. The sternum in the adult is composed of four bones; the first is compressed into a ploughshare-shape, and projects in a point in front of the first rib



Skeleton of Rhinoceros Indicus.

Of the *anterior extremities* the following parts are remarkable. The *scapula* is oblong; its greatest width is at its upper fourth; its posterior border is elevated and thickened at this point. The crest has a very projecting apophysis at its upper third, directed a little backwards; this crest terminates at the lower fourth of the scapula, and consequently there is no acromion; a tuberosity occupies the place of a coracoid process, and the glenoïd cavity is nearly round. This configuration distinguishes the scapula or blade bone of the Rhinoceros from that of other great quadrupeds; that of the Elephant, for example, forms a nearly equilateral triangle, and the spine a great recurrent apophysis. The widely crested *humerus* is very remarkable, and distinguishable from that of every other quadruped of the same size, but the carpus is formed after the same model as that of the Tapir and the Horse; though the Rhinoceros and the Tapir resemble each other more than they respectively resemble the horse in this part of the skeleton. The anterior face of the semilunar bone is square, and not pointed above, as in the Hippopotamus. None of the bones of the anterior extremities are liable to be confounded with those of animals of the same size, and though their greatest resemblance is to those of the Tapir, the smallness of those of the latter makes a sufficient distinction.

The *posterior extremities* present the following remarkable parts. The *pelvis* is extremely wide, and that of the Elephant alone among living quadrupeds resembles it; but the pelvis of the Rhinoceros is at once distinguished by its forked spine. The angle of the *os ilium*, which reaches the sacrum, is besides more elevated, and its neck much longer and narrower. The external edge of this bone is nearly as great as the internal, whilst in the Elephant it is much smaller. The crest of the *pubis* commences from the top of the ossa ilii. The *oval holes* are wider than they are long. The tuberosity of the *ischium* is very large above, and in the form of a hook. The *femur* is, if anything, more remarkable than the *humerus;* its upper part is extremely flattened from before backwards; the eminence which Cuvier calls the third trochanter, projects extremely, and forms a hook, which ascends to touch a hook descending from the ordinary grand trochanter, so that there is an oval hole between these two eminences. The *tibia, fibula, tarsus*, and the upper part of the *metatarsus* are constructed upon the plan of those of the horse; but the pulley of the *astragalus* is wider, more oblique, less deep, and its posterior internal angle is obliquely truncated; the astragalus touches the *cuboïd bone* by a rather wide surface; the *scaphoïd* and the third *cuneiform bones* are less flattened; the second *cuneiform* and the *cuboïd* larger. In these points the Rhinoceros resembles the Tapir more than the Horse, and indeed were it not for size would be hardly distinguishable from the former; but it differs from both in having a larger and stouter *calcaneum*. Its anterior or astragalian surface is triangular. The *astragalus* has two large facets; that of the inside is prolonged into a tail-like process all along the lower edge of this surface, as in the Tapir. In the Horse the third facet towards the external angle is distinct. The facet, which touches the cuboïd bone, is very small. The *cuboïd bone* has a long and large protuberance behind, which does not exist in the Horse. On the inside of the foot is a similar one, produced by a supernumerary bone attached to the scaphoid, the internal cuneiform and the internal metatarsial bones, which represents at once the first cuneiform and the thumb in its entirety. This bone exists only in the Tapir and in the Horse; but in the latter it is promptly soldered to the second cuneiform bone. The scaphoïd bone then has three articular facets on its inferior or rather metatarsial face; the third cuneiform or internal bone is much smaller than the other. The *phalanges* are all wider than they are long; the second phalanx of the middle toe is especially short. The last are channelled like those of the hoof of a horse. (Cuv.)

In comparing the osteology of the Two-horned Rhinoceros (*Rhinoceros Africanus*) of Africa and *Rhinoceros simus* with that of the One-horned Rhinoceros of Java and that of the One-horned Rhinoceros of India, and the relations of the osseous parts of those species to each other, we commence with

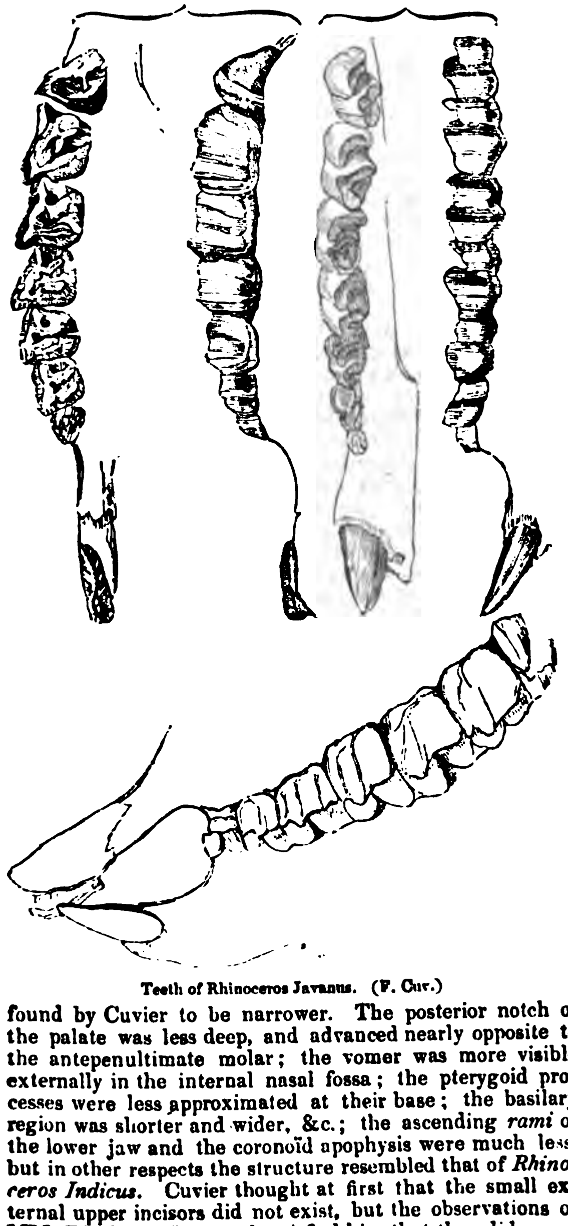
The Two-horned Rhinoceros of the Cape.—The following differences appear on examining the skull:—I. On its upper surface the horizontal contour of the bones of the nose is rounded in the Cape species, and almost extravagantly so in *Rhinoceros simus*, whilst in the one-horned species it is pointed. A deep furrow marks their suture in the first. The space between the post-orbital apophyses is convex in *Rhinoceros Africanus*, or *Bicornis*, transversely concave in *Rhinoceros Indicus*. From this point up to the occipital crest the skull of *Rhin. Africanus* appears longer, because this crest is directed obliquely backwards, whilst it is vertical in *Rhin. Indicus*. The temporal fossæ are less approximated in *Rhin. Africanus*, which leaves the upper and truncated part of the occipital crest wider. The zygomatic arches are less separated backwards in *Rhin. Africanus*, whilst in *Rhin. Indicus* they form a salient angle, which, joined to the difference of the bones of the nose, makes the general horizontal contour of the skull of *Rhin. Indicus* triangular, whilst that of *Rhin. Africanus* and *Rhin. simus* is oblong. The skull of the latter agrees generally with that of *Rhin. Africanus*, but the bones of the nose are prodigiously wide and flattened in front. II. The principal differences in the profile relate to the form of the incisive bones, which in *Rhin. Indicus* advance as far as the bones of the nose, and have above a particular apophysis: in *Rhin. Africanus* and *Rhin. simus* the incisive bones are each reduced to a small oblong piece. Again, a principal difference exists in the convexity of the suborbital space of the skull of *Rhin. Africanus* and *Rhin. simus*, already noticed with regard to the upper surface; and also in the elevation of the occipital crest of *Rhin. Indicus*, and its low position in *Rhin. Africanus* and *Rhin. simus*, whence it results that at an equal distance between the occipital condyles and the muzzle, *Rhin. Indicus* has the upper part of the skull much shorter than *Rhin. Africanus* and *Rhin. simus*. III. On the lower surface, besides the differences which result from the form of the zygomatic arches, the direction of the occipital crest, and that which the difference of the incisive bones produces on the front of the palate, it may be observed that the series of molars is longer in *Rhin. Africanus* and *Rhin. simus*, and that it converges anteriorly with that of the opposite side. In *Rhin. Indicus* the two rows of molars are parallel or nearly so: the palatine notch is pointed anteriorly in *Rhin. Africanus*, and rounded in *Rhin. Indicus;* in both it advances to the penultimate molar: the basilary region is longer in *Rhin. Africanus*, so that it gains in length behind what it had lost before. IV. The posterior surface; which is demi-elliptical, and higher than it is wide in *Rhin. Indicus*, and rather wider than it is high in *Rhin. Africanus* and *Rhin. simus*, in which last the occipital foramen is wider than it is high; whilst in *Rhin. Indicus* those proportions are reversed. The principal differences of the lower jaws are (besides the length which precedes the molars, which is much less in *Rhin. Africanus* and *Rhin. simus* than in *Rhin. Indicus*), 1st, that the series of molars is longer in the African species; 2nd, that the rising branches are much less high; 3rd, that the coronoid apophyses are much shorter, less pointed, and less directed forwards; 4th, that the dental branches are much more convex externally. The upper molars of the African species taken separately are much larger than those of the two one-horned species, and may be distinguished because their posterior border being less elevated, the notch of this border does not change into a fosset, as in the two one-horned species, but remains a true notch, at least till the tooth is worn to a certain extent. There are also other differences in the bones of the anterior and posterior extremities of *Rhin. Africanus*, which our limits will not permit us to detail, but which are pointed out by Cuvier,* who has noticed the other differences above alluded to, excepting those relating to *Rhin. simus*, and which will be obvious on an inspection of the skeleton.

Skull of Rhinoceros bicornis.

The One-horned Rhinoceros of Java (*Rhinoceros Javanus*) resembles less, in the bones of the extremities, the *Rhinoceros Indicus*, than does the *Rhinoceros Africanus;* which, as Cuvier observes, is remarkable. But in the skull the resemblance to that of *Rhinoceros Indicus* is striking, though there are still remarkable differences. The whole cranium, for instance, is less, and the zygomatic arches, the orbits, and the nasal bones, which terminate in a sharp point, are less developed. The post-orbital apophysis can hardly be traced. The occipital crest is less elevated; there is no apophysis on the superior edge of the incisive bones; the orbit has a more forward position; the posterior base of the zygomatic arch is less approximated to the occiput; the region of the external opening of the ear is wider; the descending part of the occipital arch, which is trenchant in *Rhinoceros Indicus*, is here stout and obtuse. The posterior

* But Cuvier observes that these differences (with the exception of those of the head and teeth) are of such little importance that he would not affirm of them that it might not exist as well between two individuals of *Rhin. Javanus* as between *Rhin. Indicus* and *Rhin. Africanus;* nor would he venture to found a specific character on one of them taken by itself.

surface of the skull of *Rhinoceros Javanus* is wider than it is high: in *Rhinoceros Indicus* it is just the reverse; and the same difference exists in the dimensions of the occipital hole. Cuvier further observes that the upper contour of the occipital crest is notched in the cranium of the skull of *Rhinoceros Javanus* in the Paris collection, and convex in that of *Rhinoceros Indicus*. On examination of the lower surface, the incisive bones of the Javanese skeleton were



Teeth of Rhinoceros Javanus. (F. Cuv.)

found by Cuvier to be narrower. The posterior notch of the palate was less deep, and advanced nearly opposite to the antepenultimate molar; the vomer was more visible externally in the internal nasal fossa; the pterygoid processes were less approximated at their base; the basilary region was shorter and wider, &c.; the ascending *rami* of the lower jaw and the coronoïd apophysis were much less, but in other respects the structure resembled that of *Rhinoceros Indicus*. Cuvier thought at first that the small external upper incisors did not exist, but the observations of MM. Diard and Duvaucel satisfied him that they did.

Skull of Rhinoceros Javanus.

Cuvier found the great upper incisors more delicate, so to speak, and situated more in parallel with each other than those of *Rhinoceros Indicus*: the lower incisors were in the form of a triangular pyramid, terminated forwards in a sharp point, with their lower edge rounded, and their upper surface worn by the friction of the upper incisors. Cuvier justly supposes that the difference between these great lower incisors, which were sharp and pyramidal, as he has well described them, in the Javanese species, and the truncated great lower incisor teeth of *Rhinoceros Indicus*, was the consequence of age only. The small intermediate incisors in the Javanese species were like those in *Rhinoceros Indicus*. There is not much difference between either the upper or the lower molar teeth of the two one-horned Asiatic species; but the scapula of the Javanese Rhinoceros is very different from that of *Rhinoceros Indicus*; for it is wider in the middle; it has the anterior edge rounded into a more convex arch; the salient angle of the spine has a much higher position, it is wider and, especially, longer, directed backwards on the plane of the bone, and so that its point answers to the posterior border. It is also much lower below, and the coracoïd tubercle is much larger than that of *Rhin. Indicus*. Cuvier further remarks that the *humerus* of *Rhin. Javanus* is distinguishable at the first glance by its bicipital obliquely hollowed canal, and other differences; the *ulna* is narrower below, and the olecranon is more elongated and directed more according to the axis of the bone: the *radius* exhibits but little difference. The bones of the *carpus* were found to resemble those of *Rhin. Indicus* more than those of *Rhin. Africanus*; with the exception of the unciform bone, which is higher in proportion. Cuvier found that the pelvis of *Rhin. Javanus* differed from that of the other species principally in having the external spine not forked. There is a slight difference in the femur, principally in what Cuvier terms the third trochanter, which is placed on the middle of its external side, is wide, curved forwards, but not ascending towards the great trochanter, which has no point to meet it. The notch or space formed by the two is not closed, in consequence, externally; but it is as large as in *Rhin. Indicus*. The lower head of the bone is widened backwards. Cuvier found the principal difference of the *tibia* to consist in its greater length and the depth of the anterior canal of the upper head of the bone. But the tarsal bones were found by Cuvier to exhibit very marked specific differences: the *astragalus*, below its anterior pulley, has an oval deep fossa which is wanting in the other species. The internal edge of the pulley is also shorter, and descends more obliquely forwards. The lower apophysis of the calcaneum is less stout in proportion. The cuboid bone is less elevated, and all the bones of the metatarsus are shorter, wider, and more flat; so that, as Cuvier remarks, the feet of this species must be shorter and wider in proportion than the others.

Before we close our short notice of the osteology of this genus, we must refer the reader to the *Catalogue of the Contents of the Museum of the Royal College of Surgeons in London*, part iii.; and to the Museum itself for a fine collection of the osseous parts and horns of these animals, Nos. 813 to 839 inclusive. Among them will be found a skeleton of the Sumatran Two-horned Rhinoceros (Sir Stamford Raffles), and the very skulls of that species which were figured by Bell (*Phil. Trans.*, vol. lxxxiii., pl. 2, 3, 4 (No. 1815). There are also good examples of *Rhin. Indicus* and a very fine skull of *Rhin. simus* from the collection of Mr. Delafons.

Digestive Organs.—The stomach of these animals is simple, their intestines very long and the cæcum very large. Sparrman, who dissected a Cape Two-horned Rhinoceros as well as his position and his Hottentot assistants would permit, remarks that the viscera most resemble those of a horse; though the stomach did not in the least resemble that of a horse, but rather that of a man or a hog. It was four feet in length and two feet in diameter; and to this viscus was annexed an intestinal tube twenty-eight feet in length and six inches in diameter: at three feet and a half from the bottom was a large cæcum, 'if,' says Sparrman, 'I may so call a viscus, which at its upper end was of the same width as the stomach, viz. two feet, and above twice the length, that is, eight feet and a half, and lay on the spine of the back, being attached to it at both ends, after which it was contracted into a rectum six inches in width and eighteen in length.' The liver was three feet and a half in breadth, but in depth (taken as if the animal were in a standing position) two feet and a half. It consisted of three larger and perfectly distinct globes, almost equal in size, and of a small lobe besides, which projected to about a foot from the concave side of the liver, at the middle of its upper edge. There was no gall-bladder nor any trace of it. In this the structure of the Rhinoceros resembled that of the horse; though some have considered the large hepatic duct of the horse as a gall-bladder. The contents of the stomach, which was very much distended, were entirely without offensive smell, and perfectly fresh and sweet, consisting of masticated roots and small branches of trees, some of them as big as the end of a man's finger. There was evidence that the animal had also eaten a great quantity of succulent plants, among which Sparrman thought he recognised two or three which were harsh and prickly. 'The whole of this mass,' says he, 'diffused around a very strong and not disagreeable aromatic odour, which in a great measure took off the stench of the putrid viscera. Might it not be some peculiar herb, or, perhaps, the root only of an herb, with which I was entirely unacquainted, that produced the greatest part of the aromatic flavour? In the excrements of this animal, which were four inches in diameter, and in other respects resemble those of a horse, though they are of a much drier nature, there is usually seen a quantity of bark and fibres of trees, a circumstance that the hunters pay attention to; and by that means are able to distinguish it from the dung of the Hippopotamus, an animal that feeds only on grass. I thrust my hand into this creature's mouth, which was half open, and found the tongue perfectly soft, which is in direct contradiction to the common notion, viz. *quod lambendo trucidat*. I was likewise not a little astonished to find no fore-teeth in any of these carcasses of the Rhinoceros, although one of the three beasts seemed to be old; and, in fact, this animal has little room for fore-teeth, as the mouth goes off so sharp at the fore-part, that in that place it is only an inch and a half broad. Besides, it has no occasion for any teeth there, as the lips, like the skin, are of that extreme hardness, that it is able to clip off the tops of plants and shrubs with them, and that with so much the greater ease, as the under jaw goes within the upper; so that this species of Rhinoceros is probably capable of laying hold of its food with its lips and conveying it into the mouth, with the same ease and dexterity as Dr. Parsons observed in the common Rhinoceros on a similar occasion.' The spleen was hardly a foot broad, but full four feet long.

Circulating and Respiratory Organs.—The heart was a foot and a half in length and the breadth was not much less. The right lobe of the lungs had an incision in it (probably made by the Hottentots who exenterated the animal, or by the shot, which passed through the great blood-vessels of the lungs, and mortally wounded the animal), but was in other respects undivided and entire: it was two feet in length. The left lung was subdivided into two lobes, the smaller of which was next to the base of the heart.

Urinary System.—The kidneys were a foot and a half in diameter.

There are, we believe, in the museum of the Royal College of Surgeons many preparations of the soft parts of a *Rhinoceros Indicus* which belonged to Mr. Wombwell, and died at Canterbury in the beginning of the year 1838. We had been in hopes that this dissection, which was made by Professor Owen, would have been given to the scientific world as a pendant to the admirable 'Memoir on the Pearly Nautilus,' and in a similar shape.

Integuments and Horns.—The hide of the rhinoceros is perhaps as thick as, if not thicker than, that of any other pachydermatous animal. The horns, solid as they are apparently, consist actually of congregated parallel horny fibres. Fine examples of these horns, and of their gradual increase, will be found in the Museum of the College of Surgeons.

Asiatic Rhinoceroses.

Rhinoceros Indicus (*Rhinoceros Unicornis*, Linn.).

Specific Character and Description.—Dental Formula: see above. A single horn on the nose. Skin naked, very thick, of a dull deep purplish grey, marked with sub-elevated, rounded, and other inequalities, and remarkable for the deep folds which it forms behind and across the shoulders, and before and across the thighs, &c. There are a few stout, stiff, horny, and smooth hairs on the tail and on the ears.

We have seen that a one-horned rhinoceros, this species probably, was shown at Rome by Pompey: that it was well known in the time of Domitian appears from the following epigram (Martial, 'De Spectaculis Libellus,' *Ep.* ix.):*

> 'Præstitit exhibitus tota tibi, Cæsar, arena,
> Quæ non promisit prælia rhinoceros.
> O quam terribiles exarsit pronus in iras!
> Quantus erat cornu, cui pila taurus erat.'

The best early figure of *Rhinoceros Indicus* known to [illegible] is that of Bontius, which, though somewhat exaggerated [illegible] the draughtsman about the lip, and furnished with [illegible] claws instead of broad nails, gives in general a correct id[illegible] of the animal. Bontius states that he has seen the anim[illegible] a thousand times, both in confinement and in its na[illegible] wilds, and he states that he gives the figure to correct t[illegible] error of those painters who have depicted the animal [illegible] 'scutatum et squamis obsitum.' He states the follow[illegible] anecdote of its fury when provoked:—A party on horseba[illegible] had proceeded to a wood, when in a marshy place th[illegible] came upon a rhinoceros and her young one. The moth[illegible] on seeing them, arose and drove her young one towards th[illegible] wood, and when it stopped as if in sport, pushed it forw[illegible] with her snout. One of the company, out of a brav[illegible] rode up, and drawing his Japanese sword, cut at the hin[illegible] parts of the old one, but the blows did not penetrate [illegible] account of the hide, and some whitish marks only appear[illegible] The mother bore all patiently till her young one was sa[illegible] hidden in the bushes and brushwood. Then the scene w[illegible] changed. The irritated beast turned suddenly on her p[illegible] secutor, whose life was saved by his frightened horse, w[illegible] galloped back to the party followed by the infuriated r[illegible] ceros overturning trees and everything in her way.

As soon as she saw the rest of the company, she atta[illegible] them, and they avoided her by getting behind two g[illegible] trees, scarcely two feet apart, between which the rhino[illegible] in the blindness of her rage rushed, making them tre[illegible] like reeds. Whilst she was thus entangled, they used t[illegible] fire-arms with fatal effect, and slew her. The rash [illegible] who attacked her by himself had a very narrow escape; [illegible] she turned short upon him with a horrible roar 'cum [illegible] inani grunnitu et stridore,' and seized him by the [illegible] which fortunately for him was made of light stuff, and g[illegible] way. Had it not been for its tearing, 'actum de eo fu[illegible]' as Bontius says, in plain English it would have been all [illegible] with him. The same author, though so anxious to dis[illegible] error, states, in a previous part of this chapter, *De [illegible] sive Rhinocerote*, that when the animal has prostra[illegible] a man, it kills him by licking him with his rough ton[illegible] and tears off both skin and flesh, even to the bones: '[illegible] etiam,' he adds, 'spinis ac vepribus libentissimè vesc[illegible] and he quotes the lines,—

> 'Lingua virum occidit lambendo rhinocerotis,
> Aulica falsidici sic quoque lingua necat.'

It is to this most probably that Sparrman alludes ab[illegible]

Pennant, who is decidedly of opinion that this spec[illegible] the Unicorn of holy writ, and the Indian ass of Ari[illegible] (p. 463), says that it loves shady forests, the neighbour[illegible] of rivers, and marshy places; that it brings forth one y[illegible] at a time, and is very solicitous about it; that it is quie[illegible] inoffensive, but when provoked, furious, very swift, an[illegible] dangerous. 'I know a gentleman,' he continues, 'who [illegible] his belly ripped up by one, but survived the wound.' Pe[illegible] nant gives the name of this person.†

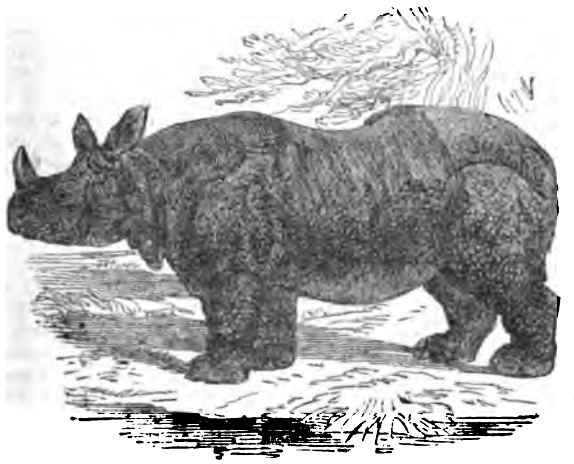
The rhinoceros described by Dr. Parsons came to L[illegible] in 1739 from Bengal. It is stated that though but [illegible] years old, the expenses of his food and his voyage am[illegible] to near 1000*l.* sterling. He had daily seven pounds of [illegible] mixed with three pounds of sugar: this was divided [illegible] three portions. Hay and green herbs were also giv[illegible] him, but he preferred the latter. He drank largely of wa[illegible] taking a great quantity at a time, was peaceable whe[illegible] hungry or provoked, and allowed himself to be han[illegible] When however he wanted to eat, or was irritated b[illegible] person, he became unruly, and in both cases he was on[illegible] be appeased by food. When he was enraged, he sp[illegible] forward, reared himself up, and pushed violently with [illegible] head against the walls. Dr. Parsons observed these mo[illegible] ments produced by rage or impatience, especially in [illegible] morning before his rice and sugar were brought to [illegible] The vivacity and promptitude of these actions led the d[illegible] to think that the animal was altogether unconquer[illegible]

* See also lib. [illegible], *Ep.* 4, xiv., p. 52, 53, &c.

† Charles Pigot, Esq., of Peploe, Shropshire, at that time in the [illegible] service.

and that he could easily overtake any man who should offend him. Dr. Parsons also observed that this rhinoceros hearkened with a sort of continual attention to any noise; so that even if he was drowsy, employed in eating, or in satisfying other urgent wants, he started instantly, and gave attention till the noise had ceased. The *Rhinoceros Indicus* now in the Zoological Society's garden at the Regent's Park has been observed to listen with attention; and, when out, to be thrown into great excitement by the noise of the roller upon the contiguous gravel walk, charging down towards it, and rearing himself up against the fence with great violence.

The rhinoceros brought to this country in 1790 is the subject of an interesting account by Mr. Bingley, in his 'Animal Biography.' When it arrived it was about five years old, was tolerably tractable, would walk about at its keeper's command, and allowed the visitors to pat his back and sides. He was allowed twenty-eight pounds of clover, about the same quantity of ship-biscuit, and a great quantity of greens daily. Twice or thrice a-day five pails of water were given to him. The vessel out of which he drank contained about three pails, and each time as the animal drank the vessel was filled up. He never ceased his draught till the vessel was exhausted. He was fond of sweet wines, and it is stated that he would drink three or four bottles in a few hours. If he saw any person with fruit or any favourite food, he appeared anxious for it, and then uttered a sound something like the bleating of a calf. This animal died of inflammation arising from slipping the joint of one of his fore-legs. It is recorded that the incisions made through his skin, on the first attempts to relieve him, were invariably found to be healed in twenty-four hours. His death happened near Portsmouth, and the stench was so great that the mayor ordered the body to be immediately buried, which was done on Southsea Common. There it lay for about a fortnight, when it was dug up again to preserve the skin and the most valuable of the bones; but the persons employed were nearly overpowered by the effluvia.



Rhinoceros Indicus.

Rhinoceros Indicus.

The renowned combats between the Elephant and Rhinoceros handed down to us from the antients are generally considered to be tinged with fable. but there is no doubt that contentions do occur between them in a state of nature. Soon after the arrival of the Rhinoceros now in the Regent's Park, he contrived to get into the apartment of the old Elephant, but there was no proof of any actual hostility. At present they are the best friends in the world, and it is amusing to see how quiet the Rhinoceros will stand whilst his great friend scrubs his back with his trunk, and occasionally gratifies himself by a sly pull at his tail to make the Rhinoceros turn his head, if his attention is taken off by visitors.

Locality, Food, &c.—This species inhabits the East Indies, especially beyond the Ganges. It is recorded as having been found in Bengal, Siam, and Cochin-China. Shady forests, the neighbourhood of rivers, and marshy places are favourite localities. Their ordinary food consists of herbage and the branches of trees. The flesh is said to be not unpalatable. Our figure is taken from the living animal in the garden of the Zoological Society, but the horn is taken from a perfect specimen; for the animal, though a fine one, and in excellent general health, has ever since its arrival, and from the first growth of the horn, constantly employed itself in rubbing it down, so as to prevent its proper increase.

Rhinoceros Javanus, Cuv.

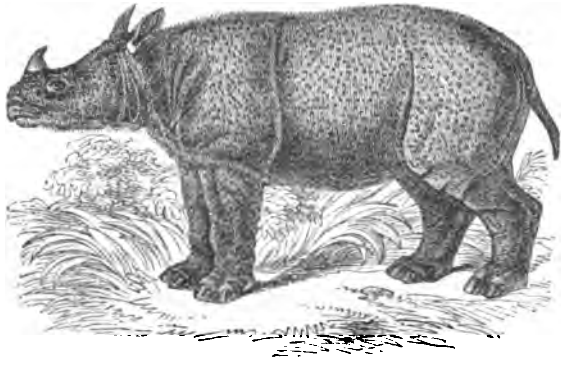
Specific Character.—One-horned; folds of the neck obsolete; scutules of the skin angled at the margin, concave in the middle, and furnished with a few short bristles margin of the ears and under side of the tail hairy.

Description.—Dr. Horsfield, who had an opportunity during his residence at Surakarta, the capital of the Javanese empire, to examine an individual taken during infancy and kept in confinement, or rather in a state of domestication, gives a good figure of it, observing that the drawing from which the plate is taken, though deficient in some points that the skilful pencil of Mr. Daniell would have supplied from the living animal, exhibits, with scrupulous accuracy, its form and proportions. In 1817 this individual measured nine feet in length, and was four feet three inches high at the rump; and Dr. Horsfield remarks, that the Rhinoceros figured by M. F. Cuvier (of which a reduced copy is given below), brought to Europe from the British possessions in India, was higher in proportion to its length, and its form was more unwieldy, the entire length being seven feet, and the height four feet ten inches. The head of the animal seen by Dr. Horsfield was strongly attenuated to the muzzle, and had a triangular form; the flexible lip was considerably lengthened, and the sides of the head were marked with protuberances or scutula, resembling those on the body, but no great roughnesses or folds were apparent. The marks of distinction afforded by the folds of the external covering were less evident than those afforded by the form of the body and the attenuated head; but the folds on the whole appeared less rough or prominent than in *Rhinoceros Indicus;* those of the neck were comparatively smaller; and the posterior fold, which had an oblique direction towards the spine, was less extended. The thick covering of Dr. Horsfield's animal was divided on the surface into small tubercles or polygonous scutula; and a few short bristly hairs rose from a slight depression in the centre. The ears were bordered with a series of long stiff bristles, closely arranged; and a similar series of bristles also extended along the tail, underneath, through its whole length.

Locality, Habits, Manners, &c.—Gregarious in many parts. Dr. Horsfield states that it is not limited to a particular region or climate, but that its range extends from the level of the ocean to the summit of the mountains of considerable elevation. Dr. Horsfield noticed it at Tangung, near the confines of the Southern Ocean, in the districts of the native princes, and on the summit of the high peaks of the Priangan regencies, but it prefers high situations. 'It is not,' adds Dr. Horsfield, 'generally distributed, but is tolerably numerous in circumscribed spots distant from the dwellings of man and covered with a profuse vegetation. On the whole it is more abundant in the western than in the eastern districts of the island. Its retreats are discovered by deeply excavated passages which it forms along the declivities of mountains and hills. I found these occasionally of great depth and extent. In its manners the Rhinoceros of Java is comparatively mild, It is not unfiequently met in the wilds by Europeans and by natives. No instance of its showing a disposition to make an attack has come to my knowledge. Being the largest animal in Java, its passions are not roused, as in many parts of India, by contentions with the elephant. It is rarely seen in a domestic state, but is occasionally decoyed into pits and destroyed. Our animal rambles chiefly at night, and often occasions serious injury to the plantations of coffee and pepper, which are laid out in the fertile districts selected for its retreats. The horns and skin are employed for medicinal purposes by the natives.'

The domesticated individual above alluded to by Dr. Horsfield was taken while very young, in the forests of the province of Keddu, and was conveyed to the residency at Magellan, in the year 1815 or 1816. By kind treatment it soon became domesticated to such a degree, that it permitted itself to be carried, in a large vehicle resembling a cart, to the capital of Surakarta. 'I saw it,' says the Doctor, 'during its conveyance, and found it perfectly mild and tractable. At Surakarta it was confined in the large area or square which bounds the entrance to the royal residence. A deep ditch, about three feet wide, limited its range, and for several years it never attempted to pass it. It was perfectly reconciled to its confinement, and never exhibited any symptoms of uneasiness or rage, although, on its first arrival, harassed in various ways by a large proportion of the inhabitants of a populous capital, whose curiosity induced them to inspect the stranger of the forest. Branches of trees, shrubs, and various twining plants were abundantly provided for its food; of these the species of *Cissus* and the small twigs of a native fig-tree were preferred. But plantains were the most favourite food, and the abundant manner in which it was supplied with these by the numerous visitors tended greatly to make the animal mild and sociable. It allowed itself to be examined and handled freely, and the more daring of the visitors sometimes mounted on its back. It required copious supplies of water, and, when not taking food, or intentionally roused by the natives, it generally placed itself in the large excavations which its movements soon caused in the soft earth that covered the allotted space. Having considerably increased in size, the ditch of three feet in breadth was insufficient for confining it, but, leaving the inclosure, it frequently passed to the dwellings of the natives, destroying the plantations of fruit-trees and culinary vegetables which always surround them. It likewise terrified those natives that accidentally met with it, and who were unacquainted with its appearance and habits. But it showed no ill-natured disposition, and readily allowed itself to be driven back to the inclosure, like a Buffalo. The excessive excavations which it made by continually wallowing in the mire, and the accumulation of putrefying vegetable matter, in process of time became offensive at the entrance of the palace, and its removal was ordered by the emperor to a small village near the confines of the capital, where, in the year 1821, it was accidentally drowned in a rivulet.' (*Zoological Researches in Java.*)

This species is the *Warak* of the Javanese, and *Badak* of the Malays and of the inhabitants of the western parts of Java. (Horsfield, *Ibid.*)



Rhinoceros Javanus. (F. Cuvier.)

Marsden, in his 'History of Sumatra,' states that the Rhinoceros, *Badak*, both that with a single horn and that with a double horn, are natives of the woods (quære tamen). ...ds that he does 'not know anything to warrant the ... told of the mutual antipathy and the desperate encounters of these two enormous beasts.' The horn, he a... is esteemed an antidote against poison, and on that acc... formed into drinking-cups.

The animal from which the figure was taken was a fe... The horn had been worn down by use, and the deficiency is ... plied, in the cut, from Dr. Horsfield's figure. M. F. C... says that the upper incisors are four in the young, tw... each intermaxillary, very much approximated to each ot... they are then small and nearly cylindrical; they soon f... and are not replaced in adults except by two teeth, 'lor... d'arrière en avant, minces de dehors en dedans, sortai... peine des gencives, dont le tranchant est mousse et arr... et qui sont opposées à la partie antérieure des longue... sives inférieures.'

Rhinoceros Sumatrensis, Cuv. (*Rhinoceros Sumatra*... Raffles).

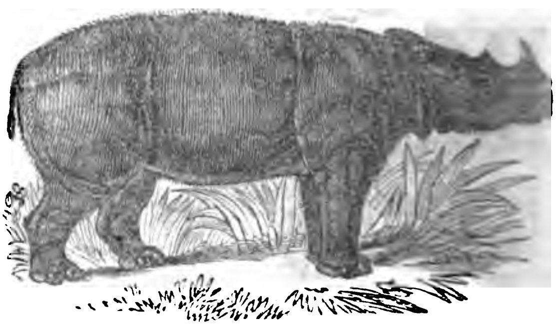
Specific Character.—Four great incisors, as in the preceding species, but hardly any folds on the skin. ... is hairy; a second horn behind the ordinary one.

The first satisfactory indication of the existence o... species occurs in Pennant, who imagined that the t... horned species of Sumatra was identical with *Rhin... bicornis*, the only African species then known. He qu... the following remark of Mr. Charles Miller, who was ... resident in Sumatra:—'I never saw but two of the t... horned Rhinoceros; but I believe they are not unco... in the island, but are very shy, which is the reason the... but seldom seen. I was once within twenty yards of... It had not any appearance of folds or plaits on the ... and had a similar horn resembling the greater, and... that, a little turned inward. The figure given by Dr. S... man is a faithful resemblance of that I saw.'

Description.—Hide rugose, covered with scattered brown hairs; folds on the shoulders and croup but s... marked; the skin generally rather delicate and nearly w... out folds; head rather elongated: eyes small and br... upper lip pointed and curved downwards; ears sma... pointed, fringed with black short hairs; first horn ... backwards, second smooth and pyramidal, placed a little... front of the eyes.

The first figure was published by Mr. William Bell... 1793.

Locality, Sumatra.



Rhinoceros Sumatrensis. (F. Cuvier.)

African Rhinoceroses.

Till a comparatively late period the *Rhinoceros bico...* of Linnæus (*Rhin. Africanus*, Cuv.) was the only Afr... species distinctly known. The opportunities enjoyed by ... Andrew Smith, and of which he has availed himself so mu... to the advancement of zoology, enabled him to add a th... *Rhinoceros Keitloa*, to the species first recorded and ... described by Mr. Burchell.

We have seen that in the Sumatran two-horned Rh... ceros the folds of the skin are hardly perceptible; in ... African Rhinoceros there are none on the body; so ... the presence of two horns in this genus seems to be a c... dition of the form coexistent with a smooth hide comp... tively without folds. Taking into consideration the ... ferences of the dentition, which are striking as far as ... incisors are concerned, the two horns, and the smoothne... the hide; we think that this genus might be convenie... divided into two groups or subgenera: 1, the one-horn... and 2, the two-horned.

Rhinoceros Africanus, Cuv. (*Rhinoceros bicornis*, Lin...

Specific Character.—Pale yellow brown; horns uneq... in length; neck surrounded with a furrow at the ...

on of the head; eyes brown. Length 10 feet 11 inches. (Smith.)

Description.—Pale yellowish-brown, with tints of purple upon the sides of the head and muzzle; the groins flesh-coloured; eyes dark brown; the horns livid-brown clouded with green; the hairs on the tip of the tail and the margins of the ears deep black.

Head rather deep in proportion to its length, which gives it an appearance of clumsiness beyond either of the other South-African species; the anterior horn directly over the extremity of the nose, the first half nearly perpendicular, the last half slightly curved backwards; the posterior horn conical, and often exhibiting an appearance as if the point of a smaller sized cone had been fixed upon the section of a larger one, which observation to a certain extent might also be applied to the front horn; towards the bases both are rough, and more or less distinctly fibrous; towards the points hard, smooth, and finely polished. Eyes small, the skin surrounding them, as well as that in front of the ears and on the muzzle and the upper and lower lips, deeply cut by narrow wrinkles; the extremity of the upper lip is scarcely produced. The neck is thick, short, and at its junction with the head encircled by a deep furrow formed in the skin; the shoulder with a rudimentary hunch; the body round and heavy, limbs rather shorter in proportion than in *Rhin. Keitloa*. Tail flattened towards the extremity, elsewhere somewhat cylindrical: the upper and lower edges near the tip fringed with thick wiry hair. The surface of the skin rather rougher than in *Rhin. Keitloa*, owing to its being intersected by a great number of wrinkles. The relative lengths of the horns vary a little in different individuals, but the hindermost one in both sexes is invariably much the shortest, and in young specimens it is scarcely visible when the other is several inches in length. In *Rhin. Keitloa* the young have both horns of equal length. (Smith.)

Locality, Habits, Food, Chace, &c.—Sparrman, in his description, exposes the errors of Buffon regarding both this species and *Rhin. Indicus*; especially the opinion that the copulation of the latter takes place *croupe à croupe*. His poetical fancies too touching the impenetrable nature of the skin are freely and justly dealt with by the same learned Swede, who ordered one of his Hottentots to make a trial of this with his hassagai on one of those which had been shot. Though this weapon was far from being in good order, and had no other sharpness than that it had received from the forge, the Hottentot, at the distance of five or six paces, not only pierced with it the thick hide of the animal, but buried it half a foot deep in its body.

Dr. Smith remarks that the present species, under the name of *Rhinoster*, has been familiarly known to the colonists of the Cape of Good Hope ever since 1652. In that year, when the Dutch first formed their settlement on the shores of Table Bay, this animal, he observes, was a regular inhabitant of the thickets which clothed the lower slopes of Table Mountain. 'The abandonment of those spots by this animal as a measure of safety,' says Dr. Smith in continuation, 'probably constituted the commencement of a forced migration, which has continued to extend ever since, and which has led not only to the disappearance of the species from the districts within the present colonial limits, but also in a great measure to its removal from countries beyond those limits, as far as hunters sufficiently armed are accustomed to resort. If a system such as has hitherto prevailed continues to exist, and the larger animals persevere in flying to avoid the effects of fire-arms, the time may arrive when the various species which formerly may have been scattered, each in a peculiar locality of a large continent, will be huddled together; and indeed an advance towards that period is in progress, as may be inferred from the concentration which is at present taking place in the interior of South Africa.

'Though many of the individuals which inhabited the countries where now not a single Rhinoceros is to be seen, were doubtless destroyed, yet it is equally certain that many others escaped, and thereby assisted in adding to the accumulation which is in progress in other localities. Until lately the present was the only species of the genus which was known to be receding from its native country, but of late another has been led to a like course; and the *Rhinoceros simus*, which but a few years ago was common in the neighbourhood of Latakoo, has, since the more general introduction of fire-arms into that country, almost entirely ceased to approach within a hundred miles of it. From a consideration of the various facts which we have collected in relation to the species now under consideration, and which we shall detail more at length elsewhere, we feel disposed to regard it to a certain extent as a prisoner in the country it now inhabits, and are inclined to believe the southern extremity of the continent and the country along the western coast towards Benguela to have once formed its favourite residence.'

Sparrman's account of the contents of the stomach of the individual which he dissected indicates the food on which the animal had lived. Dr. Smith states that, like the *Keitloa*, this species feeds upon brushwood and the smaller branches of dwarf trees, from which circumstance it is invariably found frequenting wooded districts, and in those situations its course may often be traced by the mutilations of the bushes. 'As it feeds but slowly,' says Dr. Smith, 'and besides passes much of its time in idleness, it must be regarded as a very moderate eater, and considering that it appears to be fastidious in the choice of its food, it is fortunate for its comfort that it does not require more nourishment. Of the many shrubs which exist in the locality in which it resides, few comparatively appear formed for its choice, as it is to be seen approaching many and leaving them again without either injuring a branch or plucking a leaf. This evident nicety in the selection of its aliment makes it difficult to imagine how so many large animals as are sometimes congregated together within a very limited space can find sufficient for their consumption. Even admitting that the reproduction of the parts which the rhinoceros may devour takes place with uncommon rapidity in the climates they inhabit, and consequently the shrubs are comparatively soon in a condition to supply another meal; yet, nevertheless, if these animals consumed in proportion to their bulk, they would of necessity be forced to be less particular in the choice of their food.'

Sparrman tells us that the Hottentot or Caffre hunters were accustomed to steal both upon the elephant and the rhinoceros while they were asleep, and wound them in different places at the same time. After this they followed the traces of the animal for one or more days, till it dropped down with weakness, or died of its wounds. Generally however, according to their own account, they poisoned one or two of their darts immediately before they attacked an animal of this size; in which case they had no occasion to wait so many days as they otherwise would, before their prey fell into their hands. A farmer told Sparrman that he had seen an elephant in this manner wounded and dead within twenty-four hours.

Rhinoceros Bicornis, Female and Young. (Smith.)

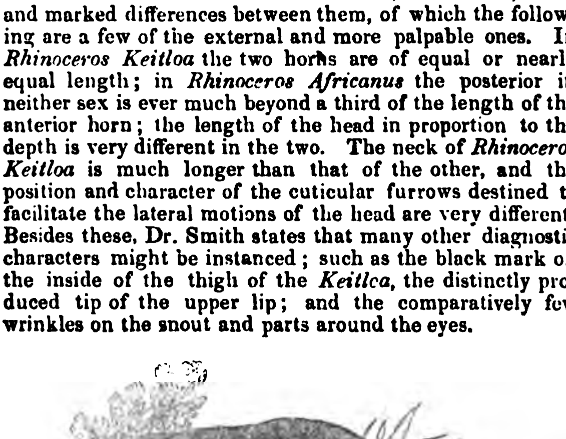
Rhinoceros Keitloa (Smith).

Specific Character.—Pale brownish yellow; the two horns subequal in length, the anterior one cylindrical, the posterior one compressed; anterior part of the upper lip produced and acuminate. Length, body and head, 11 feet and 1½ inches. Height, 5 feet.

Description.—Pale brownish yellow, the brown most distinct upon the head; the inner sides of the extremities towards the body and the groins somewhat flesh-coloured; the inner sides of the knee joint, and the hinder part of the thighs immediately above the joints pale livid black. Eyes dark brown. Horns dark greenish brown.

Figure nearly that of *Rhinoceros bicornis*. Skin destitute of hair, rough and slightly irregular, the surface exhibiting a reticulated appearance, arising from the number of waved or angular fissures by which it is everywhere impressed, but more particularly upon the shoulders and outer surfaces of the hinder extremities. The lower portion of the neck is marked by several wide vertical furrows which admit of the head being turned to either side with greater facility; several of a much smaller size also occur towards the extremity of the muzzle and around the eyes, so as to admit of the upper lip and the eyelids being moved with greater freedom. Head moderately slender; the eyes very small, and sunk in their orbits; the nostrils situated near to the extremity of the muzzle, somewhat oval and rather opaque in relation to the axis of the head. Anterior horn nearly cylindrical, the basal half directed forwards, the distal half slightly curved backwards; the posterior horn towards its base nearly cylindrical, with the distal two-thirds naturally compressed, and having the hindermost edge thinnest. Ears somewhat acuminated, edged with short hairs towards their tips. Legs rather short, knee-joints very large; scarcely any hunch on the shoulders; the neck rather long. Tail cylindrical till within a few inches of the extremity, then naturally compressed and margined above and below by strong short and wiry hair. (Smith.)

Dr. Smith remarks that the only species yet known with which the present could be confounded is the *Rhinoceros bicornis* of authors. There are however, he observes, many and marked differences between them, of which the following are a few of the external and more palpable ones. In *Rhinoceros Keitloa* the two horns are of equal or nearly equal length; in *Rhinoceros Africanus* the posterior in neither sex is ever much beyond a third of the length of the anterior horn; the length of the head in proportion to the depth is very different in the two. The neck of *Rhinoceros Keitloa* is much longer than that of the other, and the position and character of the cuticular furrows destined to facilitate the lateral motions of the head are very different. Besides these, Dr. Smith states that many other diagnostic characters might be instanced; such as the black mark on the inside of the thigh of the *Keitlca*, the distinctly produced tip of the upper lip; and the comparatively few wrinkles on the snout and parts around the eyes.



Rhinoceros Keitloa, Male. (Smith.)

Locality, Habits, &c.—Dr. Smith thinks that it may with propriety be inferred that the *Keitloa* has not, for many years at least, been in the habit of generally extending its range higher than about 25° S. lat. He remarks that we have sufficient evidence that individuals of this species have approached Latakoo, or rather the country some sixty miles to the north of it, in the fact that Mr. Burchell, 'whose merits as a traveller can be best appreciated by those who follow him in the same field, is at present in possession of the horns of an individual which was killed by his hunters.' Dr. Smith further states that the natives at and around Latakoo are only acquainted with two species, viz. *Borili* (*Rhinoceros bicornis* of authors) and *Mohoohoo* (*Rhinoceros simus*, Burch.); and those who were in the employ of the expedition declared, when they first saw the *Keitloa*, that it was not an animal of their country; and at once enlarged upon the points in which it differed from *Borili*. During the discussion an intelligent Moharotsi, who was well acquainted with the animal, approached, called it by its name, and referred Dr. Smith to districts where specimens were found in abundance. As he stated it happened, though everywhere the species appeared rare when compared with the others; and after several months' wanderings it was remarked that only sixty-eight individuals had been seen, eight of which, in one herd (two of them not more than half grown), were disturbed, when feeding near to the banks of a river which the party were descending, by Dr. Smith himself. According to the evidence of the natives given to Dr. Smith, the *Keitloa* is of a very savage disposition, on which account it is more feared than *Borili*, which is also deemed ferocious.

The food of this species consists of small shrubs, or the more delicate branches of brushwood, in collecting which, Dr. Smith observes, the prolongation of the anterior extremity of the upper lip proves a useful assistant.

Rhinoceros simus, Burch.

Specific Character.—Pale grey brown, tinged with yel[illegible] brown; margins of the ears towards the tips, and tail [illegible] above and below at the extremity clothed with stiff b[illegible] hairs; mouth ox-like; two horns, the anterior one much [illegible] longest; eyes yellowish brown. Length, body and head, [illegible] feet one inch. Height, at the shoulder, 5 feet 7 inches.

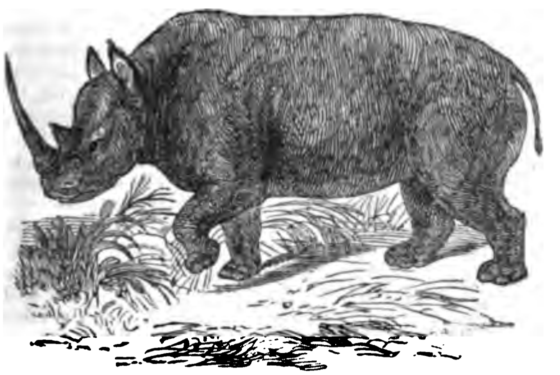
Description.—Pale broccoli-brown, shoulders, buttocks, and belly shaded with brownish purple; hair edging the ears and tip of the tail inferiorly and superiorly black; eyes yellowish brown; horns and hoofs intermediate between broccoli and wood brown; the hoofs darkest.

Figure massive. Head longer, but more delicate in proportion, than in the other African species; face concave, forehead prominent and gibbous. Ears rather long, oval and pointed, their edges towards the tips margined w[illegible] rigid hair. Neck longer in proportion than in the other African species, with three well-marked wrinkles on the nape, two of which continue visible almost to the throat. Shoulders elevated into a convex massive hunch; [illegible] the back slightly undulated. Legs stout, and the joints strongly developed and clumsy. Tail vertically compress[illegible] at the point, and above and below fringed with short [illegible] bristles. Horns situated close to the anterior extremity [illegible] the head, the foremost directly over the point of the n[illegible] and the second immediately behind it; the first very long, tapered to a point, and slightly curved, the concavity backwards; the second is short, conical, and obtuse at the point. Nose truncated, and mouth shaped like that of an ox, the upper lip perfectly square, and without the least indicat[illegible] of a rudimentary proboscis. Nostrils rather small, opening laterally.

Female, coloured like the male: horns, though less powerful, generally longer than his, except the anterior [illegible] (Smith.)

'Mohoohoo, the name of this species among the Bech[illegible]anas,' says Dr. Smith, 'is considered by them to be one [illegible] the original animals of their country, and to have issued from the same cave out of which their own forefathers [illegible]ceeded: in this respect they make a difference between [illegible] and *Keitlca*, with whose origin they do not profess to [illegible] acquainted. Too much attention cannot be paid to the traditions of savages: what in them often appears calculated only to excite ridicule, may, properly considered, be o[illegible] made to furnish the most valuable information. Thus, [illegible] instance, by attending to what has been termed a usel[illegible] tradition, we get to know, not merely that the Bechua[illegible] believe the founders of their own nation and the animal[illegible] their country originally escaped from a large cave, but [illegible] facts of interest touching the geographical distribution [illegible] animals, inasmuch as we may rest satisfied, after be[illegible] aware of the prevalence of the tradition referred to, that [illegible] the animals we find in their country, to whose progenitors the afore-mentioned birth-place is not assigned, have [illegible] migrated thither since the tradition became current. Ev[illegible] portion however of such traditions must not be literally received, else we shall find travellers who may hereafter v[illegible] South Africa propagating errors not less detrimental to the progress of true science than those which were circulated by Kolben, one of the first Cape historians, whose indiscreet credulity led him to relate most extraordinary fictions, *inter alias* one relative to the powers the Rhinoceros exercised over his horns, powers which, had he ever examined [illegible] the manner in which these bodies were connected with the parts around and below them, would have been too clea[illegible] imaginary to have warranted even the greatest lover of the marvellous in believing him.'

Locality, Food, Habits.—Mr. Burchell, who added so much to our knowledge of the zoology of Africa, found, when he was in Latakoo, this species common there; and the natives told Dr. Smith that it was not unfrequently found even farther to the southward. The last-named author however tells us that it has almost ceased to exist, even in the situations where its discoverer met it; and the Doctor observes that this is accounted for by the danger to which it is exposed being now much increased from the general introduction of fire-arms among the Bechuanas. He also remarks that the form of the mouth at once suggests the kind of food upon which the animal probably subsists; and an examination of the contents of the stomach, principally grass, confirmed the inference. 'Localities abounding in grass are therefore the haunts of the Mohoohoo, and to enjoy them throughout the year, he is necessitated to lead a more wandering life than the two species already figured.'



Rhinoceros simus. (Smith.)

We have here collected, we believe, all the species of this interesting genus actually known. But the same author from whom we have so largely quoted, and to whom those interested in African zoology are so largely indebted, indicates others.

'While in the neighbourhood of the tropic,' writes Dr. Smith, 'we heard of two other species of the genus, which exist still farther to the northward; but, unfortunately, could not obtain any very circumstantial evidence concerning them, as the persons who had seen them were only on a visit in the country they inhabit. One of them was stated to approximate to the *Keitloa;* the other was described as very different to any species previously seen by them, and to have only one long horn towards the forehead. Now, though descriptions of objects by such persons are often inaccurate, from the circumstance of their not having been favourably situated for making correct observations, as well as from a deficiency of language calculated to convey the information they actually possess, I have always remarked that even a hasty examination seemed to supply the savage with more accurate notions of the general characters of animals than it did the civilised man, and therefore I do not despair of species such as they mentioned being yet discovered. It is in regard to the species with the single horn that we experience the greatest hesitation in receiving their evidence as credible; and therefore it is agreeable to have it corroborated by the testimony of a man from a very different part of the country, as obtained and published by a missionary of great research who resided a long time in Madagascar.' Dr. Smith then quotes the following passage, previously observing that the individual who furnished Mr. Freeman with the account of the Ndzoo-dzoo was a native of the country northward of the Mozambique; and that if we admit certain portions of the descriptions to be tainted with errors, we can recognise in the remainder the genuine habits of a Rhinoceros, and probably one of the species with which Dr. Smith's informants were slightly acquainted.

'It appears,' observes Mr. Freeman, 'that the Ndzoo-dzoo is by *no means rare* in Makooa. It is about the *size of a horse*, extremely *fleet* and *strong*. It has *one single horn* projecting from its forehead, from twenty-four to thirty inches in length. This is flexible when the animal is asleep; it can be curled like the trunk of the elephant, but becomes perfectly firm and hard when the animal is excited, and especially when pursuing an enemy. Its disposition is extremely *fierce*, and it universally *attacks* man if it sees him. The usual method of escape adopted by the natives is to climb up a dense and high tree, so as to avoid, if possible, being seen. If the animal misses his sight of the fugitive, he immediately gallops off to his haunt, from whence it may be inferred that he is not endowed with the power of a keen scent. Should he however espy his object in the tree, woe to the unfortunate native; he begins to *butt with his horns*, strikes and penetrates the tree, and continues piercing it till it falls, when his victim seldom escapes being gored to death. Unless the tree is of a large girth, he never fails in breaking it down. Having killed his victim, he leaves him without devouring the carcass. The male only is provided with the horn. The female has not anything of the kind.' (*South African Christian Recorder*, vol. i.) This is sufficiently romantic for Sinbad himself; but still, if we strip the description of its fabulous fringes, we see no reason for objecting to Dr. Smith's opinion as to the animal really meant.

With respect to the other Rhinoceros which was said to exhibit a resemblance to the *Keitloa*, Dr. Smith thinks that it may probably be found to belong to a species which has its principal habitat in Northern Africa, a conclusion to which he was led from an examination of a pair of horns in the Museum of the College of Surgeons obtained in Abyssinia by Mr. Salt. These horns differ considerably from those of *Rhinoceros bicornis;* and, in form, approach those of *Rhinoceros Keitloa*. Dr. Smith further observes that another pair of horns, probably of the same species, is preserved, according to Sparrman,* in the cabinet of the Royal Academy of Sciences, the foremost of which is twenty-two inches in length, and the hindmost sixteen: the distance between them is barely two inches. Different again from these and from all Rhinoceroses Dr. Smith had seen, are two contained in the British Museum, and obtained by Major Denham during his journey in North Africa; and Dr. Smith is of opinion that if they do not prove to have belonged to young individuals of *Rhinoceros simus*, they must be referred to a species not yet characterised: they are of a lighter colour than any horns which Dr. Smith had had an opportunity of examining, and, along with a peculiarly corneous aspect, they have a considerable degree of semi-transparency. The horns of *Rhinoceros simus* possess more of this character than any others yet known, which circumstance, together with the fact of which Dr. Smith had been informed by Professsor Owen, namely, that clubs of Rhinoceros horn about three feet in length had been obtained from Western Africa (kingdom of Dahomy), would, in Dr. Smith's opinion, lead to a supposition that either the species discovered by Burchell, or one with certain of its characters, inhabits North Africa.†

'Now,' says Dr. Smith in conclusion, 'though I am not prepared to maintain that the horns of each individual of the same species of Rhinoceros are found to be uniform, as regards size and form, or even that the relative lengths of the first and second horns are constant in different animals, yet from what I have observed in the South African species, I do not think we are justified in believing the horns of the same species to be subject to any great variations in respect to relative length. When the Rhinoceros of Abyssinia shall have been minutely examined, it will probably be found to be distinct from the *Rhinoceros bicornis*, Linn., and be identical with the animal stated, by the natives who communicated with us near the tropic of Capricorn, to be like the *Keitloa*. The other species of which they spoke will possibly be identical with the Ndzoo-dzoo and a nondescript: while the one, from which were obtained the horns referred to as in the British Museum, may prove either a *Rhinoceros simus*, or a third undescribed species.' (*Illustrations of the Zoology of South Africa.*)

There are in the British Museum stuffed specimens of the three African species above recorded: they were purchased at the sale of the African Museum.

In Captain Harris's *Wild Sports of Southern Africa*, the reader will find lively descriptions of the chace and habits of these animals. Their flesh is not unpleasant food. Sparrman had a piece of one of the animals shot by his party broiled immediately: it tasted in a great measure like pork, but, in his opinion, was much coarser.

Fossil Rhinoceroses.

The Fossil Rhinoceroses hitherto discovered may be divided into three groups—1, those with a true or bony *sep-*

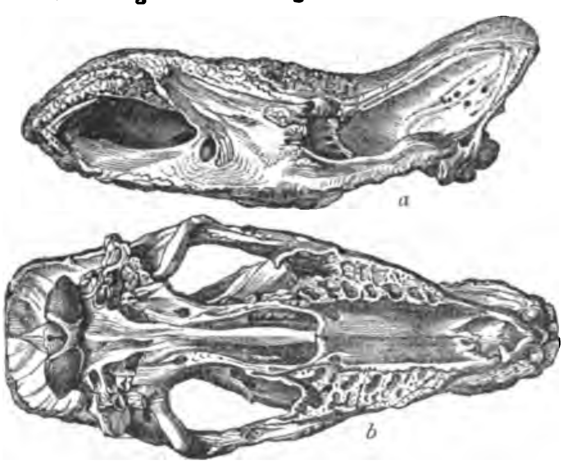
* 'Voyage to the Cape of Good Hope,' 4to., vol. ii., p. 100.

† A Rhinoceros horn wrought for a walking-staff, and so as to make it appear like the horn of 'a *real* unicorn,' was sent to this country by the king of Dahomy; it was, we believe, gorgeously fitted up and sent back to the king.

tum narium; 2, those without a bony septum; and 3, those with incisor teeth.

The greater portion of remains found in Northern and Central Europe and Asia belong to the first group; those found in Italy belong to the second.

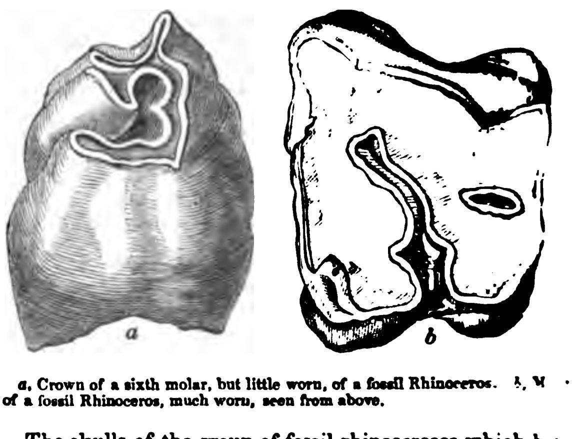
The skulls of the Rhinoceroses belonging to the first group exhibit an essential difference when compared with those of the living species. Those of the former are longer and narrower in proportion; the width between the orbits is less; the bones of the nose are more elongated; the disk on which the anterior horn was seated is an oblong ellipse, whilst in *Rhinoceros bicornis* it is a demisphere. An analogous elongation exists in the place where the second horn was situated, whence Cuvier concludes that the horns of the Rhinoceros with a bony *septum narium* were very much compressed laterally. The same great zoologist remarks that in *Rhinoceros bicornis* or *Africanus* (Cape Rhinoceros) the occipital crest is nearly over the occipital condyles, and the posterior surface of the occiput is nearly perpendicular to the axis of the head. In *Rhinoceros Javanus* this surface is inclined forwards, which renders the distance from the nose to the crest shorter than that from the nose to the condyle in a proportion of 19 to 25; and it is much the same in *Rhinoceros Sumatrensis*. In *Rhinoceros Indicus* this forward inclination is still more remarkable, although the difference of the two lines is less in the proportion of 21 to 25, on account of the extreme height of this occipital surface. In all the fossil skulls, on the contrary, the occipital surface is strongly inclined backwards, and the distance from the nose to the crest much longer than that from the nose to the condyles. It would seem, says Cuvier in continuation, that in some fossil individuals the two horns did not touch each other; but in one from the neighbourhood of Rugby, which Cuvier saw in the Radcliffe Library at Oxford, and of which Mrs. Buckland made a drawing for his work, he is of opinion that the horns touched, for the disks on which they were seated are confounded together in one rugose surface.



Skull of Fossil Rhinoceros. (Cuv.*) *a*, profile: *b*, seen from below.

But, besides the difference of form of the disks, there is, observes Cuvier, on the middle of the anterior one a longitudinal projecting ridge, whilst in *Rhinoceros bicornis* there is a furrow which becomes very deep forwards. Far, too, from having the anterior apophysis of the superior maxillary bone short, and the intermaxillary bones very small, as in *Rhin. bicornis*, the fossil two-horned rhinoceros with the bony septum has those parts extremely long and strong, longer even than in any of the other rhinoceroses; which renders the length of its nasal notch more considerable; in fact, a fourth of the whole length. In the young *Rhin. bicornis* it only makes a sixth, and in the adult a seventh; in the two-horned Sumatran species and the one-horned Javanese species, it is less than a fourth; and in the *Rhinoceros Indicus* rather less than a fifth. This same fossil, remarks Cuvier in continuation, has at the upper border of the incisive bone a prominence, which neither exists in *Rhinoceros bicornis*, nor in *Rhin. Sumatrensis*, nor in *Rhin. Javanus*. It exists only in *Rhin. Indicus*, which differs so much in all other respects from the fossil.

The most important character of the fossil rhinoceros is the form of the nasal bones and their junction with the incisive bones; and it is in this part distinguished not only from the other rhinoceroses, but from all other known animals. The point of the nasal bones, instead of terminating in the air at a certain distance above the incisive bones, descends without thinning off in front of the nasal notches, and, after being divided into three projecting tubercles, is joined by a rather more delicate portion to the spot where the incisive bones unite, and themselves form two other tubercles. All four of these bones are so well soldered together, that only one suture is perceptible, even at an advanced age. The suture which distinguishes the intermaxillary from the maxillary bone is not visible. This solid construction was, observes Cuvier, no doubt destined for the support of the horn, and affords evidence that the fossil rhinoceros had larger and stronger ones than those of the present day, and a consequently increased power of using them. Behind this junction of nasal bones with the incisive bones commences a bony septum, which separates the two nostrils, and which is directed backwards in order to its junction with the *vomer*. In youth this septum appears to have been only cartilaginous; but as the animal advanced in age it became bony, and at last was soldered to the vomer, thus forming one bony continuation. No living rhinoceros yet discovered has this bony septum, the result of which is that the incisive holes are separated from each other, whilst in the living species they are confounded into one vast opening. The length of the nasal notch seems to have been the cause of the backward position of the eye, which had a more posterior situation in this rhinoceros than in the others. The notch of the posterior nostrils is much wider: it does not terminate in a point forwards, but is there nearly squared. The palate is narrower and more elongated in proportion.



a, Crown of a sixth molar, but little worn, of a fossil Rhinoceros. *b*, M... of a fossil Rhinoceros, much worn, seen from above.

The skulls of the group of fossil rhinoceroses which have no bony *septum narium* much resemble that of *Rhinoceros bicornis*. As compared with the cranium of the ordinary fossil rhinoceros which has the bony septum, the cerebral part of the skull is less prolonged and less thrown backwards; the orbit is placed above the fifth molar: the nasal bones terminate in a free point, and are not attached to the intermaxillary bones by a vertical septum; the intermaxillaries are much less prolonged and of a different conformation, offering none of the characters which render the other fossil skulls of this genus so remarkable. But though the skulls without the bony septum approach more to that of the *Rhin. bicornis* than of any other living species, there are notwithstanding several differences. The bones of the nose in the last-mentioned fossils are delicate, straight, and pointed; whilst those of *Rhin. bicornis* are very thick and convex; the intermaxillaries of the fossil are much larger than those of *R. bicornis*, and the zygomatic arch is shorter and more convex towards the top; moreover there is a deeper depression between the part which supports the second horn and that which elevates itself to form the occipital crest.

The lower jaws of the fossil rhinoceroses do not offer less differences between each other than those of the skulls of the respective species. Those of Siberia are remarkable for the narrowed prominence of their anterior part in front of the first molars: at the extremity of this prominence Pallas thought that he detected the remains of the alveoli of incisors. In this character these jaws resemble the one-

* a skull from Siberia, given by Dr Buckland to the Paris Museum.

horned rhinoceros, where the part before the molars is only a little wider. On the contrary, the most common of the fossil lower jaws have their molars brought very near to their point, which is short and not prolonged into a promontory; in which respect they entirely approach *Rhin. bicornis*. They also approached it in all the parts which Cuvier was able to compare, as in the roundness of the lower parts of the branches, the position and size of the holes, and the obliquity of the coronoid apophysis, more than the one-horned rhinoceroses. Differences which our limits forbid us to point out in detail, and which the student will find well followed in the *Ossemens Fossiles*, exist in the rest of the skeletons of the fossil species as compared with the living ones, and even with each other.

The fossil rhinoceroses furnished with incisor teeth were much smaller than any known species, living or fossil.

The following fossil species have been recorded:—*Rhinoceros tichorinus*, Cuv.; *Rhinoceros incisivus*, Cuv.; *Rhinoceros leptorhinus*, Cuv.; *Rhinoceros minutus*, Cuv.; *Rhinoceros elatus*, Croiz. and Job.; *Rhinoceros pachygnathus*, Cuv.; *Rhinoceros hypselorhinus*, Kaup.; *Rhinoceros Goldfussii*, Kaup.; *Rhinoceros leptodon*, Kaup.*

Geological Position.—Remains of this genus occur in the tertiary series of beds (Miocene and Pliocene periods of Lyell); in the strata of the last-named period they are most abundant. They are extensively found in the gravel, the bone caverns, and osseous breccia. In 'Reliquiæ Diluvianæ,' Dr. Buckland states that the facts developed in the cave at Kirkdale demonstrate that there was a long succession of years in which the Elephant, Rhinoceros, and Hippopotamus had been the prey of Hyænas, which, like themselves, inhabited England in the period immediately preceding the formation of the diluvial gravel. 'If they inhabited this country,' says Dr. Buckland, in continuation, 'it follows as a corollary, that they also inhabited all those other regions of the northern hemisphere in which similar bones have been found under precisely the same circumstances, not mineralized, but simply in the state of grave bones imbedded in loam, or clay, or gravel, over great part of northern Europe, as well as North America and Siberia.' The entire Rhinoceros found in the frozen soil at Wiluji, or Villioui, in Siberia, recorded by Pallas, was a most striking discovery, and, followed as it was by the detection of an Elephant in a mass of ice on the shores of the North Sea [Elephant, vol. ix., p. 352], aroused the minds of men to a consideration of the causes which might have produced such effects. Dr. Buckland thus comments on the state of the climate in which these extinct species may have lived:—'It is the opinion of Cuvier, on the one hand, that as some of the fossil animals differ from existing species of the genera to which they belong, it is probable that they had a constitution adapted to endure the rigours of a northern winter; and this opinion derives support from the Siberian elephant's carcass, discovered with all its flesh entire, in the ice of Tungusia, and its skin partially covered by long hair and wool; and from the hairy Rhinoceros found in 1771, in the same country, in the frozen gravel of Villioui, having its flesh and skin still perfect, and of which the head and feet are now preserved at St. Petersburgh, together with the skeleton of the elephant above alluded to, and a large quantity of its wool; to which Cuvier adds the further fact, that there are genera of existing animals, e.g. the fox tribe, which have species adapted to the extremes both of polar and tropical climates. On the other hand it is contended that the abundant occurrence of fossil crocodiles and tortoises, and of vegetables and shells (e.g. the *Nautilus*) nearly allied in structure and character to those which are now peculiar to hot climates in the secondary strata, as well as in the diluvium of high northern latitudes, renders it more probable that the climate was warm in which these animals lived and died, than that any change of constitution and habit should have taken place in so many animal and vegetable genera, the existing members of which are rarely found, except in the warmer regions of the present earth. To this argument I would add a still greater objection, arising from the difficulty of maintaining such animals as those we are considering amid the rigours of a polar winter; and this difficulty cannot be solved by supposing them to have migrated periodically, like the Musk-Ox and Rein-Deer of Melville Island; for in the case of Crocodiles and Tortoises extensive emigration is almost impossible, and not less so to such an unwieldy animal as the Hippopotamus when out of the water. It is equally difficult to imagine that they could have passed their winters in lakes and rivers frozen up with ice; and though the Elephant and Rhinoceros, if clothed in wool, may have fed themselves on branches of trees and brushwood during the extreme severities of winter, still I see not how even these were to be obtained in the frozen regions of Siberia, which at present produce little more than moss and lichens, which during great part of the year are buried under impenetrable ice and snow; yet it is in these regions of extreme cold, on the utmost verge of the now habitable world, that the bones of elephants are found occasionally crowded in heaps along the shores of the icy sea from Archangel to Behring's Straits, forming whole islands composed of bones and mud at the mouth of the Lena, and encased in icebergs, from which they are melted out by the solar heat of their short summer, along the coast of Tungusia, in sufficient numbers to form an important article of commerce.' Dr. Buckland then observes that he is in the work quoted ('Reliquiæ Diluvianæ') concerned only to establish two important facts;—first, that there has been a recent and general* inundation of the globe; and, secondly, that the animals whose remains are found interred in the wreck of that inundation were natives of high north latitudes, and not drifted to their present place from equatorial regions by the waters that caused their destruction. 'One thing however is nearly certain,' adds Dr. Buckland, 'viz. that if any change of climate has taken place, it took place suddenly; for how otherwise could the elephant's carcass found entire in ice at the mouth of the Lena have been preserved from putrefaction till it was frozen up with the waters of the then existing ocean? Nor is it less probable that this change was contemporaneous with and produced by the same cause which brought on the inundation. What this cause was, whether a change in the earth's axis, or the near approach of a comet, or any other cause or combination of causes purely astronomical, is a question the discussion of which is foreign to the object of this memoir.'

The distribution over the earth's surface of the remains of this genus is very wide. Almost every bone-cavern in England, Germany, and France contained them. They occur in the Eppelsheim sand, in the bone breccia at Nice, and at Gibraltar. Mr. Crawfurd collected them on the left bank of the Irawadi, 230 miles below Ava; and Captain Cautley found them in great abundance in the Sewalik mountains, at the southern foot of the Himalayas. RHI'NOPHIS, Wagler's name for a genus of Serpents with a pointed conical muzzle, the tip of the tail enveloped in an oval horny shield, and the eyes hidden. Mr. Swainson arranges it as a subgenus of *Typhlops*, in the family *Amphisbænidæ*.

RHINOPI'RUS, Merrem's name for a genus of Serpents, *Erpeton* of Lacépède. [Erpeton.]

RHIO is a Dutch colony, established in 1817, on the island of Bintang, which lies opposite Cape Romania, one of the promontories with which the Malay peninsula terminates on the south. The island of Bintang is a little larger than that of Singapore, and contains about 300 square miles. It is however more fertile, and produces much terra japonica; above 4000 tons are annually exported. Much pepper is also grown. After Java, Malacca, and the other Dutch colonies had been restored to the Dutch, the Dutch government intended to make themselves masters of the commerce of the Indian Archipelago, and with that view took possession of the town of Rhio, where they built a fortress; but the foundation of the town of Singapore and the rapid growth of that British colony has frustrated their design: yet Rhio is a thriving place. It is visited by the Bughis and other Malay vessels from the adjacent islands, and by the Siamese, though they prefer going to Singapore, where their commodities fetch a better price and are more easily saleable. The town and fortress of Rhio are built at the entrance of a wide inlet, called the bay of Tanjong Pinang. The harbour is good and safe, but at its entrance there are many small rocky islands, which render the navi-

RHIPIDU'RA. [MUSCICAPIDÆ, vol. xvii., p. 13.]

RHIZANTHS. [RAFFLESIA.]

RHIZOMORPHA, a singular genus of fungi, having altogether the appearance of the root of a tree. The species are found in damp cellars, old walls, mines, and other subterranean places, where they sometimes acquire a phosphorescent state, which renders them exceedingly curious objects. Nothing is at present known of their mode of reproduction or origin; but it is thought that they spring out of decaying wood buried in the ground. The genus Rhizomorpha is not included in Hooker's 'English Flora,' but it is mentioned by Mr. Berkley, who wrote the mycological department of that work, as a fungous production, originating in tan-pits. Several species are mentioned by authors, of which R. medullaris is the most common. This is so like the root of a tree divided into numerous fibres, that it is probably often mistaken for it. Independently however of its cellular organization, so different from that of wood, it may always be known by its musty smell.

RHIZO'PHORA, a genus of plants which gives its name to the natural family of Rhizophoreæ, or the Mangrove tribe, the plants of which are remarkable for their seeds germinating even while attached to the branches, and also for the numerous adventitious root-like projections which serve as supports for the stem. The common Mangrove and also others of the genus are found all along the shores of the tropics, both in the new and old world, rooting in the mud, and forming dense forests even at the verge of the ocean, and below high-water mark; hence, on the retiring of the tide, the stems may often be seen covered with oysters and other shell-fish. The genus may be briefly characterised as having—a four-parted adherent calyx. Petals four, the margins each with a long row of double hairs. Stamens twice as many as the petals. Ovary 2-celled, with 2 ovules in each cell. Style short. Stigma 2-toothed. Fruit oblong, crowned with the persistent segments of the calyx, at length perforated at the apex by the radicle of the germinating embryo. Trees with entire leaves. Inflorescence axillary. The wood of several species is hard and durable, and the bark astringent.

R. Mangle, the common or black Mangrove, is found abundant on the shores of the ocean, and within the delta of the Ganges, where it grows to a considerable size. The seed of this species, which is from one to two feet long, very quickly gives rise to a young tree, and, as mentioned by Browne, in his 'History of Jamaica,' if the apex from whence the root issues be stuck only a little way in the mud, the leaves quickly unfold at the opposite end. The wood is dark-red, hard, and durable, and the bark is used for tanning leather.

R. Candel, Red Mangrove, or *Paletuvier*.—The branches of this species, though they bend downwards, do not take root in the ground. The wood is heavy, of a deep-red, and takes a fine polish. The bark is used in dyeing red, is astringent, and used in the West Indies for the cure of fevers, as well as of the bites of venomous insects.

R. gymnorhiza grows to a considerable size where the spring-tides rise over it, as in the delta of the Ganges. The wood is yellow, hard, and durable; has a sulphurous smell, and burns with a vivid light; is chiefly used by the natives for fire-wood and for making posts for constructing their houses. The pith of the wood, boiled in palm wine or with fish is used as food.

RHODE ISLAND (Island). [RHODE ISLAND (State).]

RHODE ISLAND, one of the United States of North America, is bounded on the north and east by Massachusetts, on the west by Connecticut, and on the south by the Atlantic. It extends from 41° 18′ to 42° N. lat. and from 71° 6′ to 71° 58′ W. long., Block Island not included. The largest part of the state lies to the west and north-west of Narraganset Bay, and comprehends about 900 square miles; a small portion lies to the east of Narraganset Bay; and the rest is composed of the islands of Rhode Island, Connecticut Island, Prudence Island, Patience Island, Hope Island, Hog Island, Dyer's Island, and Block Island, all of which are in Narraganset Bay, except the last, which is in the Atlantic. The whole area of the state is estimated at 1350 square miles, which is about the area of the English county of Shropshire. It is the smallest state in the Union, though there are others which have a less number of inhabitants. The population, in 1790, was 69,110; in 1800, 69,122; in 1810, 77,031; in 1820, 83,059; and in 1830, 97,199, which is 72 to a square mile, being in density of population inferior only to Massachusetts, which by the same census has 81 to a square mile. The number of slaves included in the population was 952 in 1790; 831 in 1800; 103 in 1810; 48 in 1820; and 17 in 1830.

The island of Rhode Island, which gives name to the state, is the largest of the islands which belong to it. The central part of it is in 41° 32′ N. lat. and 71° 15′ W. long. Its length is about 15 miles from north to south, with an average breadth of about 3½ miles. This island is the most fertile part of the state; the soil is suitable either for tillage or grazing, and is well cultivated; and the climate is so temperate and wholesome, that the island is a place of resort for the inhabitants of the southern and central states in the summer months, and for invalids at all seasons.

Narraganset Bay, which intersects a large portion of the state, is about 28 miles long from Point Judith, on the south, to Bullock's Point, 5 miles below Providence, on the north. The entrance extends from Point Judith on the west to Seekonnet Rocks on the east. The average breadth of the bay is about 10 miles. It forms a safe road during the north-west storms, is navigable in all seasons, contains several excellent harbours, and has many points suitable for defence, which have been strongly fortified.

The surface of the continental part of Rhode Island is generally level, but is hilly and rocky in some parts, chiefly to the north-west. The principal rivers are the Seekonk, the Pawtucket, the Pawtuxet, and the Pawcatuck, all which have a short course. The soil is generally thin, and for the most part better fitted for pasturage than for the plough. Cattle and sheep are raised in great numbers on the islands and on the coasts of Narraganset Bay. Wheat, oats, barley, and rye, and also many kinds of fruit, are cultivated to a considerable extent, and the rivers and bay supply plenty of fish. There are mines which afford abundance of iron-ore, and small quantities of copper-ore are obtained. Limestone is abundant, and there is a mine of anthracite coal in the northern part of the island of Rhode Island.

The exports of Rhode Island consist principally of cattle, horses, poultry, fish, beef, cheese, butter, lumber, and flaxseed, cotton and linen manufactures, and iron manufactures. The manufactures are in a very flourishing condition, and are rapidly increasing. Providence is the chief point of manufacturing and commercial industry. The imports consist for the most part of the produce of the West Indies and the manufactures of Europe. The exports in the year ending September 30, 1839, were of the value of 185,234 dollars, of which 175,808 were for domestic produce, and 9426 for foreign produce. The imports were of the value of 612,057 dollars, of which 610,431 were in American vessels, and 1626 in foreign vessels. The shipping, on the 30th of September, 1839, was estimated at 44,572 tons.

There is a railroad from Providence to Stonington, the length of which is 47 miles. The total length of canals in Rhode Island is 38 miles.

The General Assembly of Rhode Island meets four times a-year. The senate is composed of a governor, lieutenant-governor, and ten senators. The governor is elected half-yearly, and has a salary of 400 dollars. The lieutenant-governor, also elected half-yearly, has a salary of 200 dollars. The House of Representatives consists of 72 members, elected half-yearly, in April and August.

There is a supreme court, and there is also a court of common pleas for each of the five counties into which the state is divided. The supreme court consists of a chief-justice, with a salary of 650 dollars, and two associate justices, with salaries of 550 dollars each. All the judges are appointed annually by the General Assembly. The district court meets in February and August at Providence, and in May and October at Newport. The circuit court is held at Providence in November, and at Newport in June.

Rhode Island has no state debt. In December, 1839 there were 62 banks, with a capital of 9,860,500 dollars, specie to the amount of 537,895 dollars, and a circulation of 1,719,230 dollars.

The state pays 10,000 dollars a year for the support of free schools, which is divided among the different towns according to their population. Brown University is the only one in the state, but there are ten or twelve academies, and about 300 elementary schools not supported by the state. In 1834 there were 16 newspapers published in the state – 9 at Providence, 3 weekly at Newport, 1 weekly at Bristol, 1 weekly at Warren, 1 weekly at Pawtucket, and 1 weekly at Woonsocket Falls.

Of the religious denominations, which are said to amount to about 100, the Baptists are the most numerous; then follow the Methodists, Congregationalists, Unitarians, Sabbatarians, Six-Principle Baptists, Quakers, &c.

Rhode Island has two capitals, Providence and Newport.

Providence is a corporate city, and considerably the largest and most flourishing town in the state, in 41° 51′ N. lat. and 71° 26′ W. long. It is situated at the head of Narraganset Bay, at the top of an inlet which is called Providence River, but which is only an arm of the bay reaching to the mouth of the Seekonk river. The town is built on both sides of the Providence River, and the two parts are connected by bridges, the longest of which is 90 feet. Vessels of 900 tons burthen can come up to the wharfs. Most of the houses are of wood, and painted white, but there are several of granite and brick. The inhabitants amount to upwards of 20,000. The chief public buildings are—the State House, of brick; the Arcade, which is a magnificent building of Doric architecture, the body of stone, and the two fronts and the columns of granite; the two halls of Brown University, of brick; the Dexter Asylum, of brick, for the poor of Providence; the Friends' Boarding-school, of brick, with a basement of granite; and some of the churches are handsome buildings. Brown University, originally founded at Warren in 1764, but removed to Providence in 1770, is chiefly under the direction of the Baptists. It has 9 instructors, 1390 alumni, 474 ministers, 177 students, and a library of 14,000 volumes. There are several public schools, and three or four libraries belonging to literary institutions. In 1834 there were 9 newspapers published at Providence, 3 daily, 2 semiweekly, and 4 weekly; 1 literary journal, weekly; and 4 monthly periodicals.

Providence is a place of great manufacturing industry. There are large cotton manufactories, worked both by steam and by water-power; extensive bleaching establishments; dye-houses; iron-foundries; manufactories for making cotton-machinery; steam-engines and steam-boilers; brass-foundries; establishments for working in tin, sheet-iron, copper, brass, &c.; numerous jewellers' and goldsmiths' shops; a large glass-house; besides hat, soap, and several smaller manufactories.

In 1831 the imports into Providence amounted to 157,717 dollars; the exports to 329,634 dollars. The shipping on the 31st of December, 1832, was estimated at 1[illegible],136 tons. There were 4 insurance companies and 15 banks, besides a branch of the United States Bank; and also a savings' bank. The Blackstone canal, which extends from Providence to Worcester in Massachusetts, was completed in 1828. It is 45 miles long, and is navigated by about 30 boats of from 25 to 30 tons each. Providence is 1[illegible]0 miles north-east from New York, 40 miles south-south-west from Boston, 30 north from Newport. Passengers from New York are brought by steam-boats to Providence on their way to Boston.

Newport, the town next in importance to Providence, is situated at the south end of the island of Rhode Island, in 41° 29′ N. lat. and 71° 21′ E. long. It has between 8000 and 9000 inhabitants. The situation is very beautiful, and it has a fine harbour.

The other towns of most importance are:—Scituate, with [illegible]850 inhabitants; Warwick, with 5500; Smithfield, with [illegible]000; Coventry, with 3850; New Providence, with 3500; South Kingston, with 3700; North Kingston, with 3000; and Bristol, with 3000. Pawtucket, a large village not far from Providence, and connected with that city by one of the finest roads in the United States, has some considerable cotton manufactures.

The circumstances under which Rhode Island was founded, as connected with the opinions and conduct of its founder, Roger Williams, are sufficiently curious and interesting to merit a short detail.

Roger Williams was a native of Wales, and born in 1598. He was educated at the university of Oxford, and admitted to orders in the church of England, but having embraced the opinions of the Puritans, the severity of the laws against non-conformists occasioned him to embark for North America, where he arrived, with his wife, on the 5th of February, 1631. The principles which Williams began to preach at Boston were those of unlimited religious toleration, extended not merely to every sect of Christians, but to Jews, Mohammedans, heathens, and infidels. This extent of toleration was not approved by the New England churches, and Williams having been chosen by the people of Salem as assistant-teacher, the court of Boston 'marvelled' at their precipitancy, and they were required to 'forbear.' They did forbear, and Williams withdrew to Plymouth, where he was also engaged as assistant-teacher, and remained two years. In 1633 he returned to Salem. He had written an essay in which he contended that the patent of the king of England could not rightfully dispose of the lands of the natives without their consent. For this he was summoned on the 24th of January, 1634, before the court of Massachusetts, when, having explained the purport of the offensive manuscript, and consented that it should be burnt, the court declared that 'the matters were not so evil as at first they seemed.'

The magistrates of Massachusetts required every man to attend public worship. Williams reprobated the law (35 Eliz., c. 1) by which they enforced it, and this was another ground of offence to the magistrates. The English government had become extremely jealous of the proceedings in Massachusetts, and with the view of preparing for resistance, the Freeman's Oath, which required every freeman to swear allegiance not to King Charles but to Massachusetts, was administered by the magistrates. Williams denied the right of a cumpulsory imposition of an oath; and when summoned before the court, March 30, 1635, he maintained his opinion, and 'the government was forced to desist from that proceeding.'

Soon afterwards the church of Salem chose him for their teacher, and Williams having asserted that 'the civil magistrate might not intermeddle to stop a church even from apostacy and heresy,' the magistrates blamed the people of Salem for their choice of a teacher, and as a punishment withheld from them a tract of land to which they had a claim. Williams now, in conjunction with his church, wrote 'letters of admonition unto all the churches whereof any of the magistrates were members, that they might admonish the magistrates of their injustice.' This was held to be little less than treason, and the next general court disfranchised Salem till an apology for the letter should be made. The town and the church submitted. In October, 1635, he was summoned before the general court, and required to renounce the offensive opinions; but he maintained 'the rocky strength of his grounds.' The general court then pronounced a sentence of banishment against him, but as the winter was near, he obtained permission to remain till spring. And now the people of Salem could no longer be restrained; they thronged to his house to hear him; and as many were 'much taken with the apprehension of his godliness,' and there was evident danger of the infection of his opinions spreading very widely, it was resolved to send him to England in a ship then ready to sail. A warrant was sent requiring him to come to Boston to embark. He refused to come. A pinnace was sent to bring him, but he had fled. It was the depth of winter (January, 1636). 'For fourteen weeks he was sorely tossed in a bitter season, not knowing what bread or bed did mean.' He wandered towards Narraganset Bay, and was welcomed by the Indians, whose language he had learned. In June, 1636, with five companions, he founded his little settlement at the mouth of the Seekonk river. He named the place 'Providence.' 'I desired,' he said, 'it might be for a shelter for persons distressed for conscience.' On the 24th of March, 1638, the chiefs of the Narragansetts, to whom the territory belonged, presented him with an Indian deed, which made him the entire owner of a large domain; but he reserved none of it for himself; 'he gave away his lands and other estate to them that he thought were most in want, till he gave away all.'

This was the foundation of the state of Rhode Island, which was then called *Providence Plantations*. A sect of violent Antinomian Calvinists had sprung up in Massachusetts, who became offensive to the government, and its leaders were sentenced to banishment. They were welcomed by Roger Williams, and through his influence and that of Sir Henry Vane, who was then residing in Massachusetts, they obtained from the Narragansetts (March 24, 1638) the island of Rhode Island; and the colony of *Rhode Island* was thus founded.

The people of Providence Plantations and Rhode Island, excluded from the colonial union, had no chance of maintaining a separate existence without the powerful protection of the mother country; and, in 1643, Roger Williams was chosen to conduct a mission to England for the purpose of obtaining a charter. The affairs of the American colonies were at this time under the control of the earl of Warwick as governor-in-chief, assisted by a council of five peers and twelve commoners. Sir Henry Vane was one of these commoners; and chiefly through his influence a charter was granted, dated March 14, 1644, by which the two colonies were incorporated under the title of *Rhode Island.* When Williams reached Seekonk on his return, the river was covered with canoes to welcome him. But the danger was not over. In April, 1651, a commission was granted to Coddington for governing the islands of Narraganset Bay, and the two small colonies were again exposed to the risk of being dismembered and parcelled out between the adjacent governments. Williams, in conjunction with John Clarke, again returned to England; and in Oct., 1652, Coddington's commission was vacated, and the charter of Rhode Island confirmed. Williams returned in 1654; but Clarke remained, and obtained another charter in 1663, which still continues to be the constitution of Rhode Island. Williams died in April, 1683, at Providence. He is the author of 'A Key into the Language of New England,' London, 1643, 8vo. His other writings were chiefly controversial, in reply to Cotton and George Fox. In answer to a work of the latter, he published his 'George Foxe digged out of his Burrowes.'

(Bancroft's *History of the United States*, vol. i.; *Encyclopædia Americana; American Almanac*, 1835, 1837, 1841.)

RHODES, an island off the coast of Caria in Asia Minor, opposite to Cape Volpe, between the gulfs of Syme and Macri. The harbour of the city of Rhodes is in 28° 12′ E. long. and 36° 26′ N. lat., according to Niebuhr. Rhodes was inhabited in very early times, and the Greek poets have shown more than their usual ingenuity in inventing fables to account for the origin of its first settlers. Rhodes was called Ophiusa, Æthræa, Trinacria, and by other names, which are enumerated by Pliny (v. 31). Pindar, in one of the most beautiful of the Olympian odes, records the myth that it was raised by Apollo from the waves, like Delos. The earliest of its inhabitants were called Telchines, under which name it is probable that the Phœnicians, as the first introducers of civilization, are alluded to. It was successively occupied by the Heliadæ, Danaides, and other mythological personages.

Passing from these traditions, we recognise something of historical truth in the story of Tlepolemus, the son of Hercules, who is said to have colonised Rhodes after his father's death. He is named in Homer among those who led forces to the Trojan war from Rhodes. The poet, in the same passage, makes mention of the three antient towns of Rhodes, Lindus, Camirus, and Ialysus; and of a triple division of the island into districts attached to them.

A second migration from Greece to Rhodes, led by the Argive Althaemenes, took place about the same time as the great movement of the Ionians in the same direction, the date of which is fixed by Clinton (*Fasti Hellenici*) to 988 B.C. The three towns already mentioned, with the neighbouring continental cities, Cos, Halicarnassus, and Cnidus, formed a confederacy, which, after the exclusion of Halicarnassus, was called the Doric Pentapolis. Between this period and the first Olympiad, 776 B.C., the Rhodians had already shown that love of commercial and maritime enterprise for which they were afterwards distinguished, and had made voyages to distant countries. They founded the colonies of Rhode in Iberia, Gela in Sicily, Parthenope among the Osci in Italy; and nearer home, Corydalla and Phaselis in Lycia, and Soli in Cilicia.

About 660 B.C., the antient kingly form of government which prevailed in the island, as in other Dorian states, was abolished, and magistrates, called prytanes, probably substituted. Such offices were filled by the family of the Eratidæ at Ialysus, who were originally kings of that city. In the seventh Olympian ode, Pindar celebrates the Olympic victories of Diagoras, one of this race, speaks of the influence of his kinsmen in Ialysus, and cautions the citizens of that place against innovations. This was about 464 B.C., when it is probable that the Athenians, who were extending their sway over the Archipelago, had already interfered with the internal government of the island.

During the Persian and Peloponnesian wars there is very little mention of Rhodes. It must have declined, like Miletus and various maritime powers on the coast of Asia Minor, and most likely from the same causes. In the course of the latter war, the alternate subjection of the Rhodians to the Athenians and Lacedæmonians produced a corresponding change in the constitutions of their cities from oligarchy by turns to democracy; and this led to internal disorders, and to the expulsion of the two representatives of the Eratidæ. One of them however, Dorieus, who was recalled by Spartan influence, succeeded in replacing the government in the hands of the nobles. In 408 B.C., the city of Rhodes was founded, by collecting into one spot the inhabitants of Lindus, Ialysus, and Camirus; and from this time the history of the city is identical with the history of the island.

In 357 Rhodes reverted for a short time to the dominion of Athens, against which state it soon after formed a league with Cos, Chios, and Byzantium. The Social War ensued, and was terminated in 355, on the condition of the future independence of the Rhodians. No sooner had they succeeded in shaking off their distant enemy, than they experienced the dangerous influence of a near neighbour, Mausolus, king of Caria, who, in consequence of the assistance which he had afforded them in their war with Athens, obtained great power in the island, and joined with the oligarchy in oppressing the rest of the citizens. After his death, his wife Artemisia, having by a stratagem obtained possession of the Rhodian fleet, deprived Rhodes for a time of its liberty. A Carian garrison was placed in the Acropolis, and it is probable that to this period may be referred the excesses of Hegesilochus and his companions, who are described in a fragment of Theopompus quoted by Athenæus (lib. x., p. 444, Casaub.) as the establishers of a corrupt and debauched oligarchy.

These internal disorders led to a mixed form of government, in which, as far as we can gather from writers of antiquity, the elements of democracy and aristocracy were balanced.

Two chief magistrates, called prytanes, vested with great powers, and taking precedence of each other by turns for the space of six months, were appointed every year. There was a senate, all the members of which had a vote in the public assembly, and sat in alternate months in the senate and among the people. In the public assemblies the people voted by show of hands. According to Strabo, great care was taken of the poor; they were provided with corn, and maintained at the expense of the rich, who were subject to leiturgiæ for that purpose. The superintendence of the marine and other matters was managed on oligarchical principles: the good effects of a constitution so modified were shown by the cessation of internal disorders in the city from this time.

After the death of Artemisia, we find the Rhodians in alliance with Athens, sending assistance to Byzantium against Philip of Macedon. Idrieus, king of Caria, seems to have claimed some sort of supremacy over them.

They submitted, like the rest of Greece, to Alexander the Great, but expelled his troops from their city after his death. At this period they attached themselves very strongly to Ptolemy Soter, and received great benefits from Egyptian commerce. When they refused to assist Antigonus in his war against that prince, his son Demetrius, surnamed Poliorcetes, was sent against them; and the first of the memorable sieges to which Rhodes has at various times been subjected commenced. The courage of the defenders was only equalled by the ingenuity with which the assailants applied every engine of assault which the mechanical knowledge of that age could suggest.

After many struggles the Rhodians succeeded in repulsing this formidable enemy (B.C. 303), and made peace on the condition that they should be the allies of Demetrius against every one but Ptolemy. From this epoch we may trace the rapid ascendency of Rhodes. The old maritime powers of Greece having fallen to decay, the supremacy of the seas fell to the share of this island, and great commercial success and refinement in the culture of art were the immediate results. The celebrated colossal figure of the sun was made at this time from the sum raised by the sale of the war-engines employed against the city in the siege, and generously presented by Demetrius, after peace was made, as a tribute to Rhodian valour. The statue, of which Pliny (lib. 34, c. 7) has left an account, was begun by Chares, a pupil of Lysippus, and completed by Laches, both of Lindus. It was made of brass; the height is said to have been 70 cubits; the thumb was so large that few men could span it: twelve years were employed in making it. The notion that its legs rested one on each side of the harbour at Rhodes does not seem to be supported by any good authority, and modern travellers do not agree as to its site. After it had stood for 56 years, it was thrown down by an earthquake by which the buildings of the city suffered very much. Such was the commercial importance of Rhodes, that on this occasion the great princes of the day vied with each other in the munificence of their presents to repair its losses. Hiero king of Sicily, Ptolemy Euergetes, Antigonus Doson king of Macedon, Seleucus III., and the various inferior powers of Asia Minor came forward with ready zeal to serve a city whose fleets protected the seas against pirates and extended mercantile communication. The Rhodians (219 B.C.), assisted by Prusias, king of Bithynia, compelled the Byzantines to remit the duty which they had been in the habit of exacting from ships that passed through the Bosporus, and shortly afterwards protected Sinope against Mithridates IV., king of Pontus.

A new epoch in the history of this people is marked by the first direct mention of the interference of the Romans in their affairs. Rhodes joined Attalus, king of Pergamus, in his war against Philip III., king of Macedon. The Romans threw their weight into the scale against Philip, and entered into an alliance with the two powers that were attacking him. After his defeat at Cynoscephalae, B.C. 197, the Rhodians joined Rome in a war with Antiochus, in which their navy was of great service. In gratitude to their new allies, the Romans gave them Caria and Lycia. From this time the prosperity of the city began to decline. Her recently acquired continental possessions tested her sway, and in their struggles appealing from time to time to the Roman senate, gave that body an opportunity of practising their usual policy of interference. During the war that followed with Perseus, king of Macedon, the Rhodians, in their internal factions mistaking their true interests, became the allies of that prince, but full of consternation at the news of his speedy defeat, 168 B.C., they submitted to Rome, and gave up their territory in Asia Minor. Their revenue was curtailed, and they experienced other marks of the displeasure of the senate. From this time till the Mithridatic war (88 B.C.), we hear little of them. They then gave important aid to the Romans by sea, and were in consequence attacked by the king of Pontus with a great armament, which they defeated. In requital for their fidelity, Sulla at the close of the war confirmed their liberty. During the contest between Pompey and Julius Caesar they took the part of the former, but abandoned him after the battle of Pharsalia. They attached themselves to Caesar from this time, and after his death, still supporting his partizans, drew down upon themselves the anger of Cassius, who seized the city, and severely punished the inhabitants, by taking away their ships and fining them heavily.

After the battle of Philippi, Rhodes was restored to freedom by Antonius, in the enjoyment of which its inhabitants remained till the time of Claudius, who, in consequence of the frequent revolts, withdrew some of their privileges, which however he afterwards restored. Finally, Vespasian incorporated this island in a Provincia Insularum, of which it was probably the seat of government. Here the antient history of Rhodes ceases.

In the brief sketch which we have here attempted, many interesting particulars have been necessarily omitted relating to the foreign policy, the commerce, the government, arts, manners, literature, and religion of the Rhodians, and characteristic at once of the Dorian race, of a maritime and trading people, and of the influence of an Asiatic climate on the physical and intellectual condition of the Greeks. The code of laws relating to their navy, adopted afterwards by other maritime states (see *Dig.*, 14, tit. 2, 'De Lege Rhodia'), the powers vested in the several branches of their executive administration, their sumptuary statutes, and regulations to protect their poor, all claim especial attention from the student of antient history. In their most flourishing age, their city, like Alexandria at the same period, was the place of resort of learned men from all countries, and a very similar style of literature sprung up in both places. We cannot indeed expect to find among the writers of these times the freshness of fancy and originality of thought of earlier Greece, but the spirit of research and critical inquiry was awakened, and great progress made in mathematics and other sciences.

Rhodes is particularly distinguished as the parent of a new style of oratory, which the antients considered of a mixed or Graeco-Asiatic type. Such too was the character of their contemporary art, which seems to have delighted in executing gigantic and imposing conceptions. Besides the celebrated Colossus, three thousand other statues adorned the city, and of these 100, according to Pliny, were on such a scale that the presence of any one of them would have been sufficient to ennoble any other spot. The architecture of Rhodes was of the same stately character; the ground on which it stood sloped gradually to the sea, like the interior of an antient theatre. The plan, designed by the same architect who built the Piraeus at Athens, was perfectly symmetrical, so much, Aristides remarks in his 'Rhodian Oration,' as if it had been one house. The streets were wide and of unbroken length, and the fortifications, strengthened at intervals with lofty towers, did not appear, as in other cities, detached from the buildings which they enclosed, but by their boldness and decision of outline heightened the unity and connection of the groups of architecture within. The temples were full of the finest paintings, the works of Protogenes, Zeuxis, and other artists of the school of Rhodes. The celebrated picture of Ialysus, by Protogenes, which was afterwards brought to Rome, was the object of universal admiration. The coins of Rhodes are numerous and of good workmanship. The most usual type is a radiated head of the sun, and on the reverse a flower which has been called that of the pomegranate, though on some of the coins it rather more resembles the rose, and thus may be considered as a type allusive to the name of the island, the Greek word *rhodon* (ῥόδον) signifying a rose. Spanheim in his great work on coins has given a long dissertation on the subject. Other deities that occur on the obverses on the coins of Rhodes are Jupiter, Neptune, Bacchus, and Serapis. The head of Medusa also is met with. The coins struck under the Roman emperors are given as late as the time of Commodus in Mionnet ('Description des Médailles Antiques: Rhodes'). The word ΤΑΜΙΑ occurs on some of the *autonomous* coins; this is an interesting fact, as we have notices from other sources of the existence of such a magistrate at Rhodes.

A few scanty notices of Rhodes may be collected from the historians of the Lower Empire. After having been made by Vespasian into the head of a province, it afterwards formed part of the Thema of Cibyra, as appears from the work of Constantine Porphyrogennetos on the Themata.

In the reign of Heraclius (A.D. 616), Rhodes is mentioned among the conquests of Chosroo, king of Persia, but reverted to the dominion of the Greek emperors shortly afterwards. (Gibbon, vol. v., p. 626, Lond., ed. 1828.) In the caliphate of Othman, A.D. 651, it was taken by Moawiyah, one of his generals, and the fragments of the Colossus, which had been lying on the ground ever since its fall, were collected by the Saracens, and sold to a Jewish merchant of Edessa, who is said to have laden 900 camels with the weight of metal.

In the year 716 Theodosius III. was proclaimed emperor of the Greeks, in consequence of the revolt of troops in Rhodes against his predecessor Anastasius. The island had been probably abandoned by the Saracens before this date. We find it again forming a part of the Greek empire at the taking of Constantinople by the Latins, A.D. 1204, and in the general partition which then followed it was seized by some adventurer, whose name Nicetas Choniata, speaking of the circumstance, does not give.

Rhodes was not long after restored to the dominion of the Greeks, by John Ducas. At the commencement of the fourteenth century it seems to have been occupied by revolted Greeks and Mussulman corsairs, when (A.D. 1310) Fulke de Villaret, grand-master of the knights of St. John, carried into execution the design of his brother and predecessor Guillaume de Villaret, and made himself master of the island, which became from that time the place of residence of the Order, till their final expulsion in the sixteenth century. Five years after their settlement they sustained a formidable siege from Othman, the Turkish sultan, and, notwithstanding the unprepared state of their fortifications, succeeded in repulsing him, and a few years afterwards his son Orkan. From this period they continued to resist the constantly increasing power of the Turks, for about 200 years, adding to the advantages of a position naturally very strong the most skilfully designed fortifications that could be devised in the fourteenth and fifteenth centuries, and making the numerical superiority of the infidels of little avail, by their better organization in the field, more efficient weapons and armour, and incredible valour. In 1344, in the grand-mastership of Helcon de Villeneuve, they attacked and took Smyrna, which they maintained as an outpost. Three years afterwards they came in contact with a new enemy, the Sultan of Egypt, against whom they defended the king of Armenia. The project of removing the knights to Syria or the Morea having been abandoned at length by Innocent VI., they continued their enterprises against the sultan of Egypt, and making a sudden descent, plundered Alexandria, A.D. 1365, but did not make any permanent conquest in that country. At the close of this century the Order engaged in a league to check the increasing power of Bajazet, and sustained a severe loss at the fatal battle of Nicopolis. In 1401 Tamerlane deprived them of Smyrna. During the grand-mastership of John de Lastic, they carried on a war with the sultan of Egypt, which was terminated by a siege of Rhodes, lasting 40 days, in which the Saracens were repulsed with great slaughter. The Turkish empire having somewhat recovered from the effects of the invasion of Tamerlane, Mahomet II. laid siege to Rhodes in 1480, and, notwithstanding the immense force of artillery employed against it, could not take the place. The last and most memorable siege of Rhodes was June, 1522, by the Turks, conducted by their sultan Solyman II. The princes of Christendom, thinking probably that it was hopeless to attempt the defence of so distant an outpost, abandoned Rhodes to its fate, and its gallant inhabitants held out till they were nearly buried in the ruins of their fortifications. Their grand-master, Villiers de Lisle Adam, entered into a capitulation in December the same year, and evacuated Rhodes on honourable terms. The history of the Order from this time belongs to that of Malta. [MALTA.] The island has ever since remained a province of the Turkish empire.

The greatest length of Rhodes, from north to south, is about twelve leagues, according to Sonnini (*Voyage en Grèce et Turquie*), its breadth six leagues, and its circuit is commonly estimated at forty-four leagues. Strabo makes the circuit 920 stadia. On the western coast is the site of the antient Camirus. On the eastern, at the northern extremity of the island, is the city of Rhodes, to the south of which is Lindus, and a small river, the Camdura, below which is Cape Tranquillo, the southernmost point of the island. The whole of this side of the coast is indented by deep bays formed by projecting headlands, and capable of affording protection for shipping. Towards the centre of the island is the mountain Artemira, the Atabyris of Strabo, which commands a magnificent view of the Archipelago, the woodland scenery of the island forming a rich foreground sloping down to the coast, and the distance being bounded, on the Asiatic side, by the picturesque outline of the Lycian hills.

The air is mild and healthy, and fragrant from the number of orange and citron groves and of aromatic herbs. The statement of Pliny, that scarcely a day in the year passes without sunshine, is confirmed by the present inhabitants. The winds are chiefly north or north-west during almost every month; sometimes they blow with great violence. The soil is fertile, and there are numerous springs. The fig-tree and the vine still flourish, and corn is grown, though only enough for the consumption of the inhabitants. Antiently many articles of commerce were exported, which were in much esteem among the Greeks and Romans. Pliny and other authors mention glue, pitch, honey, and saffron ointment; but Turkish misrule here, as in the rest of the Levant, has counteracted the natural advantages of situation, climate, and products.

The population has been somewhat differently estimated. Savary, whose 'Lettres sur la Grèce' were published in 1788, reckons it at 37,500; in Fuller's 'Turkey,' a later work, it is put down at about 40,000; and in Turner's 'Journal of a Tour in the Levant,' 1820, it is thus stated: —14,000 Greeks, 5000 Turks, and 1000 Jews. There are, according to this last writer, forty-two Greek villages, and the rest are Turkish.

The inhabitants are governed by a bey, who holds his office for life, a circumstance which is favourable to the inhabitants, who are less oppressed than in other Turkish governments, where there is a more frequent change of masters. The bey farms the revenues and pays an annual sum of half a million of piastres every year to the Porte, besides fitting out a frigate every two or three years. Ship-building is the chief employment of the Rhodians.

At Lindo, or Lindus, there are ruins on an eminence near the sea, which Savary supposes to be those of the temple of Athena Lindia, the work, according to Strabo (p. 655, Casaub.), of the Danaides. The harbour is frequented by small craft, and the inhabitants carry on some trade. No remains of Camirus or Ialysus have been discovered.

Of the town of Rhodes there are no remains earlier than the time of the knights, but all their works are interesting specimens of the military architecture of the middle ages. On entering Rhodes from the sea, two harbours, separated by a narrow quay, present themselves; the larger, to the north, is called Mandraici, and the smaller is named the Port; the narrow quay which separates them forms a curve, having on its extremity next the sea a round tower, and farther inland a square one of great strength and crowned with turrets of observation at the four corners. According to Thévénot, this tower was built by the Turks, on the site of the tower of the same name so often mentioned in the sieges of Rhodes in the time of the knights. Attached to it is a curtain, which connects it with the fortification of the town within. From the other side of the smaller port a narrow quay juts out, on which is another round tower. The Turks have suffered the entrance to Mandraici to be so much obstructed as to impede the navigation.

The castle of the Order in the town, containing the cells of the knights in one street, the cathedral, with curiously carved wooden doors, and with the arms of England and France on its walls, was still in a very perfect state when Dr. Clarke visited the island in 1801, and it retained its portcullises and drawbridges.

This traveller speaks of it with great admiration, and Fuller ('Turkey') recognises the same style of architecture as that which he saw in the fortifications of the knights at Malta. There are remains of several other churches in Rhodes. The inhabitants of the higher classes live in the suburbs, which are very extensive and full of beautiful gardens; the Christians live in a quarter by themselves, called Villagio Novo.

For the antient history of this island, the dissertation of Meursius, which contains most of the passages in the classical writers relating to Rhodes, Müller's 'Dorians,' and a dissertation in Latin on the Macedonian period, by Paulsen, printed at Göttingen, may be consulted. For the modern history, see Vertot's 'Chevaliers de St. Jéan,' Coronelli, 'Isola de Roda,' and other authorities which may be found in Meusel's 'Bibliotheca Historica.' A very curious work, by Gulielmus Caoursin, vice-chancellor of the Order, gives a history of its siege in 1480, with wood-cuts of the harbour and operations of the siege, printed at Ulm, by John Reger, 1490.

Other views of Rhodes may be seen in Dapper's 'History of the Archipelago,' translated into French from the Flemish, and in Lebrun's 'Travels.'

RHODEZ, or RODEZ, a city of France, capital of the department of Aveyron, 312 miles in a direct line, almost due south of Paris, or 356 miles by the road through Nevers, Moulins, Clermont, and St. Flour; in 44° 20′ N. lat. and 2° 33′ E. long.

This town is mentioned by Ptolemy under the name of (Σεγόδουνον) Segodunum, as capital of the Ruteni (Ῥουτανοί) a Celtic people, included in the enlarged province of Aquitania by Augustus. It subsequently took the name of Ruteni, from which have been derived both the modern name of the town, Rhodez, and that of the county of Rouergue, of which, in the middle ages, it was the capital. [ROUERGUE.] Rhodez had also counts of its own, whose dominions came into the hands of the counts of Armagnac, and were not finally united to the crown until the accession of Henri IV., who had inherited them.

The town stands on a considerable eminence on the northern bank of the Aveyron, 2173 feet above the level of the sea, and nearly 500 feet above the bed of the river. It is surrounded by antient walls, now converted into a terraced walk or garden. The streets, from the rapid slope of the hill on which the town is built, are steep; they are also narrow, crooked, dark, and dirty, lined with ill-built wooden houses with projecting upper stories, which are however being gradually displaced by others of better architecture. There are four 'places' or squares, two of them of tolerably regular form. The cathedral is for the most part Gothic, of the earlier part of the fifteenth century, but with some incongruous additions. The size of the nave, the boldness of the vaulted roof, the beauty of the stained-glass windows, and the height of the bell-tower (to which some writers assign an elevation of above 265 English feet) render it a striking edifice. The office of the prefect is a modern building; the other chief public buildings are, the college, built by the Jesuits, and the seminary for the priesthood.

The population of the commune of Rhodez, in 1826, was 7747; in 1831, 8249 (of whom 7879 were in the town); and in 1836, 9685. The inhabitants manufacture woollen yarn, coarse woollen cloths, serges and other woollen stuffs, hats, wax and other candles, and playing-cards. There are tan-yards and dye-houses. The trade of the place is in the manufactured articles, in the wool grown in the neighbourhood and the grey cloth made from it, and in cheese. There are four yearly fairs. Silk-worms are reared, and mules for the Spanish market bred round the town.

Rhodez is the seat of a bishopric, the diocese of which comprehends the department, and the bishop of which is a suffragan of the archbishop of Alby: it has several judicial and fiscal government offices, an exchange, a chamber of manufactures, an agricultural society, a departmental nursery-ground, and a public stud, an hospital, cabinets of natural history and of natural philosophy, a public library of 15,000 volumes, a deaf and dumb school, a school for outline drawing, a theatre, and public baths.

The arrondissement of Rhodez contains 183 communes: it is divided into eleven cantons or districts, each under a justice of the peace. The population, in 1831, was 94,568.

RHO'DIUM, a metal discovered by the late Dr. Wollaston, and named from *rhodon* (ῥόδον, a rose), on account of the colour of one of its solutions. This metal exists in combination with platinum. According to the analysis of Berzelius, the ore of Colombia contains nearly three and a half per cent., and that of Siberia only 1·15 per cent. of rhodium. When the greater part of the platinum and palladium have been separated from the solution of the native grains, a plate of iron is to be immersed in the residual solution, and by this the rhodium, with small quantities of platinum, copper, and lead, is thrown down in the metallic state. In order to render the rhodium pure, it is first digested in dilute nitric acid, which dissolves the copper and lead, and the rhodium and platinum are then to be dissolved in nascent chlorine (aqua regia) mixed with some common salt, and the solution is to be evaporated to dryness. By this operation there are obtained the double chloride of platinum and sodium, and rhodium and sodium. The former is to be dissolved in alcohol, and the latter afterwards in water, and a plate of zinc immersed in the solution precipitates the rhodium in the metallic state. The metal thus procured is in the state of a black powder, and requires the strongest heat of a wind-furnace for fusion.

The properties of rhodium are, that it is white, has a metallic lustre, is brittle, extremely hard, and its specific gravity is about 11. It is not dissolved by any acid or by nascent chlorine (aqua regia), except when it is alloyed by other metals; and this circumstance accounts for its being dissolved, when alloyed with platinum, in the native grains of this metal. It suffers no change by exposure to air, either dry or moist.

Oxygen and Rhodium.—These cannot be made to combine by direct action, and it is probable that the protoxide has not been insulated. When finely-divided rhodium, mixed with potash and a little nitre, is heated to redness in a silver crucible, the metal is oxidized, and becomes of a brown colour, and is mixed with potash; the mass is to be washed with water, and then treated with hydrochloric acid, by which hydrated peroxide of rhodium is left, of a greenish grey colour. It consists of about—

One and a half equivalent of oxygen .	12
One equivalent of rhodium . . .	52
Equivalent . .	64

When this peroxide is heated, it becomes black, and is then probably converted into protoxide, composed of—

One equivalent of oxygen . . .	8
One equivalent of rhodium . .	52
Equivalent . .	60

Chlorine and Rhodium probably unite in two proportions, but the perchloride only has been hitherto obtained in a separate state. It was procured by Berzelius by adding silico-hydrofluoric acid to a solution of the chloride of potassium and rhodium, as long as the double fluoride of potassium and silicium was generated, after which the filtered liquor was evaporated to dryness, and the residue redissolved in water. The remaining perchloride thus obtained has a dark brown colour, and when heated to redness, chlorine is evolved and metallic rhodium obtained. The aqueous solution of this salt is a fine rose-red colour, whence the name of the metal which it contains.

It is a sesquichloride, composed of—

One and a half equivalent of chlorine .	54
One equivalent of rhodium . .	52
Equivalent . .	106

This salt forms double compounds, called rhodio-chlorides, with the chloride of potassium and of sodium; they consist of one equivalent of each.

Sulphur and Rhodium may be made to combine by heating them together, the metal being in a state of minute division; it fuses at a white heat without decomposition, has a bluish-grey colour, a metallic lustre, and by the action of nitric acid is converted into sulphate of rhodium. Sulphuret of rhodium may also be formed by heating the amonio-chloride of the metal with sulphur, or by heating its solution with sulphuret of potassium.

Alloys of Rhodium.—When combined with steel to the amount of only two per cent., it gives the steel great hardness without occasioning it to crack under the hammer. Dr. Wollaston has examined several of its alloys, and, on account of its hardness, he suggested its employment for the nibs of metallic pens; to which purpose it has been applied successfully. It has not been combined with mercury.

Salts of Rhodium.—The salts of the peroxide only have been formed. Their general properties are but little known.

Nitrate of Rhodium is obtained by dissolving the peroxide in the acid: it is of a deep red colour, and uncrystallizable.

Sulphate of Rhodium is procured, as already mentioned, by acting upon the sulphuret with nitric acid. The solution is of a deep red colour, and does not yield crystals. When the caustic alkalis are added to the solution of this salt, a precipitate of the hydrated sesqui-oxide of a greenish-yellow colour is obtained after some time; the alkaline carbonates produce no effect, nor does sulphurous acid, nor the ferrocyanide of potassium. Hydrosulphuric acid throws down sulphuret of rhodium; but the hydrosulphates of ammonia and potash produce no immediate precipitate.

RHODOCRINI'TES. [ENCRINITES, vol. ix., p. 393.]

RHODODENDRON, a genus of evergreen shrubs, very common in gardens, is one which differs from Azalea [AZALEA] principally in the stamens being 10 instead of 5, in the corolla being campanulate, not tubular, and in the foliage being hard and evergreen. The species are nearly related to each other, and occur both in the new and old worlds. Of the numerous varieties to be seen everywhere in flower in this country, in the months of May and June, the greater part belong to R. ponticum, a species found wild on the coasts of the Black Sea from the range of Caucasus through Armenia and Georgia to the western frontier of Persia, or to R. catawbiense, an American species, or to hybrids between these. R. ponticum was at one time supposed to be the plant which rendered the honey of Asia Minor poisonous; but it has been ascertained that the effect is really produced by Azalea pontica. In the warmer parts of India there occurs the tree Rhododendron, with crimson or white or pink flowers, one of the most beautiful of all trees, too tender to bear the open air in England, but a noble object in a conservatory; there are also some mountain species on the Himalayas, one of which, R. campanulatum, is strikingly handsome, and quite hardy. By means of crossing the crimson tree Rhododendron with some of the hardy species, a race of hybrids has arisen, which are much cultivated as hardy greenhouse plants, and in Ireland and some of the milder parts of England they will endure the open air without protection. They are perhaps more beautiful than any of their parents. The most curious of these hybrids is a yellow one recently obtained by Mr. Smith, a nurseryman near London, by crossing a Rhododendron with the yellow Chinese Azalea; this is perhaps one of the finest artificial productions yet obtained by florists. The Alpine Rhododendrons, hirsutum and ferrugineum, with small campanulate crimson flowers, are handsome dwarf shrubs in elevated situations, but they dislike the low grounds near London. The leaves of *R.* chrysanthum, a species with yellow flowers from Siberia, have a great reputation as a remedy for chronic rheumatism; its effects are those of a powerful narcotic.

RHODOMANNUS, LAURENTIUS, was born in 1546, at Sassawerft, on the estates of the counts of Stolberg. His parents were poor, and as the boy early displayed great talents, count Stolberg sent him at his own expense to the gymnasium at Ilfeld. Greek literature, which was then reviving in Germany, had most attractions for him, and he made it his principal study at the university of Rostock. After the completion of his studies, he held several offices as teacher, but was afterwards invited to the professorship of Greek literature in the university of Jena, and subsequently to that of history at Wittemberg, where he died on the 8th of January, 1606.

Rhodomannus is said to have been extremely ugly, but his learning and amiable qualities soon effaced the unfavourable impression created by his appearance. His greatest merits consist in his efforts to diffuse a taste for Greek poetry, and he endeavoured to attain this object by making Greek verses himself, in which he is said to have been very successful. We still possess a number of works by Rhodomannus, in Greek verse with Latin translations, viz.: 'Vita Lutheri, Græco carmine descripta et Latine reddita,' Ursel, 1579; 'Descriptio historiæ ecclesiæ, &c., Græco carmine cum versione Latina, e regione textus Græci,' Frankfurt, 1581; 'Poesis Christiana, id est, Palæstina, seu Historiæ Sacræ, Græco-Latinæ, libri ix.,' Marpurg, 1589; 'Theologiæ Christianæ Tyrocinia, carmine heroico Græco-Latino, libri v.,' Lipsiæ, 1597, &c. Rhodomannus also made some Latin translations of Greek authors, as of Diodorus Siculus, which is printed in the edition of H. Stephens (1604); of the 'Posthomerica' of Quintus Calaber; he also made a translation of extracts from 'Photii Bibliotheca' and Diodorus Siculus, under the title of 'Memnonis Historia de Republica Heracleensium et Rebus Ponticis Eclogæ,' Helmstadii, 1591, and reprinted at Geneva in 1593. Rhodomannus edited the following collection of Greek poems:—'Anonymi Poetæ Græci: Argonautica, Thebaica, Troica, Ilias parva, Arion, Narratio de Bello Trojano e Constantini Manassis Annal.,' &c., Lips., 1588. His Life has been written in Latin, by Ch. H. Lang, Lübeck, 1741.

RHODOPHY'SA. [PHYSOGRADA, vol. xviii., p. 138.]

RHOEMETALCES. [THRACE.]

RHOMB, RHOMBUS, RHOMBOID. These terms have been used in various significations by different writers, and the second and third have been sometimes distinguished from each other in meaning. It is not worth while to do more than state, that when either of them is now used, it signifies an equilateral oblique parallelogram. The Latin dictionaries define rhomboides to be a parallelogram, and rhombus an equilateral parallelogram.

RHOMBOI'DES (Conchology), De Blainville's name for a genus described as bearing a resemblance to *Byssomya* in its shell, but as differing in the soft parts. *Mytilus rugosus*, Gmel.; *Hypogæa barbata*, Poli.

RHOMBUS (Conchology), De Montfort's name for a genus of *Cones*, of which *Conus nocturnus* may be regarded as the type. [CONUS, vol. vii., p. 485.]

RHOMBUS MA'XIMUS. [PLEURONECTIDÆ.]

RHÔNE, River. [FRANCE.]

RHÔNE, a department of France, the smallest except the metropolitan department of Seine, bounded on the north by the department of Saône et Loire, on the east by that of Ain, on the south-east by that of Isère, and on the south and west by that of Loire. Its form approximates to an oval, having its greatest length from north to south, from the neighbourhood of Aigue Perse in the Charolais mountains to Condrieu on the Rhône, 60 miles; and its greatest breadth at right angles to the length, from the neighbourhood of Lyon to near Panissière in the department of Loire, 28 miles. Its area is only 1080 square miles, being less than half the average area of the French departments, and about equal to the area of the English county of Durham. The population, in 1826, was 416,575; in 1831, it was 434,429; and in 1836, 482,024, showing an increase in the last five years of 47,595, or nearly 11 per cent., and giving more than 446 inhabitants to a square mile. In amount of population it exceeds the average of the departments in the proportion of nearly 4 to 3; and in density of population, in the proportion of nearly 3 to 1; in amount of population it exceeds every English county except Yorkshire, Middlesex, Lancashire, Devonshire, and Surrey; and in density of population, every one except Middlesex, Lancashire, and Surrey. Lyon is the chief town. [LYON.]

The western side of the department is mountainous; the Lyonais, Beaujolais, and Charolais heights, which form the prolongation northward of the Cévennes, extend through it on this side from south to north. From a point in the north of the department near the town of Beaujeu, these heights send off two offsets, one (the Mâconnais heights) to the north-north-east, which are separated from the principal range by the valley of the Grône, a feeder of the Saône, and another to the south-south-east, which are separated from the principal range by the valley of the Azergue, another feeder of the Saône. In the south of the department another offset branches off from the main range, from which it is separated by the valley of the Brevanne, and extends north-east to the banks of the Saône, north of Lyon; its extremity is known as Mont d'Or, a name which is sometimes given to the whole branch. The extremity of another branch running to the north-east and separated from the main range by the valley of the Gier, just extends into the southern part of the department. Some of the peaks are of considerable height; the mountain of Tarare is on the north side about 2600 feet, in the centre nearly 3000 feet, and on the south nearly 4500 feet. The Mâconnais heights have in some places an elevation of above 3000 feet. The principal pass over these mountains is that of Tarare, where the road from Paris by Moulins to Lyon crosses the range. Southward of this are the passes through which run the roads from Lyon to Feurs and to St. Etienne; northward of it the only pass in the department is that through which runs the road from Beaujeu to Charlieu. The road from Lyon along the western bank of the Rhône runs in several places through a narrow pass between the lower yet rapid slopes of the mountains and the river.

The principal mass of the mountains is composed of granitic or other primary rocks. In the valley of the Gier are found the lower secondary formations; while the valley of the Rhône is occupied, in the north, by the secondary formations, and in the south by the super-cretaceous or tertiary formations.

The mineral wealth of the department, though of various kinds, is not of any great value. There was only one coal-mine worked in 1834 (one had been given up); it produced 7577 tons of coal, valued at 3881*l.*: the quantity of coal produced in the department in 1835 was 7463 tons. Three mines produced lead in 1836, but the quantity was only ... tons, valued at 98*l.*: two produced a small quantity of copper. The copper-mines are at St. Bel near Arbresle on the Brevanne, and at Chessy on the Azergue: they were worked by the Romans. Rock crystal, porphyry, granite, fine marble of various colours, sandstone, gypsum, potters' and fullers' earth, manganese, and excellent freestone are found. Some particles of gold are brought down by the Rhône. There are some chalybeate waters at Charbonnières near Lyon, but not of much importance.

The principal range of the mountains which we have described separates the basin of the Rhône from that of the Loire; the eastern slope being in the former, the western in the latter. As the ridge is not far within the western boundary, almost all the department is included in the basin of the Rhône, only a small part of the western side being in that of the Loire. The Saône touches the eastern boundary of the department, about 10 miles below Mâcon: this river or the Rhône forms the eastern boundary to Condrieu adjacent to the southern extremity of the department, except just in the neighbourhood of Lyon, where the department extends across so as to comprehend a portion of the eastern bank of both rivers. The affluents of the Saône are, the Grône, of which only the source and just the upper part of the course are in this department, the Ardière, and the Azergue. The Azergue receives the united streams of the Brevenne or Brevanne and its feeder the Tardine. The feeders of the Rhône are the Izeron, the Garon, and the Gier, of which last only the lower part belongs to the department. Of the feeders of the Loire, the Sornin, the Trambouze, the Loise, and the Coize have their sources in this department. None of these rivers are navigable except the Saône and the Rhône.

The only canal is that of Givors, which extends along the valley of the Gier from Rive de Gier to Givors. The length of water communication is given in the official statements as follows:—

Saône	. . .	38 miles.
Rhône	. . .	32 „
		—
Rivers	. . .	70 miles.
Canal of Givors	. .	6 „
		—
	Total .	76 miles.

There are six government roads, having an aggregate length (1 January, 1837) of 146 miles, viz. 111 miles in repair, 12 miles out of repair, and 23 unfinished. The principal roads are those from Paris to Lyon. The road by Auxerre and Châlons (with which the road by Dijon unites) enters the department on the north side, and follows the valley of the Saône through Villefranche and Anse. The road by Moulins enters the department on the west side, and runs by Tarare and Arbresle. From Lyon two roads run, one across the Alps to Chamberi and Turin; the other along the valley of the Rhône (by the east or left bank) to Avignon, and thence to Aix, Marseille, Toulon, and Genoa; but only a very small portion of these two roads is in the department. Roads also lead from Lyon by Grezieux, Izeron, and Rivoire to Feurs in the department of Loire, and thence to Clermont-Ferrand; by St. Genis-Laval and Brignais to Rive de Gier and St. Etienne, in the department of Loire; and along the valley of the Rhône, branching off from the St. Etienne road at Brignais, and passing through Millery, Givors, and Condrieu to Le Pont St. Esprit, Nîmes, and Montpellier. The departmental roads had an aggregate length of 169 miles, viz. 105 in repair, 18 out of repair, and 46 unfinished. The bye roads and paths had an aggregate length of above 1500 miles. There is a railroad from Lyon to St. Etienne, and one from St. Etienne to the Rhône at Givors, a branch (we presume) of the other.

The climate is healthy, but the temperature is various, owing to the varying elevation of the surface. This inequality is unfavourable to cultivation upon a large scale. The surface may be estimated in round numbers at 700,000 acres; of which about 360,000 acres, or more than half, are under the plough. The banks of the Saône are remarkably fertile, and much wheat is grown there. The grain harvest is abundant, but, from the density of the population, altogether insufficient to supply the wants of the inhabitants. Pulse, colza, madder, millet, saffron, flax, and hemp are also cultivated. The meadows comprehend 90,000 acres; the heaths and open pastures, about 30,000. Neither horses nor oxen are numerous, or of a good breed; the number of cows is very great, approaching 50,000. Sheep are numerous. Asses are both numerous and good; and on Mont d'Or a number of goats are fed, from whose milk good cheese is made. The vineyards occupy above 75,000 acres; some of the finest wines in France are produced here, especially the Côte Rôtie, Romanêche, Ste. Foy, and Condrieux. The fruits both of northern and southern France are grown, except the orange and the olive; and the chesnuts are sent to Paris and sold under the name of Lyon chesnuts. The mountains are for the most part covered with wood: Mont Pilat in particular is covered with fine firs: the woodlands occupy about 85,000 acres.

The waters furnish a good supply of fish. The pike, the eel (some of great size), the barbel, excellent trout and perch, and other fish, are taken in the streams; and the shad, the lamprey, and the sturgeon ascend the Rhône. The eel-pouts of the Saône are excellent.

The department is divided into two arrondissements, as follows.—

Name.	Situation.	Area in sq. m.	Cantons.	Communes.	Population. 1831.	Population. 1836.
Lyon .	S.	500	16	126	292,370	330,044
Villefranche	N.	580	9	127	142,059	151,980
		1080	25	253	434,429	482,024

In the arrondissement of Lyon are—LYON; St. Genis-Laval; Millery, population 1500 for the town, 1525 for the whole commune; Givors, population 4385 for the town, or 4884 for the whole commune; Ste. Colombe; and Condrieu, or Condrieux, population 3090 for the town, 3864 for the whole commune, are all on or near the Rhône. St. Andéol is near the Gier, Riverie and Mornant between the Gier and the Garon, Brignais on the Garon, Izeron on the Izeron, Grezieux on the road from Lyon to Clermont, Arbresle near the junction of the Tardine and the Brevenne, St. Laurent and St. Bel near the Brevenne, Montrotier near a feeder of the Brevenne, and Chesseay or Chasselan and Neuville on the Saône; all these are in the basin of the Rhône, east of the Lyonais mountains. On the west side of the ridge, in the basin of the Loire, are St. Symphorian and Rivoire. St. Genis-Laval is a handsome little town, with a 'place,' or square, planted with trees. The townsmen manufacture paper-hangings, paper-stainers' colours, printers' ink, writing ink, buttons, carpets, banners, and paintings for churches. Considerable trade is carried on in wine, of which some very good is grown in the neighbourhood. There are five cattle-fairs in the year. Considerable trade in wine is also carried on at Millery. Givors, standing at the junction of the canal of Givors with the Rhône, and at the terminus of the railroad from St. Etienne, is a busy town, in a fertile and pleasant district. The townsmen manufacture window-glass, glass bottles, and drinking-glasses, and dye silk. There are three yearly fairs for nails, glass, and cattle. At Condrieu, or Condrieux, the townsmen carry on manufactures of silk and leather, dye silk, and refine salt: they carry on trade in corn, and in the much esteemed white wines of the neighbourhood. There is a good weekly cattle-market, and there are six yearly fairs. A considerable number of the inhabitants are boatmen on the Rhône, and many boats are built here. At Mornant coarse woollen cloth and hats are manufactured; there are four yearly fairs. Brignais has the ruins of an aqueduct, supposed to be of Roman construction, and several handsome country-houses belonging to the inhabitants of Lyon. Some trade in cattle is carried on, and a good deal of wine is grown round the town. Near Izeron, sometimes written Yzeron, fine granite is found. An antient Gothic castle of picturesque and imposing appearance distinguishes Arbresle. The town itself is modern, having been rebuilt after a destructive inundation in 1715. Some cottons are manufactured at St. Laurent, and there are copper-mines at St. Bel, but so unprofitable that it has been proposed to give up working them. At Neuville, distinguished as Neuville l'Archevêque, cotton-yarn is spun, silk thrown, linen bleached, and paper and sheet-lead made. There are seven yearly fairs.

In the arrondissement of Villefranche are—Villefranche, population in 1831, 6460; in 1836, 7553; Belleville; and Anse; all near the Saône; Chamelet, Yoingt, Bois d'Yoingt, Chessy, Châtillon, and Chazay, on or near the Azergue; Tarare, population 5990 for the town, 6833 for the whole commune; Beaujeau, population 1520 for the town, or 1596 for the commune, on the Ardière; and Jullie, near the northern boundary of the department: all these are in the basin of the Rhône. West of the Lyonais and Beaujolais mountains, in the basin of the Loire are the towns of Amplepius, population 4873, and Thizy, on feeders of the Trambouze; and Aigueperse near the northern frontier. Villefranche was founded, near the end of the eleventh century, by Humbert, Sire de Beaujeu. The town consists of one very wide and handsome street, extending for above a mile along the road from Paris to Lyon, and of some smaller streets branching from it. The houses are well-built. The inhabitants manufacture cotton yarn, cotton goods, and leather. There are three yearly fairs, and a considerable weekly market for cattle, chiefly for the supply of Lyon, hemp, flax, cotton yarn, and cotton and hempen cloth. Considerable trade is carried on in hides and wine. There are some subordinate government offices, judicial and fiscal; a high school, and hospitals. There were formerly lead-mines near the town, which were worked by the Romans. Belleville, distinguished as Belleville sur Saône, has a manufacture of muslins and other cottons, also of linens: trade is carried on in wine. The town lies just out of the road from Paris by Mâcon to Lyon. Anse is agreeably situated in one of the richest plains in France, at the foot of a hill covered with vineyards. Linen-bleaching is carried on at Chamelet. Yoingt has the ruins of an antient castle, the chapel of which now serves as a parish church. Chessay has important copper-mines, and works for smelting and rolling the copper. Tarare, in a narrow valley at the foot of Mount Tarare, over which the road from Paris by Moulins to Lyon has been carried with great labour, is a tolerably well-built and very busy town. It is the centre of a manufacture of muslin and embroidery, which employs 50,000 workmen scattered over the neighbouring country: it has print-works, bleach-grounds, tan-yards, and potteries: there are two yearly fairs. The neighbouring mountain contains lead-ore, but the mines have been given up marble is quarried. The town has at times suffered considerably from the swelling of the little river Tardine, on which it stands. Beaujeu, the antient capital of Beaujolais, is a neat town, at the foot of a mountain crowned with the ruins of the old castle of the Sires de Beaujeu. There are cooperages, paper-mills, and tan-yards. A considerable trade is carried on in grain, wines, and iron, and in the cottons and linens manufactured in the district round. It has six yearly fairs. At Amplepius and Thizy linens and cottons are manufactured; and at Cours, a large village near Thizy, a mixed fabric of cotton and flax is woven. There are twelve fairs at Thizy, which is the mart for the surrounding country.

The department constitutes, with the adjacent department of Loire, the archiepiscopal diocese of Lyon and Vienne: it is in the jurisdiction of the Cour Royale of Lyon, and the authority of the Académie Universitaire of that city. It is in the nineteenth military division, the head-quarters of which are at Lyon. It sends five members to the Chamber of Deputies. In respect of education it is above the average of France; of the young men enrolled in the military census of 1828-29, 45 in every 100 could read and write; the average of the departments being under 40.

The district now included in the department was antiently part of the territory of the Segusiani (Σαιγοσιανοί and Σεγοσιανοί, Strabo), a people dependent on the Aedui, and perhaps of the Insubres (Ἰνσουβροι, Strab.), who appear to have been either dependents of the Aedui or a part of their nation. It is probable that the bank of the Saône above Anse belonged to the Ambarri, also dependents of the Aedui; the neighbourhood of Beaujeu appears to have been comprehended in the territory of the Aedui (Αἰδουοί and Ἐδοῦοι, Strabo; Αἰδουοι, Ptol.) themselves; and the bank of the Rhône south of Givors belonged to the Allobroges (Ἀλλόβρογες, Strabo; Ἀλλόβρυγες, Ptol.). These nations all belonged to the great Celtic stock. This part of Gaul was the seat of contest in Cæsar's war with the Helvetii, in the first year of his command in Gaul. The Rhône and the Saône were known to the antients by the names of Rhodanus (Ῥοδανὸς, Strabo) and Arar (Ἄραρ, Strabo).

In the Roman division of Gaul, this territory was included in the province of Lugdunensis, afterwards of Lugdunensis Prima; except the portion which belonged to the Allobroges, which was included in Narbonensis, the 'provincia nostra' of Cæsar, and upon the subdivision of that province, in Viennensis. A few towns, Roman or Celtic, were included in its limits. Lugdunum (Λούγδουνον, Strabo and Ptolemy), now Lyon, the most important, is noticed elsewhere. [LYON] The Mediolanum of the Peutinger or Theodosian Table is fixed by D'Anville at Meys, a village near the western boundary of the department, between Lyon and Feurs; the Assa or Asa Paulini of the Antonine Itinerary may be fixed at Anse; and the Lunna of the same authority was somewhere upon or near the northern boundary of the department, between Lyon and Mâcon.

On the overthrow of the Roman empire it passed into the hands of the Burgundians and Franks. In the middle ages it constituted part of the counties or provinces of Lyonais in the south, and Beaujolais in the north, so called from their chief towns Lyon and Beaujeu; and both subdivisions of the province, to which, in a more extended sense, the name of Lyonais was given. [BEAUJOLAIS; LYONAIS.] When France was first divided into departments by the National Assembly, A.D. 1790, this department, with the adjacent one of Loire, formed one department under the name of Rhône et Loire. The separation was afterwards made by the National Convention.

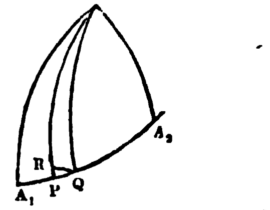
RHUBARB. [RHEUM.]

RHUMB or RUMB. Vitalis (*Lex. Math.*) calls this a Portuguese word, and no doubt it might have been introduced into navigation by the Portuguese, but we suspect it to be the Latin 'rhombus': he says it signified originally the meridian, or the principal meridian of a map; perhaps it came to signify this from such meridian being usually ornamented by a distinctive rhombus, such as is added to the north direction on a compass-card. However this may be, a rumb certainly came to mean any vertical circle, meridian or not, and hence any point of the compass; so that, in modern phraseology, a rumb is one of the thirty-two principal compass directions, and to sail on any rumb is to sail continually on one course. Hence a rumb-line is a line drawn in the sphere, such as would be described by a moving point which always keeps one course; it is therefore the spiral described in MERCATOR'S PROJECTION, and is that which is also called the loxodromic spiral.

The mathematical properties of the rumb-line may be easily deduced. Let r be the radius of the earth, λ_1 and l_1 the longitude and latitude of A_1, and λ_2 and l_2 those of A_2, λ and l being those of any intermediate point P: and let s be the length of A_1P. If then we increase s by the infinitely small arc ds, increasing λ and l at the same time by $d\lambda$ and dl, we have the differential triangle PQR, in which $PQ=ds$, $PR=rd\lambda$, $RQ=rdl.\cos\lambda$, while the angle RPQ, which is the same throughout the curve, may be called ρ. We have then $ds.\cos\rho=rd\lambda$, or $s.\cos\rho=r(\lambda-\lambda_1)$ integrating from A_1 to P. Again, $ds.\sin\rho=rdl$ $\cos\lambda$, so that the two equations give

$$\frac{d\lambda}{\cos\lambda}=dl\cot\rho,\quad\text{or}\ \log\cot\left(\frac{\pi}{4}-\frac{\lambda}{2}\right)=l\cot\rho+C;$$

the logarithm being Naperian, and the angles being measured as in ANGLE, vol. ii., p. 23. If L be the length of the



arc of a degree of longitude at the equator, and if we now use degrees, and extend the preceding integration from A^1 to A_2, we have—

$$r\log\frac{\cot(45^\circ-\frac{1}{2}\lambda_2)}{\cot(45^\circ-\frac{1}{2}\lambda_1)}=(l_2-l_1)\,L\cot\rho;$$

an equation from which ρ can be found for any two places, that is, the angle which the course in sailing from one place to the other makes with the meridian. And instead of $r:L$ may be put its value 57·29578. The distance from one place to the other on the rumb-line sailed over may be found from $s\cos\rho=r(\lambda_2-\lambda_1)$, which, when λ_2 and λ_1 are measured in degrees, becomes $s\cos\rho=(\lambda_2-\lambda_1)L$, neglecting the small correction for the earth's excentricity.

The first of these processes can be done by Mercator's chart, the principle of which, mathematically described (with which the popular description given in MERCATOR'S PROJECTION agrees), is as follows:—Let equal arcs of longitude remain equal throughout the map, but as increments of latitude are to their corresponding increments of longitude as 1 to the cosines of the latitudes, let the differential triangle PQR be similar in the chart to that on the sphere which gives $ad\lambda:\cos\lambda$, for the representation of $d\lambda$ on the chart, provided a represent the length of the degree of longitude on the chart. Hence $a\cot(45^\circ-\frac{1}{2}\lambda)$ is the length of λ degrees of latitude measured from the equator; and a table of values of $\cot(45^\circ-\frac{1}{2}\lambda)$ is called a table of *meridional parts.*

In such a chart all rumb-lines are projected into straight lines; but equal parts on any such straight line do not represent equal distances on the earth: and the distance sailed must be found by the formula in terms of the extreme latitudes and the angle of the course.

RHUS (Sumach, in Greek ῥοῦς), the name of a genus of plants. One of the species, *R. cotinus*, appears to have been known to Pliny, who refers to its dyeing properties, and its place of growth, the Apennines, under the name of Cotinus. (Plin., *Hist. Nat.*, xvi. 18.) This genus has an extensive geographical range, from the south of Europe to the Cape of Good Hope. It is also found in Asia and North and South America. It belongs to the natural order Anacardiaceæ, and to the tribe Sumachineæ. Most of the species are poisonous, but they are much cultivated as ornamental shrubs, especially on account of the beautiful red colour of their leaves in autumn. Many of them are used also for the purposes of dyeing and tanning; as an astringent principle, to which is frequently added an acid, is common to the whole genus.

The genus *Rhus* has the following characters:—Flowers bisexual, or polygamous; calyx small, persistent, five-partite; petals five, inserted under the margin of the disk, imbricate in æstivation; stamens five, hypogynous; ovary one-celled, sessile; fruit, a dry drupe; seeds solitary, exalbuminous; radicle opposite the hilum, and bent downwards along the edge of the cotyledons. Leaves alternate, simple, or compound; panicles axillary or terminal.

De Candolle enumerates about ninety species, to which other writers have made additions, but there is reason to believe that many of the new species are merely varieties. We shall here enumerate only a few of those which have interest on account of being cultivated, or their uses in medicine and the arts.

Rhus cotinus, Venus Sumach, or Wild Olive. Flowers hermaphrodite, arranged in loose panicles of a greenish yellow colour; leaves simple, entire. This is a very ornamental shrub, and is one of the European species, growing wild in various districts of the south of Europe. It is made use of, like many other of the species, for tanning, in Italy, and is called *Scotino*. The wood is used by the modern Greeks for dyeing wool, which is said to be of a beautiful rich yellow. It is frequently cultivated on account of its beauty. It requires a dry loam, and is best propagated by pegging down the branches flat to the ground and strewing earth over them, by which means the young shoots, when they grow up, may be removed in the following autumn.

Rhus typhina, Fever Rhus, or Stag's-Horn Sumach. Leaves with eight to ten pair of leaflets and an odd one, lanceolate, acuminate, serrated, pilose beneath. There are two forms of this plant: the one, *arborescens*, in the form of a tree, from ten to twenty-five feet in height; the other, *frutescens*, shrubby, and only from two to ten feet high. The young shoots are covered with down, which, with their somewhat crooked and stunted branches, give them the appearance of young stags' horns; hence their name. The flowers are in dense spikes, at the ends of the branches, the pistilliferous ones developing themselves into woolly drupes, which are very conspicuous when ripe. It is found in every part of North America, and its dark red leaves add much to the beauties of an American autumn. The fruit of this plant is exceedingly sour, and on this account it is frequently called *vinegar plant*, and is even used in some parts as a substitute for vinegar.

Rhus glabra (Smooth-leaved Sumach).—Leaf like the last, but broader and glabrous. Branches also glabrous. Fruit red, covered with silky hairs. Three forms of it are distinguished by De Candolle: *hermaphrodita*, with hermaphrodite greenish flowers; *dioica*, with diœcious green flowers; and *coccinea*, with diœcious red flowers. This last form is the *Rhus elegans* of the nurseries and gardens. This species, as well as another named *R. viridifolia*, is considered by some botanists as only a variety of *R. typhina*. Like the last, this species is abundant in North America, overrunning sometimes a whole district, and forming a troublesome weed. Its fruit is very sour, but may be eaten with impunity. Bees are very fond of the blossoms.

Rhus vernicifera (Varnish-bearing Sumach, or Japan Varnish-tree).—Leaf with 5-6 pairs of leaflets, all ovate, long, acuminate, entire, glabrous above, velvety beneath. It is a native of Japan and Nepaul. Its leaves are very large and beautiful, rendering it one of the handsomest of shrubs. According to Thunberg, this is the plant which yields the celebrated Japan varnish. The varnish is obtained from those branches of the plant which are about two or three years old, by cutting into them, when it oozes out. It is at first white, and of the consistence of cream, but it gets black in colour and much thicker after a little exposure. It is exceedingly transparent, and when used a dark surface of finely powdered charcoal or other substance is placed underneath it. It is very hard, cracking and flying like glass. The Japanese use this varnish very extensively, applying it to their door-posts, windows, household furniture, and in fact to everything made of wood.

Rhus venenata (Poison Sumach, or Swamp Sumach). Leaf 6-7 pair of leaflets, almost glabrous, entire, lanceolate-acuminate, reticulated beneath. Fruit white. It is a native of North America from Canada to Carolina, and also in swampy districts in Japan. This plant is exceedingly poisonous, so virulent that it is said to affect some persons by merely smelling it. A touch will sometimes produce violent inflammation. It is a beautiful shrub, and well worthy of cultivation, but great care should be taken to prevent its being carelessly handled.

Rhus coriaria (Hide or Elm-leaved Sumach). Leaf 5-7 pairs of villous leaflets, elliptical, bluntly and coarsely toothed, petioles naked. Flowers in large loose panicles of a whitish-green. Drupes villous. This plant is a native of the south of Europe. It is extensively used for the purpose of tanning, and it is said that all the leather made in Turkey is tanned with the bark of this species of Rhus. The fruit is acid and astringent, and the seeds are often used as tonics for exciting the appetite.

Rhus copallina (Gum-Copal or Mastich-leaved Rhus).—Leaf glabrous above, slightly pilose beneatn, 5-7 pairs of leaflets and an odd one, lanceolate and entire. Petiole winged and jointed. Root creeping. Flowers yellowish-green, diœcious. It is a native of North America from New Jersey to Carolina. It attains a height of four or five feet. The leaves of this or a similar plant are stated (Don, *Gard. Dict.*) to be used for smoking instead of tobacco by the Indians of the Mississippi and Missouri. It is supposed to yield the gum-copal of commerce, from which copal-varnish is made.

Rhus radicans (Rooting Poison-Oak, or Sumach).—Leaf one pair of leaflets and an odd one, odd one petiolated, glabrous, entire. A native of America from Canada to Georgia. Its climbing habit, combined with the beautiful red colour of the leaf during the decline of the year, renders it one of the most picturesque of American plants. It frequently abounds in the forests, where it may be seen covering the tops of the highest trees. It climbs up walls and rocks, and runs upon the ground with equal facility, thus covering everything withing the reach of its stems. De Candolle distinguishes three varieties: *vulgaris*, with a stem climbing by means of roots; *volubilis*, climbing without roots; and *microcarpa*, with fruit much smaller than the other two. Like the following species, it emits a juice which indelibly stains linen. It is equally poisonous with *R. venenata*. A detailed account of the effects of the poison of the genus Rhus may be seen in Professor Kalm's 'Travels in North America.'

Rhus toxicodendron (Common Poison-Tree, or Poison-Oak).—Leaf of one pair of leaflets and an odd one, with a petiole, inciso-angulate, pubescent. Flowers greenish. It is found in woods, fields, and fences, in common with the last-named species, in North America, where they are both known by the same name. Many botanists consider the two only varieties of the same plant. This species is the type of the genus Toxicodendron of Tournefort. It was introduced into England in 1640, and first grown in the bishop of London's garden at Fulham. This species is that which is most frequently used in medicine.

The less common species of this genus cultivated in Britain are *R. pumila* (Dwarf Sumach), *R. viridiflora* (Green-flowered Sumach), *R. pentaphylla* (Five-leaved Sumach), *R. suaveolens* (Sweet-scented Sumach), and *R. aromatica* (Aromatic Sumach). There are also a great number grown in hothouses, many of which may probably bear exposure to the open air.

RHUS TOXICODENDRON (Trailing Poison-Oak, or Swamp-Sumach), a north-American shrub, possessed of peculiar properties. The leaves, which are trifoliate, thin, shining when fresh, of a dark-green colour, are the only parts officinal in this country. But the leaves, branches, and flowers contain a milky juice which blackens on exposure to the air, and may be used as an indelible ink when applied to cotton or linen. Besides this very acrid milk, the plant, when not exposed to the sun's rays, by growing in the shade, or during the night, exhales a hydrocarburetted gas, which acts very potently on persons of a peculiar susceptibility, when exposed to it. In two or three days after touching or being very near the plant, the skin inflames and swells, being attended with intense burning pain. If the face be affected, the eye-lids are so tumefied as to close up the eyes; and the whole head is swelled and covered with little blisters containing serum. Occasionally the whole body is enormously swollen and covered with similar vesicles. When the inflammation and swelling have subsided, the skin desquamates, and an intolerable itching is felt for several days afterwards. These symptoms closely resemble erysipelas, and are moderated by treatment suited to that complaint. Professor Barlow states that the best application is a weak aqueous solution of bichloride of mercury. All persons however should avoid touching any sumach which has milky juice.

The leaves, or an extract of the inspissated juice of this plant, have been recommended in several diseases, particularly herpes, paralysis, and consumption. It is little used in this country, but it appears entitled to some confidence in local paralysis, such as that of the jaw. It must be given with caution, as large doses act like narcotico-acrid poisons.

The bark of Rhus glabrum is said to furnish a most effectual means of checking salivation.

RHYME. Johnson's derives this word from the Greek *rhythmus* (ῥυθμὸς). Others derive it from the Swedish and Danish *rim*, the Dutch *rym*, and the German *reim*. All the principal European nations use the same word to signify the same thing. Thus, the French have *rime*, the Italians *rima*, and the Spaniards *rima*. The Greek and Roman poets did not use rhyme, and the word rhythmus was applied by both, in its poetical meaning, to the metrical arrangement of syllables, and not to the correspondence of sound in their terminations. Rhyme was not used either by the Celtic or by the early Scandinavian nations. Thus the Irish and Erse poems on which Macpherson founded his 'Poems of Ossian' are without rhymes, as is also the Scandinavian poem of the 'Lodbrokar Quida' (Lodbroc's Death-Song). Rhyme, as an accompaniment of verse, cannot be traced farther back among European nations than to the *rymours* of Normandy, the *troubadours* of Provence, the *minnesingers* of Germany, and the monks, who, after the fall of the Roman empire, added rhyming terminations to the Latin metres which were chanted or sung in the church service. Rhyme was early employed by the Italian poets. The 'Divina Commedia' of Dante, the oldest of the great Italian poems, is in alternate rhymes. The early Spanish ballads sometimes have rhymes, sometimes only assonances [ASSONANCE], and sometimes, as in the old Spanish romance of 'The Cid,' are without either rhyme or assonance. The early Anglo-Saxon poetry is without rhyme, but it is sometimes used in the later. All the old English poetry has rhymes, which are rude and imperfect, like the versification, but they are obviously an adjunct to the verse which could not be omitted.

Perfect rhymes arise from the identity of sound with which different words terminate—the identity, not the similarity. In monosyllables, or words which have the accent on the last syllable, to constitute a perfect rhyme it is necessary that the sound of the last accented vowel and of any letters which may follow it should be exactly the same as those of the word with which it rhymes. The sounds which precede the last accented vowel must be different in the two words. The spelling is of no consequence; the rhyme is in the sounds, not in the conventional signs by which the sounds are expressed. Thus *no* rhymes to *so*, but not to *do*, which rhymes to *too* or *two; great* rhymes to *hate*, but not to *heat*, which rhymes to *fleet;* and so on. If the sounds of the last vowels or of any of the following consonants differ in any degree, however small, the rhyme is so far imperfect; thus, *love* and *move* form an imperfect rhyme, the sound of the *o* in love being not only shorter than that of the *o* in move, but to a certain extent different. These monosyllable or last-syllable rhymes are called male rhymes.

Another class of rhymes is formed from words in which the accent is on the last syllable but one. In this class it is requisite that the sounds of the last vowel in the last syllable but one and of all the following letters should be the same as those with which they rhyme. Thus *desiring* and *respiring*, *descended* and *extended*, are perfect rhymes of this class. These are called female rhymes.

The principle of rhyming, once understood, the application is easy in all cases. Thus, if the accent is on the last syllable but two, the sound of the last vowel of the last syllable but two, and of all the following letters, must be the same. Thus, *sensible* and *extensible* are perfect rhymes of this class; but *dissolute* and *resolute* are imperfect rhymes, the vowels in the last syllable but two of both words having different sounds.

The same principle of rhyming applies to all the modern languages, as well as to the English. Imperfect rhymes are more or less freely used in all of them according to circumstances. The English and German languages, which abound in consonants, and have for the most part consonant terminations, are more deficient in rhymes than the Italian and Spanish, which abound in vowels, and have for the most part vowel terminations.

The English use blank verse as well as rhyme in the ten-syllable measure, but they have not been successful in the omission of rhyme in any other of their forms of verse. There have indeed been a few attempts in lyric measures, of which Collins's 'Ode to Evening' and Southey's romantic poem of 'Thalaba,' may be taken as favourable specimens. The Germans have been more successful in their unrhymed lyrics. The Italians and Spaniards have lyric measures of all kinds, both with and without rhymes. The French have been quite unsuccessful in their attempts to introduce blank verse in any of their measures.

RHYNCHÆA. [SCOLOPACIDÆ.]

RHYNCHASPIS. [DUCKS, vol. ix., p. 178.]

RHYTHM. [ORATORY.]

RHYTHM (Ῥυθμός, *measure, proportion*), in Music, is *Time;* first, in a limited sense, as in the relative proportions of notes in a single bar; and, secondly, in a more general sense, as in the relative proportion of a number of bars in any given portion of a composition, as in either half of a minuet or of a march. Rhythm is the most important constituent of music; without it inarticulate sounds are unproductive of any musical effect. [MUSIC, p. 20, col. 2.] In melody, that is, a succession of measured sounds, notes are the component parts of a bar, and bars are the component parts of a strain, or musical period, or phrase. The due relative proportion of all these is absolutely necessary in the formation of a good musical composition; without it, says one who seems to have possessed a most discriminating and refined taste in the art,—

> 'How sour sweet music is
> When time is broke, and no proportion kept!'
> *Richard II.*

Musical *Rhythm*, in its limited sense, divides a bar into 2, 4, 8, &c. or 3, 6, 12, &c. equal parts; the former is *binary* measure, the latter *ternary*. In its more general sense it divides a strain, a phrase, or by whatever name the subdivisions of a composition may be designated, into equal portions of 2 or 4, &c. or 3, 6, &c. bars, or measures; but some writers have admitted a rhythmus of five bars. An intimate acquaintance with the nature of rhythm, whether considered in its relation to music or poetry, is essential to the accomplished composer; without a full knowledge of this he is perplexed by doubts, and guilty of errors which have too often brought reproaches on the art, which they ought to have fallen on the pseudo-artist. Our limits however will not allow us to extend this article; and we refer the reader, particularly the professional one, to a learned and able disquisition on rhythm in Burney's 'Hist.' vol. i., p. 71; to Callcott's 'Musical Grammar,' where much practical information from Riepel and other German writers is to be found; to Kollman on 'Harmony;' and more especially to Reicha's 'Traité de Mélodie,' second edition, Paris, 1832, a very luminous work, the production of a highly-informed, deep thinking, and truly scientific musician. [PHRASE; TIME.]

RIASAN, or RJASAN (sometimes written *Rāsan*), is an extensive government of European Russia, which derives its name from the very antient town of Riasan, which indeed has long since fallen into ruins, but the name has been transferred to the town of Pereslawl. It is situated between 53° and 55° 40′ N. lat., and between 38° 18′ and 41° 30′ E. long., and is bounded on the north by Wladimir, on the east and south-east by Tambow, on the south-west by Tula, and on the north-west by Moskwa. The area is nearly 16,000 square miles, according to Reymann's map, which is followed by Hassel, Stein, Cannabich, and Schubert; but Hörschelmann and Köppen make it only 14,… square miles. The population, in 1838, was 1,241,000. It is divided into twelve circles. The country is traversed by many small hills and eminences, and the banks of the rivers are high. No large rivers run through it, but there are many smaller ones. The surface is diversified with large forests and groups of trees. It is only on the banks of the Don, the Osetr, and the Prona that the elevations are rocky; the other eminences consist of beds of stone, clay, marl, and lime, and are by no means unfruitful. The soil in general is a pretty thick layer of fine black mould. The wastes are susceptible of cultivation, but they are much neglected. The principal rivers are the Oka, which flows from the government of Moscow, and the Don, which issues from lake Iwanowskoe, on the frontier, both of which rivers receive smaller streams. The greater part of the canal is in this government, which joins the Bakowa, a tributary of the Prona, which flows into the Oka, and the Lernoi, which flows into the Woronesh, a tributary of the Don, thus making a communication between the Wolga and the Don by the Oka and the Woronesh. But this canal seems to be of little use, because the above small rivers are not navigable by boats except in spring, when the water is high. There are no large lakes. In autumn, winter, and spring the weather is variable, and in summer hot. The climate is healthy.

The soil is on the whole very fertile, especially in the southern part, where it is drier than in the northern, which contains some morasses. Rye, wheat, oats, barley, millet, flax, and hemp are cultivated. There is not only sufficient corn for home consumption, including large quantities used in the distilleries, but even in moderately productive years a considerable surplus for exportation. Horticulture is very general; every peasant has his kitchen-garden, where all kinds of Russian culinary vegetables are grown, especially cabbages, which in some seasons weigh from 25 to 40 pounds. Most of the peasants grow hops, which are an article of exportation. Apples and cherries are the fruits chiefly cultivated. There is sufficient wood in the southern parts, and abundance in the northern circles. On the banks of the rivers there are meadows covered with the most nutritious grasses, and good pasturage in the forests. In the plains or wastes too there are large tracts very well suited for sheep-walks. The breeding of cattle might therefore be more extensively carried on than it is; but the farmers let their pasture-land to the cattle-dealers of the Ukraine. A farmer has generally two or three horses, three or four cows, and five to ten Circassian sheep. Few swine are kept, and no domestic poultry except the common barn-door fowl. Bees are very generally kept. Fish abound in the rivers, and great quantities are exported. There is little game of any kind, but the number of quails is remarkable; many thousands are killed in the autumn, which are salted, and sent in small barrels to all parts of the empire. The minerals are iron-stone, clay, marl, lime, a little free-stone, gypsum, vitriol, and sulphur.

There are few manufactures of any importance, and those chiefly in the towns. The country-people spin thread and worsted yarn, and manufacture coarse linen and woollen cloths, leather in considerable quantities, wooden agricultural and domestic implements and utensils, and bast shoes. The brandy distilleries are numerous. The exports of the government consist in the surplus of its natural productions, and of its manufactures, especially leather. Almost all the exports go to Moscow, from which it receives in return such articles as it has need of, except salt, which it obtains from the banks of the Wolga.

The inhabitants are all Russians, except a small number of Mordwins, who live in a few villages, and between 3000 and 4000 Tartars, who live partly in the town of Kasimow, and partly in some villages. The archbishop of Riasan and Saraisk is at the head of the Greek clergy. He has 6 monasteries and 831 parishes under him. The Mohammedan Tartars have their imams, mosques, and teachers.

RIASAN, the capital of the government (formerly called *Pereslawl Riasanskoi*), in 54° 52′ N. lat. and 39° 20′ E. long., is situated on the river Trubesch (a branch of the Oka) at its junction with the Lebeda. It is a well built town, not fortified, but only surrounded with palisades. It is the residence of the military governor of Riasan and Tambow, of the civil governor and the government authorities, the see of the archbishop, and has a seminary for priests, a gymnasium, 30 churches, and manufactories of woollen cloth, linen, sailcloth, leather, glass, and iron-wares and needles. There are about 9000 inhabitants.

Saraisk on the Ossetr has 5000 inhabitants, 8 churches, and a great trade in cattle. Kasimow on the Oka and the Babinka, has 10,000 inhabitants, of whom 300 are Mohammedan Tartars, who carry on a great trade in furs.

RIBALTA, FRANCISCO, was born at Castellon de la Plana in the kingdom of Valencia in Spain, 1551. It is thought by some that he at first formed his style by studying the works of Juan Bautista Juanes, whose works adorn many of the churches at Valencia, and some of his pictures appear to favour that position. But he subsequently visited Italy, where he resided some years, and there seems to have acquired a taste for the style of Sebastian del Piombo, of many of whose pictures, in the royal collection at Madrid, he made copies, three of which are in the convent of the Carmelites in that city. In an inscription on one of these pictures in the hospital of Montserrate at Madrid, he calls himself the translator of Sebastian:

'[illegible]
[illegible]'

He died at Valencia in 1628, aged 77. His best works are at Valencia.

RIBALTA, JUAN, son of the above, was born at Valencia in 1597. He was the pupil of his father, and in his eighteenth year painted a picture of the Crucifixion, which is still considered among the master pieces of the Spanish school. He would probably have attained the highest eminence in his art, had he not been cut off in the flower of his age. He died in the same year as his father (1628), in the 31st year of his age.

RIBAND, or, according to the common orthography, RIBBON, signifies a long narrow web of silk worn for ornament and use. Ribbons of linen, worsted, gold, or silver thread were formerly included in the term, but it is now generally confined to those made of silk. Johnson derives the word from the French *ruban* or *riban*, which Skinner, in his 'Etym. Ling. Angl.,' imagines to be formed from the Latin particle *re* and the Saxon *bind* or *bande*, thus meaning to double or tie back. According to others, it is derived from *rouge*, red, and *bande*. Alfonso XI., king of Castile, instituted in 1332, for the younger sons of noble houses, the *order of the Band*, which was a *red* ribbon worn over the *right* shoulder and under the left arm of the knight. The word *band* is common to all the Teutonic languages; whether allied in its origin to the low Latin *bandum* (an ensign), the Cambro-Britannic *baner* (a standard), or to the Saxon *bend* (anything that binds), is disputed. Ribbon, in German, is *band*; Danish, *baand*; Swedish, *band*; Dutch, *lint*; Russian, *lenta*; Spanish, *cinta*; Portuguese, *fita di seda*, from the Latin *vitta*; Italian, *del nastro*, *fettuccia*.

Webster maintains that 'ribbon' has no connexion with *band*, but that it is of Welsh origin, from *rhibin*, a row or streak; Irish, *ruibin*; Armoric, *rubanen*; French, *ruban*. Conformably with this opinion, he writes the word *ribin* in his 'Dictionary,' a mode of writing which represents the vulgar pronunciation as well as that of Sheridan—*ribbin*. Chaucer, in the fourteenth century, speaks of 'ribaninges,' meaning apparently borders.

Whether, in its origin, the name of ribbon were a *banner* or a *band*, or neither, the ribbon has served in the cause of both love and war in its subsequent history:

> 'Yes, in the lists they wait the tourney's sound,
> Some love device is wrought on every wound,
> And every ribbon bears some mystic word.'—*Granville.*

The knight went forth 'to do or die,' strong in the badge of scarf or ribbon received from his ladye love, which, twined in a true-love knot, it cherished her constancy at home. The village swain buys a ribbon at the fair to adorn his sweetheart's rosy cheek; the young recruit walks proudly under the gay-coloured knot fastened to his ploughman's hat; and the veteran commander arrays himself in the ribbons of his orders. The white ribbon wedding-favour is the emblem of innocence and happiness, while a green, a blue, or an orange cockade is the herald of strife to a town, a county, or a nation.*

There can be no doubt that silk was early wrought into ribbons, and that they formed a branch of the silk manufacture during its progress from Greece to Sicily, and from thence to Italy and Spain; but the ribbon trade seems first to have assumed distinct importance in France. Louis XI. is supposed to have made the first successful attempt to produce silk in his kingdom; he planted mulberry-trees, and in 1480 settled some Italian silk workmen at Tours. Under Francis I. and Henri IV. the manufacture advanced rapidly. It was established at Lyon by the former in 1521, by means of some Milanese artisans, whom he prevailed upon to fix themselves there under his patronage; by the latter monarch it was established at Paris, and, amongst other encouragements, he promised patents of nobility to such of the manufacturers as should have persevered in it for twelve years. 'France, until this time,' observes the 'Encycl. Méthod.,' 'was an agricultural and commercial nation; since then the silk manufacture has contributed to extend both the one and the other.'

Paris, Tours, Lyon, and Avignon were the chief seats of the ribbon trade; the two last cities were rivals until the year 1720, when, partly owing to the regulations which the jealous Lyonnese had prevailed upon the government to make in their favour, and partly to a plague of two years' continuance, the trade of Avignon was ruined, and in great measure transferred to Lyon. At Paris the master ribbon-weavers were incorporated into a company, under the designation of *tissutiers rubaniers* of the town and suburbs of Paris: they were also styled, together with the makers of gold and silver ribbons and galloons, fringes, bordeings, &c., *ouvriers de la petite navette* (shuttle), in contradistinction to the makers of broad stuffs of gold, silver, and silk, who

* By an act 7 & 8 Geo. IV., c. 37, candidates at elections are forbidden to give ribands or cockades or any distinctive marks to their voters, under a penalty of 10l.

were entitled *ouvriers de la grande navette*. Figured ribbons were made chiefly at Paris. The 'Encyclopédie des Sciences,' &c. states that, about the year 1680, there was a rage for ribbons *gauffrés*, or embossed, on account of their novelty. The stamping was performed by hot plates of steel, on which a pattern was engraved, being applied successively along the piece. A master-weaver named Chandelier, tired of this slow process, contrived a machine which would save his trouble. He engraved his figures on two cylinders of steel, between which, when heated, the ribbon was compressed and drawn rapidly by a simple machinery, so that a piece of ribbon was embossed in less time than his brother-workmen consumed over a single ell. 'The genius and invention of this weaver had their recompense —these ribbons *gauffrés* made his fortune.'

The ribbons called *double lisse*, (double warp) which were considered the richest and best, were made at Tours. Before the revocation of the Edict of Nantes, the ribbon-looms of Tours amounted to 3000; but this measure, which banished the Protestants, banished with them their trade, and both Tours and Lyon suffered severely from its effects; the trade of Lyon afterwards revived. Savary, inspector-general of French manufactures, in his 'Dictionary,' published in 1723, says, that the trade in ribbons was much diminished in his time: he also remarks—'It may seem strange that in London, where they excel in this sort of fabric, they give the preference to the Parisian ribbons, while at Paris, as if in compensation, there is a sort of rage for the English, although those of Paris are not very inferior.' This was likewise the case at the time when the importation of ribbons was prohibited in both countries—an instructive commentary on the wisdom of such prohibitions—although, some time previous to the date of the first edition of the 'Dict.,' English ribbons were admitted on paying a duty of 4 francs per lb. In the 'Encycl. des Sciences, &c.,' published in 1765, there is the same complaint of the decline of the ribbon manufacture in France, but still the consumption was large, and large quantities were exported. In the enumeration of the different kinds of ribbon, a double satin is mentioned, that is, one alike on both sides in texture, although sometimes of different colours.

The 'Encycl. Méthodique' (1784) estimates the number of French looms employed in ribbons, galloons, &c. at 12,000, and gives the following amongst other information on the subject:—The ribbon manufacturers bought their silk already dyed. The price of the dyed Italian organzine was from 52 to 57 livres per lb. of 15 ozs.; of tram, from 30 to 40 ditto. The wages of the engine-loom weaver were from 40 and 50 sous to 3 livres per day. The kind of ribbon called *ruban Anglois* was composed of organzine warp and China shoot, both of fine quality. These ribbons, being light in texture and dressed with care, possessed a brilliancy which caused them to be much in favour. The ribbons of Paris were then esteemed the best in make, but Lyon, with its neighbours St. Etienne and St. Chamond, supplied the largest quantity. The chief markets for the best qualities were Francfort, Leipzig, Lübeck, Petersburg, and England, notwithstanding the prohibition; for the inferior, Italy and Spain. Figured ribbons were made in Flanders, the Lower Rhine, Germany, and Switzerland. Ribbons formed the principal commerce of Basel; many of the Swiss ribbons, though inferior, were sold for those of St. Etienne when the demand at that place exceeded the supply. Plain ribbons were made largely in Spain, at Saragoza, Seville, Murcia, Granada, &c., and brocaded at Valencia. In speaking of Lyon, this writer observes, 'that by the novelty, freshness, and elegance of its designs, it has long held and will long continue to hold the empire of taste. It has originated the most ingenious machines to facilitate the operations of its arts, and from thence have they been carried out over the world. The manufactures of Switzerland, Germany, Spain, and even of Petersburg, were set on foot by Lyonnese or by apprentices from them. The English alone appear to owe us nothing on this score. They have invented, copied, or imitated almost all kinds of silk goods, and if they do not always equal the French taste and delicacy, they keep up the qualities with a steadiness which results from the employment by the manufacturer always of the same material for the same purpose, and from the keeping of the workman always to the making of the same kind of fabric.'

The making of ribbons and small articles in silk long preceded in England that of broad silk. The trade was principally in the hands of women; and, like a sickly plant of foreign growth, it appears to have constantly demanded props and support. In the reign of Edward III., an act was passed to prevent artificers from using more than one trade or mystery, the silk-women and other female artificers being exempted from its operation. In the same year, 1364, an enactment was made for the regulation of apparel, by which none under the degree of esquires of 200*l.* of yearly rent, and their ladies, with some few exceptions, were permitted to wear stuff of silk, silver, ribbons, girdles, or furs. By an act of Henry VI., nearly one hundred years later, 'for the encouragement of silkwomen and throwsters,' it was forbidden to import wrought silk, ribbons, laces, &c., under a penalty of 5*l.*, the act to continue in force for five years. This was renewed in the third year of Edward IV., with a sort of apology, which, if good for anything, made the prohibition unnecessary. The act states that not only were the artificers, men and women, 'greatly impoverished, hindered of their worldly increase and daily living, by these wares and chaffres being brought in fully wrought and ready for sale by strangers, the king's enemies, and other,' but that 'the greatest part in substance was deceitful, and nothing worth in regard of any man's occupation and profit.'

The next sumptuary act forbids the wearing of silk by persons not possessing more than 40*l.* per annum. The increased consumption of silk is shown in the lowered qualification, and at the same time a striking proof is given of the shortsightedness of legislative interference on such points; with one hand the government strove to hold up the trade by shutting out foreign supply, with the other to check the home demand. By acts passed in the first and second years of Philip and Mary, the lower classes and servants, upon whom it appears the prohibition had now descended, were forbidden to wear silk on hat or bonnet, &c., under pain of imprisonment for three months and forfeiture of 1

The law against the importation of ribbons, &c. was renewed at successive intervals until the 19 Henry VII when it was made perpetual. Foreign ribbons notwithstanding still made their way over, and we find another attempt to check the trade in an order of Charles I., which forbids any silks to be imported under the breadth of … nails and a half. A proclamation of this king in … furnishes us with another example of the blunders that legislation is apt to make in such matters:—'Seeing that the silk trade was enlarged to the enriching of the kingdom, and setting many thousand people to work, unless … deceitful handling thereof do bring the same into discredit and thereby deprive the land of so hopeful a trade which hath near attained the perfection thereof, and whereas hath lately been discovered that a notable abuse hath crept in by adding to the weight of the silk in dyeing, it is commanded that no dyer should henceforth, now or at any future time, use any slip or alder-bark, or iron-filings … no silk be dyed of any black but Spanish black, and that the gum shall be fair boiled off before dyeing.' But however afterwards 'better informed,' and finding … taffeties, some kinds of ribbons, and other articles required to be made of hard silk, or silk dyed upon the gum, … part of the ordinance was rescinded, in a subsequent proclamation dated 1638. (Rymer's *Fœdera.*)

The silk-throwsters were incorporated by a charter obtained 5 Charles I., about ten years after the establishment of the broad-silk manufacture, in the reign of James I. … silk-weavers were already included in the great company of weavers. Towards the end of the reign of Charles II., … silk manufacture, which had hitherto been almost confined to London, was carried into several other large towns of … kingdom by the French Protestants, who took refuge in … country, to the number, it is said, of 70,000, after the revocation of the Edict of Nantes in 1685, and amongst them … to Coventry. Camden tells us that 'the wealth of Coventry arising in the last age from the woollen and cap manufacture made it the only mart of this part, and … resorted to than could be expected from its midland situation.' The ribbon trade, of which it has since become … chief seat in England, was introduced early in the last century by Mr. Bird, assisted probably by some of the French emigrants: the number of French terms still used in … manufacture proves that its origin was, in part at least, foreign.

After the treaty of Utrecht, in 1713, French and Italian manufactured silks were admitted under considerable duties, but in 1765 the ribbon and other silk manufacturers procured the re-establishment of the prohibitory system, wh…

was thenceforward maintained for sixty years, enforced by heavy penalties. With the increase of population and the greater demand for luxuries, the home market increased; but an export trade, principally to America, gradually decayed, in consequence perhaps of the heavy duties on raw and thrown silk. During this period of restriction, ribbon-weaving seems to have degenerated in this country as regards the superior branches. In a petition to parliament from the Weavers' Company, in 1713, against the commercial treaty with France, it is asserted that the English ribbons were as good as those of the French. It was stated by a Coventry manufacturer to the Commons' Committee on the Silk Trade, in 1832, that he had seen 'patterns of ribbons made from fifty to a hundred years ago in England, wider, richer, and of larger figure than were made just prior to the introduction of French ribbons in 1826.' (Question 866.) Most of the specimens adduced by the Spitalfields manufacturers who were then examined in proof of their assertion that our silk-weaving needed no instruction from French patterns, were of a like early date. On this occasion it was generally assumed that English ribbons were inferior to French. Recollecting also the observation of the French writer, at a time still farther back, 'that the Parisian ribbons were not very inferior to the English,' we are led to ask why English industry and skill have not in this instance maintained their accustomed superiority, and to suspect that they have been repressed rather than stimulated by the system of prohibition.

In 1824 the government determined to try the effect of an approach to free trade upon the silk manufacture. As a preliminary step, the duties on raw silk were reduced from 3*s*. per lb. to 3*d*., and afterwards to 1*d*.; and on thrown, from 14*s*. 8*d*. to 7*s*. 6*d*., and afterwards to 3*s*. 6*d*., 2*s*., and 1*s*. 6*d*., according to quality, with a drawback to the amount of the duty allowed on any manufactures of silk exported, whether they were or were not made of the foreign thrown silk which had paid the duty. Two years were allowed after the lowering of these duties to prepare for the admission of foreign manufactured silk at a duty of 30 per cent. During this interval the reduced price of silk stimulated the Coventry trade; the market was brisk; considerable capital was embarked to meet the increased demand, even in those branches which would inevitably suffer the most from French competition, and consequently an accession of hands was drawn into the manufacture. There were 5 Jacquard looms in Coventry in 1823; in 1832 the number had increased to 600. This period of two years was virtually prolonged for one or two more, by an exclusion of the goods prepared for our market in 1826, in consequence of an after regulation which required the pieces to be of the English lengths. As those differ from the French, the full force of foreign competition was not felt until 1828. A reaction then took place in Coventry as elsewhere; deep and loud were the complaints of masters and workmen, and the distress among the latter was great.

Besides the shock which the change even from a worse to a better system must occasion, unless prepared for by all parties with extraordinary prudence and foresight, and besides the vicissitudes to which all trades are subject, that of ribbons is peculiarly liable to fluctuation from the caprice of fashion. A demand suddenly arises, continues for one, two, or more seasons, and requires the employment of many new hands; it ceases as suddenly, and they are thrown out of employ. Wages are reduced, starvation threatens the workman, and it is not surprising that he should petition that his labour may again be rendered available by shutting out that of others abroad or at home.*

A Committee of the Commons was appointed in 1832 to inquire into the state of the silk-trade, at which such of the leading ribbon manufacturers as disapproved of the late measure, and also some of the weavers, attended. They were unanimous in demanding a total prohibition. 'Nothing short of this could enable them to make ribbons at all.' (Qu. 1844.) 'The inveterate *prejudice* in favour of French fancy ribbons made nugatory the protecting duty; it was not a matter of 'price, but of fashion.' (Qu. 2420, 2495.)

* Note. 'It was estimated, before the admission of French goods, that the number of hands then in the trade could have produced in nine months, if fully employed, the whole of the year's sales of Coventry manufacturers, and this permanent excess of hands was aggravated to an 'awful depression' by the amount of French competition. During a slack time one-third or more of the single-hand looms, and a very large proportion of the engine-looms, especially those in the fancy trade, always have been out of work, but in this case it is not the *same* looms that are unemployed during the whole slack time.'—(J. Fletcher, Esq., *Report on the Hand-loom Weavers*.)

Smuggling, which had not even diminished since the legalised entrance of French goods, would in all probability increase under a renewal of restriction; but 'smuggling to a certain extent was beneficial, for it furnished the manufacturers with patterns.' (Qs. 447, 737, 738, 846.) With total prohibition then was demanded a more vigilant preventive service, and severe personal penalties on smuggling, whilst the hope was still entertained that after all ribbons enough would be smuggled to furnish patterns and styles. By this expensive apparatus the capitals embarked in the fancy trade *might* be protected, provided that the public, when they could not get their favourite French article, should not give up the use of fancy ribbons altogether. The duty was allowed to be a sufficient protection against the French plain ribbons, the English being so nearly equal to them in quality; and several of the manufacturers admitted that some improvement had taken place in the fancy goods since the entrance of their foreign rivals. The partner of a London house largely concerned in the trade asserted that this improvement was very considerable, and that the stimulus of foreign competition was required. It was conceded by one of the manufacturers in his evidence, that although patterns had been obtained by smuggling before the removal of the prohibition, they had formed no idea until then of the extent of the French manufacture, nor of the style and fashion that would be introduced. (Qu. 803.)

This inquiry led to no alteration in the system which the government had adopted, and two further remonstrances made by the same parties in 1833 and 1834 had a similar result.

That France possesses some advantages over us in this peculiar fabric is undoubted. These advantages consist in the superior cultivation of taste—even the weavers may be seen arranging the flowers of a nosegay, so as to produce the most beautiful combinations—in the growth of its own silk, some of which, from the Cevennes, is the finest in the world from its peculiar brilliancy; and in the cheapness of labour, the cost of which is on an average about half that of the English. In their gauze ribbons these advantages unite with peculiar effect; the fine white silk, the exportation of which is not allowed, the greater proportion in them of labour to material, and the elegant variety of which they are susceptible, constitute them, in the words of the English weavers, 'a more natural manufacture of France, as hardware and cottons are a more natural manufacture of England.' It appears just that these advantages should exchange with each other, and it must not be forgotten that these gauzes must be paid for by British labour in some shape or other.

The English throwsters in 1817 petitioned the government to take off the duties on raw silk, in the expectation of exporting thrown silk, as this country now exports cotton yarn. Mr. Doxat gives it as his opinion that the throwster in England does his work cheaper, relatively, than in France or Italy, and has the command of a greater variety of silk. It appears from the evidence of Dr. Bowring, laid before the committee of 1832, that the French themselves expect that, from the superior capital and machinery of our throwsters, English thrown silk will soon be imported into France. He also states that the impression in France was so strong that the English silk fabrics had greatly improved since 1826, that considerable alarm was felt on the subject, and a high authority at Lyon expressed his belief that it would be better to prohibit the export of silk goods to England. English silks are not now prohibited in France, as they formerly were, and upon the whole the silk manufacture has been less 'protected' there than almost any other, and it appears to have prospered partly for this reason; all foreign silks are admitted into France at a duty of from 13 to 15 per cent. The importation of English manufactured silk into France was in 1828 to the amount of 4699*l*.; in 1830, 24,810*l*.; in 1838, 56,598*l*.

According to Dr. Bowring, in 1831, the number of ribbon manufacturers at St. Etienne and St. Chamond was 200. The number of ribbon looms in these towns and the surrounding district, which in 1812 was 9000, had increased to 23,000. Their daily produce was 350,000 ells. There are three kinds of looms in use: 1st, the old unimproved single-hand looms called *basselisse*, employed for plain satins and sarsnets; they were 18,000 in number, and are used by weavers who engage themselves in agriculture when there are 'no orders' in the town. 2nd, the single-hand loom called *hautelisse*, generally applied to produce large patterns;

of these there were 500, 100 having the Jacquard machinery attached. 3rd, the *à-la-bar*, or *bar loom*, 5000 in number, of which 800 were employed in sarsnets, 200 in velvets, 700 sarsnet galloons, 800 stout and light satin, 2000 Jacquard, and 500 striped gauzes. Two-thirds only of these were actually employed. The proprietor of the looms, who receives the work from the manufacturer, is called the *passementier;* he gives half the price paid for the weaving to the *ouvrier*, who is the weaver. The lowest daily earnings of the last were equal to about 1*s.*, the highest to 3*s.* 8*d.* There is a list of prices for weaving agreed upon amongst the manufacturers of St. Etienne, as there is at Coventry. Goods are not made on speculation, the trade being conducted by orders.

At Lyon a recent contrivance, by which the broad-silk loom had been made applicable to ribbon-weaving, had brought back a portion of the trade which had almost deserted it. By the introduction of 4 small shuttles instead of one, 4 pieces of ribbon were woven at once. There were 800 or 900 looms, chiefly Jacquard, and from 30 to 40 single-hand employed for the richest goods. The value of the French ribbons exported in 1831 was about 936,945*l.*, of which England took 75,147*l.*, the United States 472,678*l.* The whole annual value of the ribbons manufactured in France in 1832 was estimated by Mr. Dillon, in his evidence before the silk committee, at 1,300,000*l.*; in England, from 800,000*l.* to 1,000,000*l.*

The Swiss exchange their inferior ribbons for the superior ones of the French; their sarsnets are now superior to those of St. Etienne. They have an advantage in the manufacture, as they pay no duty on the silk, and the manufacturer is generally his own importer, throwster, and dyer. There were about 3200 looms at Basel in 1831, principally for plain goods. Switzerland is entirely free from protective duties. (Dr. Bowring.) Large quantities of Swiss ribbons came in on the opening of our trade, but they could not enter into competition with the English in quality or price, the cost of transport being considerable.

At the present time there are few if any ribbons made at Lyon; many of the looms which had been converted into ribbon-looms being now employed in weaving shawls.

The silk manufacture was established in Dublin about the same time as at Spitalfields by the French Protestants. Ribbons were made there in considerable quantities. In 1824 the number of ribbon engine-looms amounted to 996. The trade seems to have laboured under still greater inherent disadvantages than that of the English, one of which was that the price of silk was enhanced to the manufacturer by the additional charges consequent upon its transmission through London. When exposed to British competition by the withdrawal of the protecting duties which existed before the Union, and soon after to that of the French also, the trade sunk beneath the shock, and is now almost annihilated, a fact which proves that its growth was unsound and premature. The influx of the distressed Irish silk-weavers to Coventry, Macclesfield, and other places increased the number of unemployed hands in those towns. The Irish manufacturers made precisely the same remonstrances against the free admission of English silks which those of England did against the importation of the French. (Commons' Committee, 1832.)

After a period of ten years the result of French competition appears to be this—an increase in the consumption of ribbons altogether owing to the beauty and taste of the French ribbons. These create the fashion and supply the highest market, while Coventry has a collateral trade among the middle and lower classes, which extends with the other. This is proved by the fact that although the importation of French ribbons has increased with the increasing acquaintance of the foreign manufacturer with the English market, the number of looms has augmented in Coventry; in 1838 more ribbons were made there than in any one year before. At the close of the last war, when an extraordinary demand for ribbons with large pearl edges had occasioned a sudden extension of the trade, the number of looms in Coventry and the surrounding parishes was 8491; in the year 1838 the number was 13,239, nearly all of which were employed. The real increase in the number is greater than at first sight appears, owing to the larger proportion of engine-looms, which make several pieces at once, to the single-hand. The quantity of silk dyed in 1827 was 339,956 lbs.; in 1837, 451,110 lbs. The fashion, which in 1837 was in favour of gauze ribbons, had exchanged them for a heavier style of goods, and many ribbons were produced in Coventry which equalled in quality their foreign rivals of the same make.* The anxiety to procure French fabrics merely as French has diminished since they became more comm... A purchaser asks less often than formerly 'is it French or English?' and if the question be put, it not unfrequently happens that an article is termed either the one or the other to meet the wishes of the customer, so slight is the appreciable difference. Some of the Coventry manufacturers are also importers of French ribbons. Mr. Fletcher states, in his Report on the Handloom Weavers, 'that neither the weavers nor the master manufacturers generally mentioned prohibition as a remedy to which they now ... claim.' The masters demand chiefly better regulations concerning the levying of the duty, which, from the want of a custom-house officer acquainted with the ribbon trade, is done with great inexactness, some goods paying more than, and others scarcely half, the legal amount of duty; and that smuggling should be punished by personal penalty rather than by fine; for 'as smuggling is now carried on by a few large capitalists, who calculate the risk of fine in ... charges, instead of by petty coasting traders, as was the case under the system of total abolition, the punishment by fine affords scarcely any protection. The cost of smuggling in 1830 was reckoned at about 20 per cent.†

Originality is at present very little attempted in patterns; they are in general mere copies of the French or recombinations from them. There are a few artists and superior weavers engaged in preparing them, but their remuneration is trifling. A drawing-class at the Mechanics' Institution, London, has had some effect in developing a taste for design among its members; and a School of Design, supported by national funds, has existed for more than two years in London, under the superintendence of government.

The ribbon manufacturers of Coventry are about 130 in number, including about 40 'first-hand journey-hands' who own their looms and work them on their own account. These employ nearly all the hands of the district. The leaders of the trade are not, as formerly, the manufacturers, but the 16 or 18 London and Manchester houses through whom the ribbons are distributed to the retailers. The buyers attend at Coventry regularly, many of them once a week; according to the demand, they give orders or purchase from the stocks already made. To keep his hands together the manufacturer is obliged to give work even when trade is flat; his stock therefore continually accumulates; if of fancy goods, it must be sold while fashion favours the demand, or kept at the risk of loss; if of plain goods, they are held with the chance of fluctuation in value as the price of silk rises or falls. A reduction in the price of weaving would depreciate the value of the stock in hand; the manufacturer has therefore ... an interest in keeping up the rate of labour. Formerly the same price was always given for the same labour, so that from the depression of trade this was too high for the pr... the manufacturer gave out no work at all, but when the system of trade was changed by the competition of the ... warehousemen, and the excess of hands increased, numbers were glad to obtain work on any terms. This led to a general reduction of wages; the larger manufacturers and the weavers struggled ineffectually to maintain an equ... of the prices of weaving by voluntary co-operation in the trade, and they attempted in 1818 to procure the extension of the Spitalfields' Act for the regulation of the silk weavers' wages by the magistrates, from London and Dublin to Coventry. The evidence however adduced upon this occasion led to the repeal of the act altogether in 1824. M...

* The best ribbons made in France are those prepared for the English market; the home consumption is chiefly of less costly goods.

† The cost of smuggling is now (1840) rated at from 10 to 15 per cent. ... proportion of French silk goods smuggled into England to those registered, between the years 1827 and 1838, varies from 36 per cent. ... cent. per annum. ('Report of the Select Committee of the Commons ... Import Duties,' August, 1840.) Since the above remarks on French ... tion were written, this Report has appeared, and is strongly corroborative of them. It must not be forgotten that the impolicy of prohibiting ... branch of trade applies to all. It is not surprising that, when the manufacturer, upon every successive reduction, represents to the weaver that ... are lowered because French ribbons are admitted, he should believe ... is the cause of the evil which oppresses him, and that he cannot see ... must make cheap ribbons, he may not be permitted to have ... The winter of 1839-40 was a season of considerable distress at Coventry ... a change of fashion, added to the general depression of the manuf... terest. The ribbon manufacture of England has sufficient difficulties to encounter in its rivalship with the French, to require the aid of the ... *mate* protection—an unrestricted interchange of its productions ... necessaries of life in the markets of the world.

efforts were subsequently made in Coventry to establish a list of prices to which all should conform, but the competition with France, with steam-power, and the interests of the trade continually caused its infraction, and since 1833 there has been no fixed regulation of prices except in the plain sarsnet trade.

The weaving is done on several systems. The *undertaking system* applies now only to the single-hand trade in the country districts,—Bedworth, Nuneaton, Hartshill, &c. It is the same that the French have employed since the days of Colbert. According to this plan, the undertaker or master-weaver receives the silk dyed in the hank from the manufacturer, and returns it in finished ribbons to his order; all the intermediate operations being included in the price of weaving—two-thirds of this are paid to the journey-hand for his labour; three-fourths of the single-hand weavers are women, and nearly one-half of the remainder are youths under 20. Boys and girls are considered competent weavers at 16 or 17.

On the *journey-work system*, by which the great proportion of the engine-looms in Coventry and its neighbourhood are worked, the manufacturer gives the silk, already wound and warped, to the 'first-hand journeyman,' who is also the owner of the looms. The shoot silk is given in hank, for the winding of which the manufacturer allows 1d. per oz., besides the price for weaving, in which is included 'the filling,' or the winding of the shoot on the small revolving pins within the shuttles. About one-fourth of the hands employed on this system are women.

On the *hand-factory system* the manufacturer is the owner of the looms. The 'journey-hands' work them in the 'loom-shop' of the proprietor, who gets the winding and warping done at his own charge, leaving only the filling to the weaver, which is included in the price of his work, and is often done by very young children. This plan is adopted by many manufacturers of small capital, who, by personally superintending the work, and becoming in fact their own 'undertakers,' are enabled to economize to the utmost in the cost of production, while their hands are all reduced to the lowest condition of the weaver—the journey-hand, who supplies the labour, and has no property in the looms. A modern innovation, encouraged by the last system, is the employment of two hands to a loom, the one being occupied uninterruptedly in 'shooting down,' or passing the shuttle and making the ribbon; the other in 'picking up,' or fastening broken threads, picking out knots, &c. The perpetual 'shooting down' without the 'picking up,' which relieves the muscles, requires more than ordinary strength; besides which the weaver, being confined to the almost mechanical successive movements of his feet upon the treadles, one hand driving the shuttle, the other striking the shoot with the batten, is reduced from a skilled artisan to the mere moving power of a machine. The weavers therefore oppose this arrangement, although it is found that in light work a man of average strength, with his wife picking up for him, will get through nearly double the work of a single weaver, and thus save the difference between the value of his own labour and the cheaper labour of his wife.

On the *steam-factory system* the manufacturer gets every preparatory process done; and by the steam-power one half of the weaving process itself—the shooting down: all that is left to the weaver being the picking up and superintendence. The profitable application of steam-power to silk-weaving was long considered to be almost impossible, so large a portion of time being consumed in the handling and trimming of the silk, in proportion to the time that the loom is in motion, and a consequent waste of power. 'I despair,' said one of the Macclesfield manufacturers in 1832, 'of ever applying power-looms to silk.' (*Commons' Committee*, 1832; Qu. 11,494.)

A *steam factory* was built in Coventry in 1831, for the purpose of making the experiment on ribbons. It was burnt however during a disturbance relating to prices; and though the act was disclaimed by the weavers in general, the feeling amongst them was so strong against the employment of *automatic labour* whilst their own was superabundant, that the scheme was given up. Within a few years there were numerous steam-factories at work at Congleton, Leek, Derby, and other places, which made large quantities of plain ribbons, chiefly black sarsnets. The Coventry manufacturers, alarmed for the interests of their trade, formed, in 1836, a steam company, and erected a large factory, but difficulties arose as to the apportionment of the power among the different parties, and it has never yet been filled up for its original purpose. Another large factory was soon after built, and applied to the making of figured ribbons, but owing to the failure of the parties, the experiment was not fairly tested. The difficulties must be greater in the case of figured than of plain ribbons, because in them the unskilled labour, which the steam-power supplies, bears less proportion to the value of the article than in any other. One experiment on a smaller scale had some success. The steam factories of the north and of Derby have proved its advantage as applied to plain ribbons. At Congleton there were, in 1838, 254 power-looms engaged in the manufacture of plain black, a few black satin, and some plain coloured ribbons; at Leek there were 160 employed in the same way, and at Derby 253. In these each loom is tended by one pair of hands, which pick up and keep the machinery in order: the gain consists not in a more rapid motion of the shuttles, the delicacy of the materials not allowing of this, but in the shooting down being seldom interrupted during the picking up, as in hand-loom weaving; in the greater regularity of the fabric, the same number of shoots to the inch being uniformly maintained; and also in the addition of from one-fifth to one-third more shuttles for which one workman suffices, the loom being so constructed as to enable him to reach from the front over the batten to the warps behind. But when two pair of hands are required for one loom, as is the case with the Jacquard, one before the loom to tend the work, and one behind to pick up, the advantage is much lessened; the only chance of saving will be by the use of the best possible silk in order that few stoppages may occur. The goodness of the silk is plainly of much importance to the success of all steam-loom weaving. It is undoubtedly making great progress notwithstanding all disadvantages; at the present time (1840) the steam-factory at Coventry, which formerly failed, is again at work under the management of fresh parties, who are making both plain and fancy ribbons with a strong probability of ultimate success. The fine factory belonging to the Steam Company, which is now occupied by broad silk steam-looms, has one ribbon-loom at work; and in one other instance, in Coventry, Jacquard steam-looms are employed in making light figured ribbons with great precision and beauty, and in this case it is found that one man is able to tend the front and another the back of two looms. There can be little doubt that the time is approaching when steam will be the chief motive-power of the ribbon as of other manufacturing districts, and that the strength of English machinery will be called forth to enter into competition with French taste.

Raw Silk is the silk in its natural state when wound from the cocoon. It varies in fineness according to the number of cocoons reeled off at once to form one thread, the filaments of which are united by their viscid property. In the process of dyeing the gum is discharged more or less, and the fibres become loose and unfit for weaving; the raw silk is therefore manufactured first into *singles*, *tram*, or *organzine*. By *singles* is signified one of the reeled threads twisted. *Tram* (from the French *trame*, or 'shoot') is formed of two or more threads twisted together, and is used in weaving ribbons for the shoot or weft. *Organzine* is formed of two or more singles twisted together in a *contrary direction* from that of its component singles. *Marabout* is silk thrown twice, and is made from fine white silk from which the gum has not been boiled; that of the French is the best. This preparation of the silk is the business of the throwster, a word formed from the word 'throw,' in the obsolete sense of 'to twist, to twine.'

Italian organzine, either thrown in Italy or in England from Italian raw (and principally the last), is used for the warp of the best English ribbons. Bengal and China organzine for inferior qualities. China, Bengal, and Brusa (a Turkish silk, produced at Bursa or Brusa, in Asia Minor) singles, all English thrown, are used largely for shoot. Bengal cannot be used for fine colours. Marabout is used for gauzes.

There are four throwing-mills in the neighbourhood of Coventry, besides several small establishments where hand-machinery is employed, in which the raw silk purchased by the manufacturers is thrown. The silk is bought through the London brokers or the Coventry silkmen, at a credit of five months.

The dyeing is carried on by four houses in Coventry. When the silk is dyed *soft*, that is, when the gum is boiled off, it comes back from the dyer with a loss of four ounces out of sixteen in weight; when dyed *souple*, the gum being partly retained, it loses only one ounce and a half in sixteen. Inferior warp silk dyed black, and of dark colours, is sometimes *weighted*, notwithstanding the proclamation of King Charles, by an additional quantity of dye, or by a mixture of sugar to increase its apparent substance. The French dyeing is considered to possess little or no superiority over that of the English; their blacks are inferior.

The fineness of the silk is determined by the number of warp lengths, measuring seventy-two yards, in the ounce; fine warp silk, for instance, 'runs' about eight score threads to the ounce of that length. One ounce in twenty is allowed for waste in the manufacture of the silk into ribbons; for all over that quantity the undertaker, or journey-hand, is accountable. If the warp and shoot are delivered ready wound, a quarter of an ounce in twenty is allowed. The preparation of the silk by winding it from the hanks on bobbins, and then again winding it off from a sufficient number of these bobbins at once round a large revolving perpendicular reel, called the warping-frame, until the requisite length is obtained for the piece of silk or ribbon that is to be manufactured, and likewise the weaving process itself, are the same for the making of ribbons and for broad silk. The single-hand ribbon-loom differs in no essential respect from that used for any other fabric, except that its size and strength are proportional to the lighter material.

The *Dutch engine-loom* was introduced about seventy years ago. In this loom, instead of one piece of ribbon only, several are woven at once, four of the broadest width, or as many as twenty-four of the narrowest. Each warp has a separate shuttle. The batten extends across the whole width of the loom; the shuttles slide within grooves made in the batten; the driver is worked horizontally backwards and forwards by a handle. At each motion the shuttles are propelled by the cross bars of the driver across their proper warps in the corresponding direction. The loom is worked by the hands, and with treadles for the feet, like the single-hand. The stroke of the batten (from the French *battant*) is made with more precision than in the single-hand loom, by the interposition of blocks of wood fastened to the framework in front, which resist the batten at the proper point. The impulse of this stroke pushes back the finished ribbon, which is hung with a weight attached to the end over a pulley at the top of the frame, or wound on a roller, just enough to draw forwards the warp, which is similarly hung over a pulley, in order to receive the shuttle at the same point. Each warp has a separate reed or *sleigh* attached to a horizontal roller, over which it passes on descending from the pulley. The sleigh is an instrument like a comb (called by the French weavers *le peigne*), for keeping the threads separate. There are corresponding sleighs in the batten. The cost of a plain engine-loom for sarsenets is about 8*l*., for satins about 12*l*. The hire of one is about one shilling per week.

Steam-power is applied to the different ribbon-looms by the ordinary methods. Those worked by steam are generally larger than the hand-looms.

The *à-la-bar*, or *bar-loom*, was invented and introduced into St. Etienne by two Swiss brothers about sixty years ago. It has largely contributed to the prosperity of the place, but the brothers died in poverty and neglect. It is a hand power-loom worked by means of a long transverse handle or bar, which extends along the front of the loom, and is connected with wheels on each side, which communicate the motion. The shuttles are driven by means of a rack and pinion across the warps. The advantage of the bar-loom consists in the saving of labour by the intervention of mechanical means, instead of applying the human power direct to the usual operations of weaving. The original cost of these looms is considerable (from 80*l*. to 100*l*.), and they have been little used in Coventry. There are but about eight in the town, with the exception of several which are worked by steam in the factory above mentioned. At Battersea they are employed in weaving figured ribbons. In the bar-looms of St. Etienne from twenty-eight to thirty of the narrowest and from six to eight pieces of the broadest width are made at once: about eight ells of the former per day, and from three to four of the latter.

Several hand power-looms have been contrived and adopted, in all of which the requisite movements are performed by a combination of levers, springs, cranks, and wheels. In a factory at Kettering connected with a Coventry house, six looms are worked by one man by means of a wheel. In all these cases of course separate hands are required to superintend the weaving.

Figures on ribbons, as in other fabrics, are chiefly formed by omitting the regular crossing of the warp and shoot in such a manner that a difference of texture shall occur in the web so as to mark out any pattern. This is effected in the single-hand loom by a multiplication of treadles connected with the lisses by which the different portions of warp are alternately raised. Forty treadles have been sometimes required to form an intricate pattern. Small figures produced in this manner are called *leys*. To execute more complicated patterns, *tires* (from the French word *tirer*, to draw or pull) are used. Tires are cords hung over the top of the loom, and pulled by the hand as the figure may require: they work like the treadles, by raising the lisses, through the eyes of which are passed the threads which are to form the pattern. Small patterns are still largely made in the single-hand looms by means of treadles and tires. The French single-hand loom of this description is called *hautelisse*. This was the name of the loom used in weaving the best tapestry, in which the warp was stretched perpendicularly, and hence it came to be applied to other looms for weaving figures. The hautelisse looms of St. Etienne are now generally worked by a bar, as well as the engine-looms.

The production of a large pattern in the manner above described is difficult and tedious. Many skilful contrivances have been devised by weavers and others for facilitating the operation, and among others the draw-boy; but they were all superseded by the introduction of the Jacquard machine, said by some to have been originally invented by the Chinese; it was brought to England in 1820. By means of this most ingenious invention the lisses are raised in the required order for the formation of the pattern, by an apparatus affixed to the loom, enabling the weaver to produce with nearly the ease and rapidity of plain weaving, patterns which it would formerly have been almost impossible to execute. The 'numbers' (that is, the numbers of the needles which regulate the raising of the warp threads) of some of the machines at St. Etienne are as high as 1050, those of Coventry range from 250 to 600. The price of a Jacquard engine-loom for sarsenet figures is from 16*l*. to 20*l*., for satin figures from 20*l*. to 24*l*. The hire of one is 1*s*. 6*d*., and sometimes 2*s*. per week. The number of Jacquard machines in Coventry and the surrounding district in 1838 was 2228. The draughting of the patterns and stamping of the perforated cards is a separate business, which is done on the premises of the larger manufacturers. The Jacquard is capable of being applied to both the engine and single-hand loom; but as the same cards and machinery are required for one breadth in the single-hand, as for several breadths in the engine-loom, it is seldom attached to the former except for a few very rich goods.

The work is ordinarily given out in *sets of grosses*, consisting of two warps for each shuttle, each warp containing two pieces of 36 yards. The ribbons are cut out in pieces of 36 yards if they are of satin, and in half pieces of 18 yards if they are sarsenets or gauzes above the narrower widths. A set of pieces cut out of a loom is called a *length*, and a set of half pieces a *half-length*. The putting in of a fresh set of warps is a tedious operation, which requires from two or three to fourteen days, and proportionably lessens the earnings of the weaver. In the Jacquard loom two weeks out of six are lost in this preparation of the work, besides the delay which he frequently experiences in getting the fresh silk from the manufacturer. A simple change of pattern is often effected with very little loss of time. Wherever it is practicable, the ends of the new warp are fastened to those of the old before it is taken out of the loom, whereby the labour of passing them separately through the eyes or mails of the lisses is saved: this is called *twisting-in*. To *mount* a Jacquard loom, or prepare it for weaving, requires perhaps a month or more, but a change of pattern is often affected with very little loss of time.

Ribbons are made according to a fixed standard of widths, designated by different numbers of pence, which once no doubt denoted the price of the article, but at present have reference only to its breadth. The French distinguish their widths by simple numbers.

All dressed ribbons, as satins, gauzes, &c., are made in the loom one-twelfth of an inch wider than sarsenets, in order to allow for the diminution of breadth which results from the lengthwise stretching which they receive in the operation of dressing. Fine gauzes require an allowance of two-twelfths.

Standard width in inches.	$\frac{1}{4}$	$\frac{7}{16}$	$\frac{5}{8}$		$\frac{10}{12}$	$1\frac{1}{12}$		1	$1\frac{7}{12}$	$1\frac{10}{12}$	$2\frac{1}{12}$		$2\frac{7}{12}$	$3\frac{1}{12}$			$3\frac{10}{12}$		$4\frac{7}{12}$

The French ribbons were made formerly in pieces of 12 ells; their length is now the same as that of the English. French fancy ribbons are generally made and sold in *garnitures*, that is, a broad and narrow piece taken together of the same pattern.

Sarsenet and lutestring ribbons are made by the simple and regular alteration of the warp and shoot, as in plain cloth, called technically *ground*. Lutestrings are sarsenets above the width of 12*d*., and in general of stouter make. Several threads of the warp pass through each *dent* or *tooth* of the sleigh, according to the fineness of the silk or intended quality of the ribbon. In a lutestring the dents are in the proportion of about 40 to the inch—the shoots about 90, varying with the quality. By *grogram* (French *gros-grains*) is meant a variation in the texture, caused by the warp-threads passing over two of the shoots at once, taking up one only: this often finishes the edge of a ribbon.

Organzine dyed *soft* is used for the warps of all ribbons except gauzes, from its greater strength and compactness of fibre; tram and singles dyed *souple* for the shoot of sarsenets and sometimes of satin.

In *satin* the glossy appearance is given by the threads of the warp being laid chiefly on the surface, each thread of the warp being crossed by the shoot only once in five times, as in 5-lisse satin, or once in eight times, as in 8-lisse or the superior satins. French satins were formerly made from 6-lisse to 10-lisse. Satins are woven with the face downwards, as it is easier to raise the harness connected with $\frac{1}{5}$ or $\frac{1}{8}$ of the warp each time that the shuttle passes than to raise $\frac{4}{5}$ or $\frac{7}{8}$. The number of dents and shoots to the inch are nearly the same for satin as for lutestring. The threads between each dent are generally put in in odd numbers, 9, 11, 13, which are supposed to fall in better, and produce a better surface. The French satins are lighter in make than the English, but they have a peculiar richness and lustre, owing to their superior silk. French ribbons in general have less weight of silk than the English.

The transparency of *gauze* is produced by the kind of silk of which it is made—the fine hard-twisted marabout, which leaves the interstices clear. One warp thread only passes between each dent of the sleigh, and these are closer together in general than lutestrings and satins. In fine gauzes 80 or more dents, and from 90 to 120 shoots to the inch. The plain gauze ribbons made at Coventry called China gauzes are chiefly those used for mourning—white, black, and lavender, with satin or ground stripes.

Floret Gauzes and Taffeties are light ribbons made of organzine warp shot with hard or marabout silk. There is considerably less labour in these than in other gauzes; they are largely manufactured at Bedworth.

Loves are inferior gauzes made of organzine, and singles dyed *hard*, or upon the gum.

Petershams or *Pads* (derived perhaps from the French *padou*, a coarse ribbon used by tailors, made of linen and silk, often stiffened by gum), are stout thick ribbons used for the waist.

The sleighs employed for making plain ribbons (*taffetas*) in France, have about 51 dents to the inch, for satin 54, for gauze 72-78-84, for velvet 36-42.

These ribbons all belong to the plain trade. The fancy trade comprises the manufacture of the same fabrics figured, under the heads of figured sarsenets, satins, gauzes, and pads.

The figures are frequently produced in a different colour from the ground by the mixture of colours in the warp; the colours being warped separately. In the intervals of the figures the coloured threads are carried along the under side of the ribbon; it is said to have a double or treble figure, according to the number of colours passing through each dent. In some ribbons, gauzes in particular, these threads are cut away by the scissors after the ribbon is made. This is called clipping. A change of colour in the shoot is effected by the use of different shuttles; in brocades the figure is made by small additional shuttles, thrown in partially across the ribbon as the pattern may require; the connecting threads of shoot being clipped off. By damask is meant the laying of the warp over the shoot to form the figure in the manner of satin. The patterns are sometimes geometrical, but more frequently combinations of leaves, sprigs, or flowers. In the superior French ribbons groups and wreaths of flowers are executed with the richness and variety of hand-embroidery. The French are continually introducing novelties in colouring and in texture. In one of recent appearance the ribbon is laid over with a slight covering like crape, by means of a warp of hard-silk woven in loosely over the other: in another the ribbon is made by stamping to assume the appearance of lace.

Some fancy ribbons are of plain texture but varied in colouring; they are shot or woven in shades, stripes, bars, or cheques, called in the trade plaids; these last, which require the shuttle to be changed very frequently, are still made in the single-hand loom. In shot ribbons the warp and the shoot are of different colours. A pearl-edge is frequently given to all kinds of ribbon except the narrower widths of sarsenet. This is formed by the shoot passing over horse-hairs placed outside the warp parallel with it, and raised in like manner by the lisses; as the hairs are drawn out, the silk is left in loops at the edge. Many varieties of ornamental edges, as scollops, fringes, &c., are produced by *drawing in*. The shoot in this case stops short of the edge of the ribbon, catching in an additional thread of silk, sometimes of a different colour, which it draws in in its place, and which is delivered from a bobbin at the back of the loom, and is in a manner darned into the ground of the ribbon.

Clouding is a peculiar management in the dyeing, by which a change of hue is produced in the same thread of silk. The silk, already warped, is tied up and wound closely round with packthread at regular intervals of more or less than an inch, so that the intermediate spaces only are penetrated by the dye.

In one species of fancy ribbon, called *Chiné*, the figures are printed or painted on the warp after it is prepared for the loom, and afterwards woven in by the shuttle; others are embossed after the mode of the Parisian Chandelier.

Ribbons are watered by passing two pieces together between two cylinders, one of which has a heater within it. The irregular pressure of the inequalities of the two surfaces of silk against each other produces a wavy appearance.

Satins are soft and flossy when taken out of the loom; to smooth and stiffen them, they are calendered, or pressed between heated steel cylinders, and afterwards dressed, or passed over a small cylinder covered with flannel, which is moistened with a size made from buffalo hides, and then over a large one of heated steel. Gauzes also are dressed, and sometimes even lutestrings. The French goods are in general better dressed than the English.

The *blocking* of the finished ribbons, or the winding them on cylindrical pieces of wood, is generally done at the warehouse of the manufacturer.

Galloons and *doubles* are strong thick ribbons, principally black, used for bindings, shoe-strings, &c. The narrow widths are called galloons; the broader, doubles. Italian silk is used in making the best qualities only, Bengal for the commoner. They are manufactured at Spitalfields, at Reading, in Devonshire, in the power-looms of Manchester, at Derby, and other places. There is a considerable expor tation of these goods, as there is likewise of the produce of the steam ribbon-looms.

Ferrets are coarse narrow ribbons shot with cotton, used for similar purposes.

Ribbon velvets are manufactured in Spitalfields and at St. Etienne: they are also made at Crefeld in Rhenish Prussia, which has long been a principal seat of the velvet manufacture. The following were the prices paid in 1832, by a principal firm of that place, for the weaving of ribbon velvets:—

			s.	d.	
No. 12	8 pieces in one loom		1	1	for 36 yards.
24	6	"	1	7½	"
30	6	"	1	9½	"
50	5	"	2	3	"
100	3	"	4	3	"
150	3	"	6	9	"

One man makes thirty-six yards in two weeks on an average. The ribbon-weavers live in the country, and those who make the narrow numbers are miserably poor, though they make 288 yards in a fortnight. Italian silk only is used. (*Commons' Committee*, 1832.)

In *gold* and *silver* ribbons a silk thread of similar colour is wound round by a flattened wire of the metal, and afterwards woven. Lyon was particularly celebrated for its fabrics of this kind.

The following table and lists are extracted from the valuable Report of J. Fletcher, Esq., on the Hand-loom Weavers, from which very considerable assistance has been derived in the details of the Coventry trade.

Approximate Statement of Coventry Weavers' Earnings when in full work, at different periods.

Artisans earning the Wages below stated.	1795	1805	1813	1818	1823	1831	1838	Observations.
	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.	
Undertakers in the single-hand trade, supposing each to have on the average 7 looms, and to receive from each one-half a journeyman's wages . .	about 15 9	about 15 9	35 0	19 3	19 3	19 3	18 6	The proportion of deduction for fire and light, to which the earnings of the journey-hands have been subjected, multiplied, allows for the current shop expenses of the undertaker; and his apprentice looms compensate for any deficiency of profit out of looms worked by women.
Journeymen weavers in the single-hand trade	probably 4 6	probably 4 6	10 0	5 6	5 6	5 6	5 0	These earnings are the groundwork of the preceding statement.
Half-pay apprentices in the single-hand trade	about 3 0	about 3 0	about 7 6	about 4 0	about [illegible] 0	about 4 0	about 3 9	Half of the warehouse prices paid to these learners is one-fourth less than the journey-hand pay, which is two thirds.
'First-hand journeymen' in the plain engine-loom, owning their looms, as they now commonly do, after deducting every expense, but without making any deduction for loom-hire since the commencement of the journey-work system	..	..	..	..	..	11 10	11 6	These earnings doubled, for the 2 looms which are on the average worked by each family, ought properly, in estimating the journeyman's condition, to supersede those placed next below them, since they would then contain the profit which the journeyman of late years derives from being proprietor of his own looms, with the addition of rent paid him for other looms; and therefore show his present income, as compared with the prices below, which show his former income.
Journeymen weavers in the plain engine-loom (deducting loom-rent since they have been owners of their looms, as being profit, and not wages) . .	8s. to 12s.	17 0	20 0	10 0	17 0	10 10	10 6	These earnings, and those of the single-hand journeymen, are the proper comparative tests as to the price of mere labour, in contrasting one period with another, and looking at prices generally.
'Journeymen's journeymen' in the plain engine-loom, in the same position under the 'first-hand' journeymen that the latter formerly held under an undertaker, and consequently the first that are thrown out of work at a slack time	..	..	..	..	..	9 10	9 6	These are the earnings of a class approaching in position the journey-hands under the undertakers in the single hand trade, and, like them, among the first thrown out of work at a slack time.
'First-hand journeymen' in the Jacquard engine-loom, owning their looms, as in the plain engine-trade . .	..	..	..	..	..	16 6	15 6	These earnings properly take the place of those formerly obtained in the plain engine-loom, in a comparison of earnings at successive periods; the plain engine-loom being formerly as much the sole superior class of work over the single-hand loom, as this is now over the plain engine-loom.
Journeymen weavers in the Jacquard engine-loom (deducting a loom-rent, which they have to pay when not proprietors of their looms) . . .	..	..	..	..	..	15 0	14 0	These figures are inserted to compare with previous mere wages in the plain engine-loom, which are hence seen to have declined from their money-rate in the steady times of trade of 1805 and 1823, although the money income of the workman differs much less.
'Journeymen's journeymen' in the Jacquard looms, if at two thirds pay .	..	..	..	..	..	..	about 10 6	These are the hands first thrown out of work at a slack time.
Factory journeymen in the Jacquard engine-loom, in the highest paying factories	..	..	..	..	..	.	13 0	The difficulty of obtaining approximate estimates of these, and of all earnings in the figure-branch, is exceedingly great.
Factory journeymen in the Jacquard engine-loom in the Bedworth and in the Coventry lower-paying factories .	..	..	..	..	..	..	9s. to 12s.	
Factory journeymen in the Jacquard engine-loom in the Nuneaton factories.	..	..	..	..	..	..	8s. to 9s	
Half-pay apprentices in the engine trade	..	..	..	..	..	..	say 5s. 6d	These are chiefly in the figure-trade.
Winders (women and children)	..	..	..	..	..	..	3s. to 11s.	Averaging 7s. or 6s. 6d.
Warpers (chiefly women and children)	..	..	..	..	..	..	8s. to 18s.	Averaging 10s.

								..	20	3	6	..	20	3	6

* The late and continued (1840) depression of trade has caused great departure from this list; a considerable reduction has been made in the price of weaving sarsenets; on satins it amounts to 20 per cent. It is feared at Coventry that the increasing preference for French satins will extinguish this branch of the trade.

Shading 6*d.* per gross extra. 5-lisse satins are now seldom made in Coventry. The list of prices refers to the width of the ribbons, not to the quality. The labour is nearly the same for the richer as for the inferior goods, the difference consisting principally in the silk of which they are made. Cheap ribbons are generally made by reducing the warp silk, which is the most expensive, and making up the bulk of the ribbon with a larger proportion of the cheaper shoot. When extra labour is required, it is paid for extra. The average cost of the labour of all the processes of weaving is about 25 per cent. of the price of the goods; in gauzes and figured articles the proportion is higher.

List Price of Power-Engine-Loom-Weaving of plain Sarsenet Ribbons at Derby, 1838.

30	8	24	0	1

It is the universal custom to pay for weaving by the piece; in one instance only, that of the steam-factory, the men receive weekly wages. The *truck* system is unknown, all payments being made in money. It appears that the money amount of the earnings of the ribbon-weavers is not less than it was nearly fifty years ago. The purchasing power of their wages is however greater, and there has been an increase in their domestic comforts, although not in the same ratio as in those of other classes, for in common with the rest of the hand-loom weavers their condition is depressed below that of other artisans. They are less given than formerly to out-of-door amusements and robust exercises, and they have degenerated in physical constitution. Marriages are made much earlier; anxiety of mind produced by family cares in the midst of a fluctuating employment, confinement to the loom, and, among the lower and reckless, the enjoyments of the public-house and gin-shop, induce a great susceptibility to lingering and nervous disorders: they are less liable to acute diseases. Insanity is frequent among them. This inferiority of physical strength presents an obstacle to a change of occupation in bad times, no less than the long exclusive apprenticeship of seven years, the evil of which is peculiarly manifest in this uncertain trade. A want of domestic economy and management results from the employment of women in the trade from their earliest years, but the city weavers, generally speaking, are moral, industrious, attached to their homes and families, and many of them highly intelligent. The condition of the rural weaving population is far worse, and is one of great depression, rudeness, and ignorance.

The number of persons employed in ribbon-making in Coventry, including winders and warpers, was estimated, in 1838, at 6000 or 7000; and in the rural parishes, at 10,000 or 11,000.

RIBBLE, River. [LANCASHIRE.]

RIBCHESTER. [LANCASHIRE.]

RIBE. [JUTLAND.]

RIBEAUVILLE. [RHIN, HAUT.]

RIBE'RA, JOSE', an eminent Spanish painter, better known by the surname of 'Spagnoletto' (the little Spaniard), which the Italians gave him, was born on the 8th of January, 1588, at San Felipe de Xativa, a large town in Spain, about ten miles from Valencia. Having from his early youth shown a great inclination for painting, his parents, though in indigent circumstances, did everything in their power to promote his taste for that art. He was placed as a student under Francisco Ribalta, one of the best painters of the Valencian school, under whom he studied a few years; but before he was sixteen he left his master, and determined to visit Italy. After spending some time at Rome, where he almost lived upon charity, he arrived at Naples in 1606. Here he met with Michael Angelo Caravaggio, whose striking and vigorous style made such an impression upon him, that he never rested until he became his pupil. Under this great master, Ribera made such progress, and his productions were so much admired, that he was considered an accomplished master at the age of twenty. From Naples Ribera went to Parma, where the works of Correggio were then the object of public admiration, and afterwards he visited Rome. Whilst there he attempted to improve his style by imitating the works of Raffaello, but without much success. This circumstance, as well as the great number of excellent artists practising in that city, induced him to return to Naples, where his prospects of employment were greater, that country being then under the dominion of his countrymen the Spaniards. [NAPLES.] After a few months' residence in that capital, the count of Monterrey, the Spanish viceroy, took him under his protection, and employed him in executing considerable works for the king of Spain. In 1630 he was elected a member of the Academy of St. Luke at Rome, and made a knight of the order of Christ by the pope in 1644. Ribera died at Naples in 1656, in the seventieth year of his age. Like his master, his style was characterised by broad lights and shades. His genius naturally inclined him to gloomy or horrible subjects, which he selected both from sacred and profane history. He delighted in designing old men emaciated by mortification, such as hermits and saints, and seems to have at all times rejoiced in the picturesque display of bone, veins, and tendons. In tragic compositions, martyrdoms, executions, and torments, he was eminently successful, and he treated these appalling subjects with a correctness of design and a fidelity which might serve as a study for the anatomist. Thus the spasms of Ixion, St. Bartholomew under the butcher's knife, the torments of Sisyphus, Tantalus, and Prometheus, Laocoon and his sons attacked by serpents, were his favourite subjects. His principal pictures are in the Royal Museum at Madrid, in the Escurial, and at Naples, in which last place he painted the Martyrdom of S. Januarius, for the royal chapel; St. Jerome and S. Bruno, for the church of the Trinity; and the Taking Down from the Cross, for the Carthusians. Ribera sometimes indulged himself in engraving, and he also made six-and-twenty etchings, which were executed in a bold and free style, and with great correctness of design.

(Cean Bermudez, *Diccionario Historico de los Pintores Españoles*, Mad., 1800, vol. iv., p. 184.)

RIBES (a name formerly given to a species of rheum), is a genus of plants forming the natural order Grossulaceæ. As this genus is the only one in the order, its characters, geographical range, and affinities are described with the order. It is well-known as producing the currant and gooseberry, and also for affording many of the ornamental shrubs of our gardens.

De Candolle divides the genus Ribes into four sections, of which the following is an analysis:—

Shrubs with prickles:—
  Peduncles 1-2-3-flowered. GROSSULARIA.
  Peduncles many flowered. BOTRYCARPUM.
Shrubs without prickles:—
  Calyx campanulate . . RIBESIA.
  Calyx tubular . . . . SYMPHOCALYX.

* GROSSULARIA.

This section includes some handsome shrubs, as well as the species which produces the common gooseberry. Of these we shall notice a few that are most commonly found cultivated in this country.

R. Oxycanthoides, Hawthorn-leaved Gooseberry. Prickles infra-axillary, solitary. Leaves glabrous, lobes dentate. Peduncles short, bearing 1-2 greenish white flowers. It is a native of rocky districts in Canada, and bears a fruit very much resembling that of the common gooseberry both in appearance and taste. Like many other described species of large genera, it has been supposed to be referrible to a more common form, the *R. grossularia*.

R. niveum, Snowy-flowered Gooseberry. Prickles solitary, in pairs or threes. Leaves glabrous, roundish, entire at the base. Flowers two together in peduncles, Sepals reflexed. Stamens longer than the style. It grows to the height of 4 or 5 feet. It was found on the north-west coast of America by Mr. Douglas, who sent the seeds to England

* Sometimes less.

in 1826. The fruit is about the size of the black currant, of a deep red-purple colour. It is said to be of a superior flavour to the common gooseberry. 'It has a rich subacid rather perfumed flavour, which is extremely agreeable. The fruit is rather too acid to be eaten raw; but when ripe it makes delicious tarts, and would probably afford an excellent means of improving the common gooseberry by hybridising.' (Lindley, *Bot. Reg.*, Aug., 1834.) The white flowers give it a handsome appearance when it blossoms, making it a valuable addition to our ornamental shrubs.

R. Cynosbati, Dog-bramble Gooseberry. Infra-axillary prickles 1-2. Leaves 3-4, lobed, pubescent. Calyx campanulate, cylindrical. Petals shorter than stigma and stamens. Berry prickly. This plant is found in Canada, according to Pursh, and was discovered in India by Royle, and in Japan by Thunberg. It differs little from another well-known species, *R. divaricatum*, which has the tube of the corolla somewhat narrower and the stamens longer. Two varieties of this plant are recorded: one with smooth fruit, a native of Hudson's Bay; the other with prickly branches and fruit, shorter peduncles, pubescent purplish flowers, from Lake Huron.

R. grossularia, Common Gooseberry. This plant is too well known to require any description here, and is probably the parent of many of the other recorded species of Ribes. It is found wild in almost every part of England and Scotland, growing on old walls, in hedges and woods, although a question might be raised as to its being aboriginal in this island. It seems to be truly indigenous in France, Germany, and Switzerland; and, according to Dr. Royle, is found in the Himalaya and on the banks of the Ganges. It has also been seen growing in North America, on rocks near the Falls of Niagara.

This plant does not appear to have been known to the antients; and the earliest author who mentions it is Matthiolus, an Italian botanist. It was recorded as existing in England by Turner, Parkinson, and Gerard; but Ray is the earliest writer who mentions it as a cultivated species. The Dutch were the first to cultivate the gooseberry successfully, but even up to the time of Miller it seems to have gained very little repute in England as a fruit for the table. From its extensive cultivation, it has received a great variety of names. In Cheshire and the north of England it is called *Feaberry*, in Norfolk *Feabes*, both of which names are corruptions of Fever-berry, as, according to Gerard, it was at one time considered a specific against fevers. *Grozzer* is a common name for it in Scotland, which seems to be derived from the French name *Groseille à Macquereau*, which is again derived from the Latin Grossularia, and the use of the fruit as a sauce with mackerel. Its common name, *gooseberry*, is derived from gorse-berry, because its prickles resembled those of the furze or gorse. Some derive this name from its berries being used as sauce for geese. [GOOSEBERRY.]

There are numerous varieties of this plant recorded, which chiefly vary in the extent, size, and number of their prickles, and in the shape and size of their fruit and flowers.

R. speciosum, Showy Gooseberry. Shrub prickly, infra-axillary prickles 3. Branches hurspid. Leaves glabrous, on short petioles, 3-lobed. Peduncles with 1-3 deep red flowers, longer than leaves. Stamens 4. Filaments and style red. This plant was found by Mr. Menzies on the western coast of California. Since its introduction into this country it has been a great deal cultivated on account of its beautiful crimson flowers. In its cultivation it requires some care, as the branches are so much reclined, that unless carried up against rock-work or a wall, the flowers will not be well seen. *R. Menziesii* seems to be only a variety of this species.

** BOTRYCARPUM.

This section includes four species intermediate between gooseberries and currants: they are however called by the former name. *R. orientale*, Eastern Gooseberry, with yellow green flowers, blowing in April and May. It is a native of Syria. *R. saxatile*, Rock Gooseberry, a native of Siberia, with greenish-purple flowers.

R. diacantha, Twin-prickled Gooseberry. It flowers in May and June, having yellowish flowers and cuneated leaves. It grows wild in Dauria and other parts of Siberia. *R. lacustris*, Lake-gooseberry, a native of moist places in Canada and Virginia, with flowers like a currant and leaves like a gooseberry.

*** RIBESIA.

This section includes the greater number of the currants, of which there are about forty species. The most common and useful of these is the *R. rubrum*, Common red currant. The name currant seems to be derived from the similarity of the fruit to the Corinth raisin, or small grape of Zante, which are commonly called Corinth's, or currants. This last is too well known to need a description. It is a native of Europe and Siberia, and the northern parts of North America, to the mouth of the M'Kenzie, and is found in mountainous districts in the north of England and Scotland. Like most plants that are easily disseminated and occupy varied elevation, latitude and soil, this species is subject to many varieties. Of these seven have been recorded by De Candolle, which vary in the shape, size, and covering of their leaves, as well as the size and colour of their fruit. The writer of the article 'Ribes' in Loudon's *Arboretum et Fruticetum Britannicum*, observes, 'the common red currant is commonly treated by botanists as a distinct species, but we have no doubt whatever that *R. petræum*, *R. spicatum*, *R. alpinum*, *R. prostratum*, and several other botanical species are essentially one and the same thing. We have arrived at this conclusion from the study of the plants in the very excellent collections of this genus which are in the garden of the Horticultural Society of London and in the arboretum of the Messrs. Loddiges.'

The currant is not mentioned by Greek and Roman writers, but it is scarcely possible that its beautiful red and sweet berries should have been neglected by the people amongst whom they grew. In France they were cultivated long before the gooseberry, but were first produced in perfection by the Dutch. Gerard mentions that they were cultivated in gardens in his time. Till a recent period very few varieties were known, but several have been lately introduced, especially by the exertions of the late Andrew Knight, Esq. The following is a list of the principal varieties from Don's Miller's 'Dictionary:'—

Red Currants.

1. *Common red, groseiller rouge à petit fruit, groseiller ordinaire à fruit rouge.*
2. *Red Dutch, large red Dutch, new red Dutch, large red, large branched red, Morgan's red, red grape, groseiller rouge à gros fruit.*
3. *Knight's large red.*
4. *Knight's sweet red currant.*
5. *Knight's early red currant.*
6. *Champagne, groseiller à fruit couleur de chair.*
7. *Striped leaved currrant and variegated-leaved currant.*
8. *Large pale-red Dutch.*

White Currants.

1. *Common white currant, groseiller à fruit blanc.*
2. *White Dutch currant, new white Dutch, Morgan's white, white crystal, white Leghorn, peurl white.*
3. *Pearl white, blanc perle.*
4. *Spearey's white.*

Of these varieties those numbered 2 and 8 among the red, and that 2 of the white, are the best.

The fruit of the various species of Ribes has been used in medicine to allay thirst, and it is said to lessen the secretion of bile. The juice of the red currant is sometimes employed in making punch, and mixed with water forms the *eau de groseilles* of the French. It is also made into jelly, and the berries are used for making tarts and puddings. When ripe the fruit makes an excellent wine, which is much used in the rural districts of England.

Cultivation.—All the sorts are hardy plants, growing freely and bearing a plentiful crop of fruit. They thrive almost as well in one situation as another, whether it be open or shady, free or confined. This permits of the ripening of the fruit throughout a long period, so that it may be obtained as early as June and as late as October. Common garden soil is suited to them, which should be tilled and recruited from time to time with fresh manure. The largest crops are produced in a strong loam or improved clay-soil. They are earlier in a light soil. Previous to planting, the soil should be dug two feet deep, and this may be done at any time from October to February or March. They are chiefly propagated by cuttings obtained early in the spring. These should consist of the previous year's shoots taken from bearing-branches and be from ten inches to a foot in length. They should be planted 4 or 5 inches deep and may be watered in spring. In the summer all the shoots or buds should be removed except three. In the following autumn they may be transplanted. Currant bushes are best planted by themselves, and the distance between the rows should not be less than from 7 to 9 feet. They will grow freely against a wall, and when thus planted with a south or south-west aspect will produce ripe fruit three weeks earlier than standards with a north or north-east aspect: fruit may be preserved good till October, and if matted, as late as November. Grown on espalier rails the fruit is produced in the finest order.

The fruit of the currant should be gathered in dry weather, as when gathered in rain it loses its flavour.

R. nigrum, Black Currant. Flowers whitish or yellowish green. Calyx a rich brownish red or pink colour. The stamens and petals frequently present a remarkable peculiarity: the usual number of each is five; but should either the petals or stamens be increased in number, the other is diminished; thus if there are seven stamens, there will be but three petals, and if there are ten stamens, there will be no petals, and *vice versâ*. The peculiar strong smell of the leaves of this plant is very characteristic. The black currant has the same geographical range as the red, but is found more abundantly in the north than in the south of Europe. It is now common in Great Britain, but is probably not indigenous. It is found in Siberia, on the Caucasus, and in Sweden. It is indigenous in the woods of Russia as far as St. Petersburg, and in this district the fruit is found green, yellow, or even white. Species of Ribes are also found in India and South America with black fruit. There are three wild varieties: *R. bacca flavida*, with a dingy greenish-yellow fruit, supposed to be a hybrid between black and white currant; *R. bacca virida*, with green fruit; *R. foliis variegatis*, with leaves streaked with yellow. The principal garden varieties are

1. *Wild black.*
2. *Black grape, Ogden's black grape.*
3. *Black Naples, Cassis* of the French.
4. *Green-fruited black.*
5. *Russia green.*

Of these, that numbered 3 is decidedly the best for use.

The fruit of the black currant is not in so great repute as the red, and is of comparatively modern introduction. Gerard mentions it, and says that its berries are of a stinking and somewhat loathsome flavour. It is often used as a medicine. The leaves and fruit are diuretic, and are employed in the composition of the Siberian *quass*. An intoxicating spirit is distilled from the berries, and they are also used for colouring various kinds of spirits in Siberia. As a popular remedy for sore throat, they are much employed for making jelly, especially in Russia and Scotland. The leaves are frequently used by the poor to mix with black tea in order to give it the flavour of green.

R. sanguineum, Bloody or Red-flowered Currant. Leaves cordate, serrated, villous beneath. Racemes drooping, twice the length of leaves. Calyx with spreading segments. This is the most ornamental species of the genus, bearing large racemes of deep rose-coloured flowers, which are followed by berries of a bluish-black. It is a native of the north-west coast of America. This as well as the other species of currants may be propagated in the manner described for the red currant. As this plant has been extensively cultivated, a great many varieties are to be found.

R. atropurpureum, Dark Purple-flowered Currant. Stem erect. Leaves pubescent. Racemes drooping. Calyx ciliated. Berries dark purple, glabrous. It is a beautiful shrub, a native of the Altai and mountainous districts on the river Ural, but it has not yet been introduced into this country.

**** Symphocalyx.

The species of this section are cultivated entirely as ornamental shrubs.

R. aureum, Golden-flowered Currant. Petiole glabrous. Leaves 3-lobed, shorter than the petioles. Calyces longer than pedicels. Petals linear, shorter than calyx. Flowers golden-yellow. Fruit yellow, and of an agreeable flavour. It is a native of the north-west of America. Of this plant there are varieties, *R. præcox*, *R. villosum*, and *R. serotinum*. They are all beautiful shrubs, and deserve a place in every collection. Of the remaining species, *R. tenuiflorum* and *R. flavum* are well worthy of cultivation.

RIBGRASS. [Plantaginaceæ.]

RICARDO, DAVID, to whom the science of political economy is perhaps more indebted than to any other man of our own day, was born in London on the 19th April, 1772. His father, a native of Holland, had then been for several years a member of the Stock Exchange in London; and designing his third son, David, for the same occupation, gave him a good but plain commercial education. For this purpose he was sent, when eleven years of age, to a school in Holland, where he remained for about two years. Soon after his return to England he was taken into his father's office as a clerk, and, when of age, was associated with him in business. In 1793 he formed a matrimonial alliance displeasing to his father, by reason of his religious scruples, the elder Mr. Ricardo having been born of Jewish parents, and continuing to profess their faith until his death. This breach between the father and son, which was afterwards entirely healed, necessarily caused their separation as regarded business, and threw the subject of this notice altogether upon his own efforts, seconded however, in a manner highly honourable to all parties, by many of the leading members of the Stock Exchange. Mr. Ricardo continued to be a member of the Stock Exchange until 1818, and was eminently successful, taking for many years a leading part in its business, and realising a princely fortune by conduct which gained for him universal respect.

During the years in which Mr. Ricardo was most actively engaged in business, he continued to devote much time to study and to scientific pursuits. He was one of the original promoters of the Geological Society of London, and for some years a member of its council: he also acquired a considerable knowledge of chemistry, as well as an acquaintance with mathematics. Of late years, the powers of his mind were almost wholly devoted to the elucidation of questions connected with political economy, a study which was at once best suited to the peculiar quality of his mind and most in unison with his daily pursuits in business, and by his attainments in which he was enabled to take his place among the deepest and most original thinkers of his day.

In the beginning of 1819, Mr. Ricardo was returned to parliament by the Irish borough of Portarlington, which place he continued to represent until his death.

The reputation which Mr. Ricardo had previously acquired by his writings ensured to him the attention of the House on all occasions when he spoke, and not unfrequently induced the members present to call upon him for his opinion when the subject-matter of the debate was such as might receive light from his extensive knowledge. Although he confined himself in his parliamentary speeches almost entirely to subjects of finance, and such as fell strictly within the line of economical science, his reported speeches are numerous; and although, from the nature of the subjects which he handled, and with which the newspaper reporters could not be familiarly acquainted, it could hardly be expected that justice could be done to his reasonings, these reports yet furnish a full justification of the desire so constantly evinced by the House, and ample reason for the respectful attention which he always experienced. During each of the five sessions in which he sat in parliament, his name constantly appears as a speaker; and in the latest two years of the series (1822 and 1823) his addresses were very frequent. Although his voice was not good, and his utterance was rapid, it was yet so distinct, that he could be heard without an effort by every member present. His manner was wholly unpretending, and his argumentative style was unrelieved by any oratorical effort; he endeavoured to convince by reason, and to influence only by truth and justice. Those persons who had most narrowly watched the progress of his public career, felt justified in predicting for him a future of the highest usefulness; and had his life been spared, it is reasonable to think that their predictions would have been fulfilled. At the close of the session of 1823, he retired to his estate of Gatcomb Park in Gloucestershire, and, after a very few days' illness, died on the 11th September, of an inflammation of the brain, in the fifty-second year of his age. In private life, Mr. Ricardo was extremely amiable; his temper was mild and equable, and he enjoyed in the highest degree the respect and affection of every member of his family.

Mr. Ricardo first appeared as an author during the discussions that led to and accompanied the famous Bullion Committee in 1810. His pamphlet, which was entitled 'The High Price of Bullion a Proof of the Depreciation of Bank Notes,' speedily passed through four editions, and occasioned the publication of several replies. His next publication was entitled 'A Reply to Mr. Bosanquet's Practical Observations on the Report of the Bullion Committee;' and however much opinions may at that time have been divided upon the subject, it has long since been generally acknowledged that the victory rested with Mr. Ricardo. Although the peculiar interest which attended those discussions has long since passed away, Mr. Ricardo's pamphlet will be read with pleasure by all who delight in marking the ease with which a man of superior intellect can trace and exhibit the constant and active operation of general principles through all the intricacies of practical detail.

In 1815 Mr. Ricardo published 'An Essay on the Influence of a Low Price of Corn on the Profits of Stock,' in which he combated the justice of restrictions on the importation of corn; but the essay is chiefly remarkable for the doctrine which it propounds concerning rent. [RENT.] The following year produced 'Proposals for an Economical and Secure Currency, with Observations on the Profits of the Bank of England.' The principal recommendation put forth in this pamphlet was, that the Bank of England should be obliged to exchange its notes for gold ingots of a certain fineness, and not below a certain weight, at prices diminishing from time to time, until the price should be brought down from its then market rate to the Mint price of 77*s.* 10½*d.* per oz.

Mr. Ricardo's great work, that upon which his lasting fame as an economist must rest, 'On the Principles of Political Economy and Taxation,' was published in 1817, and was at once pronounced the most valuable contribution made to economical science since the days of Adam Smith.

In 1822 Mr. Ricardo again appeared as the author of a tract entitled 'On Protection to Agriculture,' in which he exposed certain fallacies and prejudices of the landed proprietors. The effects of legislative protection afforded to products of the soil upon wages, profits, public revenues, and non-agricultural branches of the national industry, are all discussed within the limits of eighty-seven pages, with a clearness and precision that may be said to exhaust the matter, and which prove the author to have been perfect master of the whole subject.

The only remaining work of Mr. Ricardo was found among his papers after his death, having been the latest matter of a public character that occupied his attention. This was his pamphlet in recommendation of a national bank, which was soon afterwards published by his family, in the exact state in which he left it probably only a few days before his death.

RICAUT, SIR PAUL. [RYCAUT.]

RICCI or RIZZI, SEBASTIA'NO, a painter, born at Cividal di Belluno, near Trevisano, in the Venetian state, in 1659 or 1660. He was placed early under the tuition of Frederigo Cervelli, at Venice. He accompanied his preceptor to Milan, and afterwards went to Bologna and Venice, to study the master-pieces of those two schools. He resided for some years at Florence and Rome, and ultimately made a tour of the whole of Italy, executing pictures at any price, wherever he obtained commissions, and leaving behind him a reputation almost universal. He afterwards travelled into Germany, England, and Flanders, completing his style from a careful study of the works of other artists, and especially improving in his mode of colouring. At Vienna he executed many works for the court, particularly some paintings on the walls of the imperial palace of Schönbrunn, and thence he returned to Florence, where he was employed to decorate several of the apartments in the palace of the grand-duke. Being invited to England by Queen Anne, he travelled through France, and at Paris was made a member of the Academy of Painting. The picture he executed for Chelsea Hospital, in the cupola of which he represented the Ascension, and the staircase of Montague House, now the British Museum, which he also decorated, prove him, says M. Périès, in the 'Biographie Universelle,' to be capable of great undertakings. He also painted the chapel at Bulstrode, for the duke of Portland, in the altar-piece of which, representing the Last Supper, he has introduced his own portrait in a modern habit. The hall and some of the ceilings of Burlington House, London, are also by him.

During his residence in England, which lasted ten years, he was most extensively employed, and his departure is said by Walpole to have been caused by disgust that Sir James Thornhill should have been selected to paint the dome of St. Paul's Cathedral. On quitting this country he returned to Venice, where he was constantly occupied on pictures for France, Spain, Portugal, and Sardinia. Ricci, in common with Luca Giordano, possessed the power of imitating with great exactness the style of the great masters who preceded him. Some of his pictures appear at first sight as if painted by Bassano or Paul Veronese, and one of his Madonnas, exhibited at Dresden, was for some time attributed to Correggio. This facility of imitation is said, by the writer of the Life of Mignard, in 'L'Histoire des Premiers Peintres du Roi,' p. 152, to have deceived La Fosse as to the genuineness of one of his pictures in the style of Paul Veronese, a deception which called forth the sarcastic advice that Sebastian 'should thenceforth paint nothing but Paul Veroneses and no more Riccis.'

In his historical compositions Sebastiano is rather an imitator than a plagiarist, as in the Last Supper, in the church of Santa Giustina, at Padua, which greatly resembles the cupola of S. Giovanni at Parma, by Coregg , and his S. Gregorio, at S. Alessandro in Bergamo, re to mind the work of Guercino at Bologna. The same may be observed of his scripture histories, painted for S. Co and S. Damiano, at Venice, which are preferred to any others that he executed for that place.

Sebastiano Ricci did not early acquire an extensive knowledge of design, but he cultivated it in after-life with extreme assiduity in several academies. The forms of his figures are composed with beauty, dignity, and grace, li those of Paul Veronese: his attitudes are natural and var , and his composition is managed with truth and judgme . His colouring is distinguished by a beautiful azure, wh remains in his fresco works, but in his pictures in oil, fr the badness of the grounds, that as well as the other t has faded.

Opinions vary much concerning the merit of this painter. M. Périès, following Lanzi, speaks of him in the man above quoted, and Lanzi is in some respects far more e gistic. Mr. Bryan observes, that though his design is n scrupulously correct, the forms of his figures are grace , and his colouring, though sometimes feeble and cold, often silvery and agreeable; and that, like most painters of decorations, he consulted his imagination more than natu , and frequently discovers the repetition and the weakness of a mannerist. A careful examination of the works he executed in this country will lead us to the conclusion at wh an able writer in Rees's 'Cyclopædia' has arrived, that was one of the few, comparatively speaking, who enjoy du their lives the utmost extent of their fame. In fact he w a machinist, one who, being conversant with the rules of art and skilful in the application of the means, dazzl where he could not instruct, and deluded by ingenuity wi out judgment and art without expression. In many his works he was assisted by his nephew Marco Ricci, w resided with him in England.

Sebastiano died at Venice, on the 5th of May, 1 Amongst the most noted of his productions may be enu rated the Massacre of the Innocents, at Venice; the R of the Sabines, at Rome; at Bergamo, Saint Gregory s plicating the Virgin in favour of the Souls in Purgat before referred to; at Vienna, several ceilings of the i perial palace, and an Assumption of the Virgin, at t church of St. Charles.

(Lanzi, *Stor. Pitt.*, iii. 225; *Biographie Univers* ; Walpole's *Anec. of Painting*, by Dallaway, iii. 281-2; Bry *Dict. of Painters*.)

RICCI. [JESUITS; PIUS VI.]

RICCIARELLI, DANIELE, generally called Dan di Volterra, from the place of his nativity, was born 1509. He appears to have first studied at Siena, un Antonio Razzi, called Il Sodoma, and afterwards Baldassare Peruzzi. In the expectation of receiving gre encouragement at Rome, he repaired to that city, when was first employed as an assistant to Pierino del Vaga the Vatican, and in the Capella Massimi, in the church the Trinità del Monte. He was chiefly indebted for reputation which he subsequently acquired to the frien and instruction of Michael Angelo, who gave him design the works which he executed in the Farnesina, and for oth of his most celebrated performances. The principal m ment of his fame was the series of frescoes in the churc La Trinità del Monte, representing the History of the Cr on which he was employed seven years. Of these fresc the most remarkable was the famous Descent from the Cr which was universally esteemed as one of the three fi pictures at Rome; the other two being the Transfigur by Raphael, and the Communion of St. Jerome, by Dom chino. It has been affirmed that Michael Angelo not assisted him by his advice, superintendance, and corrections, in the composition of this sublime performance, but that the figure of the Saviour and that of the Virgin Mary must have been the work of his master-hand. Unhappily we are unable to judge of the probability of this assertion; for the French, in their rapacious eagerness to possess so fine a work, barbarously attempted to detach the plaster from the wall, and broke it all to pieces. We have no means of judging of the grandeur of the composition but from the fine engraving of it by Dorigny. On the death of Pierino del Vaga, in 1547, he was recommended by Michael Angelo to Pope Paul III. as superintendant of the works in the Vatican, of which, and of his pension, he was deprived by Julius III.

Pope Paul IV., conceiving that the nudity of several figures in the Last Judgment was unsuitable to the sanctity of the place, had determined to destroy that great work; when Daniel undertook, and, according to a tradition which appears to be authentic, with Michael Angelo's own consent, to clothe the offensive figures. He was probably induced to do this, in order to save the picture from destruction, for which however he was ever afterwards called in ridicule Braghettone. He died at Rome, 1566, at the age of 57.

RICCIOLI, GIOVANNI BATTISTA, was born at Ferrara in 1598, and became one of the principal cultivators of astronomy in Italy during the greater part of the seventeenth century. He entered into the Society of the Jesuits in 1614, and having diligently cultivated all the different branches of learning as they were taught in that age, he was chosen teacher of philosophy, rhetoric, poetry, and theology, in the colleges of their order at Parma and Bologna; but his inclination leading him to the study of geography and astronomy, he gave up his appointments, and applied himself wholly to the prosecution of those sciences.

His first published work was the 'Almagestum novum' (1653), which constitutes a treatise on astronomy. In it he mentions the origin of the science, and gives a list of those who had cultivated it: he also describes his method of measuring a degree of the earth's surface, and a pendulum of his own invention. He computes the obliquity of the ecliptic, the length of the tropical year, and the elements of the orbits of the sun, moon, and planets; he also treats of eclipses, and gives a long list of such as had been observed from the earliest time. The work contains a treatise on parallaxes, and some ideas of the writer concerning the body of the moon.

The learned world was then divided between the followers of Aristotle and the disciples of Copernicus in their opinions respecting the system of the universe. In the 'Almagestum,' Riccioli, having explained the ideas of the last-mentioned philosopher concerning the movement of the earth, offers a long series of objections to them, which, with a brief reply to each, may be seen in Delambre (*Histoire de l'Astron. Mod.*, tom. i., p. 679, &c.). He acknowledges however that the more we examine the hypothesis of the earth's several motions, the more we must admire the genius and sagacity of Copernicus, who had been able to explain so simply the phenomena of the heavens; and he expresses his regret that the fruits of a brilliant imagination should be set forth as realities. The admiration constantly expressed for Copernicus, and even the manner in which the objections to his theory are stated, have led to a belief that this learned Jesuit was a Copernican in his heart; and, from a passage in the work, it appears that the Aristotelians and theologians of that day, in their opposition, were more afraid of the consequences of making concessions in favour of a theory which seemed to them to be at variance with the letter of the Scriptures, than inimical to the theory itself.

The 'Almagestum' contains many passages which betray the prejudices of the age. As a reason for the necessity of reforming the calendar, Riccioli asserts that the blood of St. Januarius continued to liquefy on the 19th of September, though the time of the equinoxes had been anticipated by ten days: he finds several causes for the supposed eclipse of the sun which took place at the death of Christ, and he dwells at some length upon those which, it has been imagined, will immediately precede the end of the world.

In 1661 Riccioli published a work on geography and hydrography, in which is given an account of the operations which, in conjunction with P. Grimaldi, he had carried on in order to determine the length of a degree of the terrestrial meridian. For this purpose a base-line was measured near Bologna, and a triangulation was formed between that city and Modena; the stations appear however to have been improperly chosen, for the angles between them are often less than eight degrees, and only two were observed in each triangle. The instrument employed for obtaining the terrestrial angles was similar to the parallactic rulers of Ptolemy; and, in reducing the distances between the stations to one spherical surface, Riccioli assumed the refraction as constant, and equal to thirty minutes, as it had been determined by Tycho Brahé for celestial bodies in the horizon. The latitudes of the stations were determined by the sun and certain stars, their altitudes being observed with a quadrant whose radius was eight feet; but the declinations were taken from the catalogue of the astronomer just mentioned, and consequently were liable to errors amounting to one minute or more. It appears also that Riccioli entertained an opinion that the measures of the ancients were nearly correct; hence, among his observations, he made choice of such as gave results which approached the nearest to those measures, and thus his determination of the length of a degree is found to have been very erroneous. The value expressed by 64,363 paces of Bologna (= 66,773 Eng. fath.), which he obtained by one of his methods, is considered by him as possessing an evidence in its favour which nothing can resist; it however differs far more from the truth than the determination of Snell, which had been made a few years previously in France; and in fact it is too great by above 6000 fathoms. The same work contains some remarks on the variation of the magnetic needle, observations on geographical longitudes and latitudes, and several problems relating to navigation.

Lastly, in 1665, Riccioli published his 'Astronomia Reformata,' a work in which he treats of refractions and parallaxes, and describes the instruments which he used to determine the places of the stars. He also gives a collection of the observations previously made on the planets, and he compares them with the astronomical tables which had then been published. The work concludes with several tables relating to chronology, geography, and astronomy, and with a catalogue of stars.

This writer, who is considered as having been less useful to mankind by his discoveries than by the care which he took to record those of his predecessors, died in 1671, at the age of seventy-three years.

RICE. In the article ORYZA [vol. xvii., p. 46] an account has been given of the botanical character and mode of cultivation of this useful grain. In order to remove the husk, which adheres very closely, without breaking the grain itself, several ingenious machines have been recently introduced, of some of which it is proposed to give a brief notice, referring for more detailed information to Hebert's 'Engineer's and Mechanic's Encyclopædia,' article 'Rice.'

The common mode of performing this operation in India and China, is by beating the grain in a kind of rude mortar of stone or earthenware, with a conical stone attached to a lever worked by the hand or foot. Sometimes several such levers are moved by arms projecting from the axis of a water-wheel. This process being uncertain and tedious, the preference has been given of late to a kind of mill, in which the stones are placed at such a distance asunder as to detach the shell without crushing the grain; the stones being enclosed in a case which prevents the dispersion of the rice by the rapid rotation of the machine. The rice is thrown out of the case by an opening in its side, and conducted over a sieve that separates the dust; after which it is made to fall in a gentle stream exposed to a current of air, produced by revolving fanners, and thereby separated from the husk. Such a sifting and winnowing apparatus is attached to each pair of stones, and, according to the work above referred to, one pair of stones will husk from eight to ten bushels an hour. After the removal of the husk, the grain is exposed to the action of a whitening machine, which removes the inner cuticle, or red skin, remaining on the surface of the grain. The machine used for this purpose very nearly resembles that described in vol. iii., p. 467, for the preparation of barley. This process is aided by the heat generated by the rapid motion of the grains, causing them to swell and split the red skin, which flies off in dust through perforations in the revolving case. With such accuracy are these processes performed, that it is said not more than five per cent. of the grain is broken in the operation.

The method of cleansing rice just described has been practised in Ceylon with British machinery; but other plans have been followed successfully in this country, where, owing to the difference between the duties on cleaned rice and *paddy*, or grain in the rough state, and the better preservation of the flavour of the rice when brought over in the husk, several large rice-cleaning establishments have been recently brought into operation. The process of Messrs. Lucas and Ewbank, for which patents were obtained in 1819 and 1827, consists in breaking the husk by mill-stones, and removing the red cuticle by beating or triturating in mortars; the latter operation being aided by mixing a quantity of the husks, well dried, with the grain, which obviates an inconvenience occasioned by the glutinous character of the red coating. The refuse matter and the broken grains are then separated by a peculiar kind of screen, and the rice is finally cleaned and polished by a machine with two concentric cylinders, the outer one remaining stationary, while the inner one, which is covered with sheepskin with the wool on, is caused to revolve with great velocity. The rice, being placed between the two cylinders, is thoroughly whitened by the friction of the wool.

In the apparatus patented by Mr. Shiel, the first operation is performed between one millstone and a piece of wood of precisely similar shape, and the subsequent removal of the dark pellicle is effected by rubbing between flat wooden surfaces covered with sheepskin, but with this distinction, that while Mr. Ewbank places the wool outwards, Mr. Shiel has it next the wood; its elasticity producing an effect very nearly resembling the rubbing of the grain between the palms of the hands.

Another ingenious contrivance, first used in the United States, consists of a long hollow cylinder of wood, with several bars projecting from its inner surface, and enclosing an axis on which are several other bars capable of revolving between those attached to the cylinder. By suitable toothed wheels the cylinder is made to revolve slowly in one direction, while the axis is turned with great rapidity in the contrary direction. The whole being placed in an inclined position, the paddy is allowed to enter the upper end of the cylinder by a hopper, and the mutual attrition of the grains, as they pass between the revolving bars, causes the separation of the husks, which are removed by a current of air as the grain falls into a bin under the lower extremity of the cylinder. The rice passes out of the cylinder by apertures capable of being enlarged or reduced at pleasure by means of sliding doors; and the action of the machine may be further regulated by varying the inclination of the cylinder, which may be placed vertically or horizontally, though an angle of about 45° is preferred.

Allusion has been made to the difference of the duty on cleaned rice and paddy, which, as may be seen from the following statement from Ellis's 'British Tariff,' 1839, discourages the importation of cleaned rice from foreign countries. The scale of duties is—

Rice, not being rough and in the husk .	15*s*. per cwt.
Rice in the husk, or paddy .	2*s*. 6*d*. per bushel.
Paddy imported from the West Coast of Africa . .	1*d*. per quarter.

If the produce of any British possessions, the duties are—

Rice, not being rough and in the husk .	1*s*. per cwt.
Rice in the husk, or paddy . .	1*d*. per quarter.

A drawback is allowed on the exportation of foreign rice that has been cleaned in this country; such drawback amounting to 10*s*. per cwt., which is equal to the duty paid on four bushels of paddy at 2*s*. 6*d*. per bushel.

RICE GLUE. [CEMENT, vol. vi., p. 412.

RICE PAPER, the name commonly, but erroneously, applied to a delicate vegetable film brought from China in small square pieces, tinged with various colours, and used as a substitute for drawing paper in the representation of richly coloured insects or flowers, and also in the manufacture of artificial flowers and other fancy articles.

This substance, which is said to be a membrane of the bread-fruit tree (*artocarpus incisa*), is minutely described in a paper by Dr. Brewster, in the second volume of the 'Edinburgh Journal of Science,' from which it appears that though much resembling an artificial production, its vegetable organization is easily seen by the aid of a microscope, which shows 'that the rice-paper consists of long hexagonal cells, whose length is parallel to the surface of the film; that these cells are *filled with air* when the film is in its usual state; and that from this circumstance it derives that peculiar softness which renders it so well adapted for the purposes to which it is applied.'

RICE BIRD, one of the names of the *Paddy Bird*, *Puddee Bird*, or *Java Sparrow* (*Loxia oryzivora* of Linnæus).

This well-known bird, whose plumage is well described by Buffon as being so well arranged that no one feather passes another, whilst all appear to be covered with that kind of bloom which is visible on plums, giving them a beautiful tint, has the bill very much developed; indeed, with the exception of *Pyrenestes* and, perhaps, *Coccothraustes*, this finch is the most remarkable of the race for the size and power of that organ.

Description.—Bloomy lead-coloured, head and tail black, bill red, belly obscurely rosy, cheeks in the male snowy, legs flesh-coloured.

Locality, Habits, &c.—In Java, where it is called *Glatik*, and the other parts of Asia where it is found, it has a very bad reputation on account of the ravages which it commits in the rice-fields with its powerful and sharp bill. In Sumatra the name of the bird is *Boorong Peepee*. It is often brought alive to this country, and confined in aviaries for the sake of its elegant shape and graceful colouring: its song, which is short and monotonous, does not much recommend it. This species must not be confounded with the *Rice Bird* of America, *Emberiza oryzivora*, Linn. [BOB-O-LINK.]

Loxia oryzivora, Linn. Fringilla oryzivora of Swainson and authors. Upper figure, female; lower figure, male. (Swainson.)

RICH, CLAUDIUS JAMES, was born on the 28th March, 1787, near Dijon in Burgundy, and, while yet an infant, was carried to Bristol, where he spent the early years of his life. He received a good education, and was early distinguished by his extraordinary powers in the acquisition of languages. At the age of eight or nine he happened to see some Arabic manuscripts in the library of a gentleman at Bristol, and was seized with a strong desire to acquire that language. This accidental circumstance led him to study the Oriental languages, in which he made such proficiency as to be able to read with considerable facility the Arabic, Hebrew, Syriac, Persian, and Turkish languages by the time he had attained his fifteenth year. His extraordinary acquirements in Oriental literature a duced a friend to obtain for him, in 1803, the appointment to a cadetcy in the East India Company's service; and he was shortly after presented with a writership in the Bombay establishment by Mr. Parry, the chairman of the board of directors, in consequence of the strong recommendation of Sir Charles Wilkins. To enable him to perfect himself in the Arabic and Turkish languages, he was attached as secretary to Mr. Lock, who was at that time proceeding to Egypt as consul-general; and after the death of Mr. Lock, which happened before Mr. Rich joined him, he was allowed by the court of directors to prosecute such a course of travel as it was supposed might be most conducive to the object which he had in view. He accordingly went to Constantinople and Smyrna to study the Turkish language, and thence proceeded to Egypt to perfect himself in the Arabic and its various dialects. After leaving Egypt, he travelled over a great part of Palestine and Syria in the disguise of a Mameluke, and, confiding in his knowledge of the Turkish language and manners, ventured to visit the grand mosque at Damascus, while the great body of pilgrims was assembled at that city on their way to Mecca. From Syria he proceeded by Mardin and Bagdad to Bussora, whence he sailed for Bombay, which he reached in September, 1807.

On his arrival at Bombay, he resided at the house of Sir J. Mackintosh, to whom he had been introduced by the Rev. Robert Hall previous to his departure from England. In the following year he married the eldest daughter of Sir J. Mackintosh, and was shortly afterwards appointed the East India Company's resident at Bagdad, where he remained for about six years. During this time he prosecuted with the greatest diligence his favourite studies. He formed a rich collection of Oriental manuscripts, and also of medals and coins, and of the gems and engraved stones found at Babylon, Nineveh, Ctesiphon, and Bagdad. He made an excursion to Babylon in 1811 for the purpose of examining the ruins of that city, and afterwards published at Vienna, in the 'Mines de l'Orient,' a 'Memoir on the Ruins of Babylon,' which was subsequently reprinted in this country. In consequence of a paper published by Major Rennell, in the 'Archæologia,' containing 'Remarks on the Topography of Ancient Babylon, suggested by the recent Observations and Discoveries of C. J. Rich, Esq.,' in which he questioned some of his conclusions, Mr. Rich undertook another journey to Babylon, and in 1818 published, in London, a 'Second Memoir on Babylon,' in which he endeavoured to confirm the correctness of his first account; to this memoir he also added a valuable appendix on Babylonian antiques, illustrated by engravings, which represent fac similes of many cuneiform inscriptions found upon bricks at Babylon. A second edition of these Memoirs, with the narrative of Mr. Rich's journey to Babylon in 1811, and to Persepolis in 1821, was published by his widow in 1839.

In 1813 Mr. Rich, being compelled by bad health to leave Bagdad for a time, travelled to Constantinople, and subsequently to Paris. He returned to Bagdad in 1815, where he resumed his former pursuits, and made large additions to his collection of MSS. and antiques. During this time he made the second excursion to Babylon already referred to: and in 1820 he made a tour into Koordistan. He went as far east as Sinna, and visited Sulimania, Mosul, and the ruins of Nineveh, and returned from Mosul to Bagdad down the Tigris. The journal which he kept on this occasion was published in 1836 by his widow, under the title of 'Narrative of a Residence in Koordistan,' and was accompanied by a valuable map of the country between Sinna, Arbil, and Mosul, which was drawn up from Mr. Rich's survey and astronomical observations. On his return to Bagdad, he intended to proceed to Bombay, where he had been appointed to an important office by the Hon. Mountstuart Elphinstone, who was then governor; but in consequence of an attack made upon the residency by the orders or with the connivance of the pasha, he retired to Bussora. While waiting for instructions from his own government, he employed his time in a tour to Shirauz, whence he visited the ruins of Persepolis and other remains of antiquity in that neighbourhood. While at Shirauz, he was attacked by the cholera morbus, and died of that disease on the 5th of October, 1821.

Mr. Rich's death was a great loss to his private friends and to Oriental literature. His disposition was amiable and kind, and his knowledge of many Oriental languages such as few Europeans have ever possessed. The Memoirs on Babylon were the only writings which he published in his lifetime, with the exception of a few articles in the 'Mines de l'Orient;' but he left behind him a considerable number of papers on various subjects. His collection of Oriental MSS., of coins and antiquities, was purchased by parliament for the British Museum. Mr. Rich, during his second residence at Bagdad and on his various excursions, was unwearied in his astronomical observations. He has left a very complete series of eclipses of Jupiter's satellites, and numerous altitudes of stars and lunar distances, most of which are computed, and the results in latitude and longitude deduced. It is probable that a re-calculation of the observations, *correcting the errors of the Ephemerides by contemporary observations at the standard observatories*, would improve the geography of the countries through which he travelled, though with a considerable amount of computation. Unfortunately his chronometer was so indifferent that the partial results cannot be combined. The emersions of Jupiter's first satellite observed at Bagdad, when so computed, throw the longitude a little to the east of Beauchamp's and Murphy's determinations. This seems to show that, from the clearness of the atmosphere or superior quickness of eye, Mr. Rich anticipated other observers, and saw the re-appearances earlier. His zeal as an observer may be estimated from the fact that when taking the sun at Bagdad the metal of his sextant was frequently too hot to be touched without pain; and after the most fatiguing marches, and while labouring under severe indisposition, he seized every favourable opportunity of fixing his position astronomically.

(*Brief Notice of the Life of Mr. Rich* prefixed to Mr. Rich's 'Narrative of a Residence in Koordistan.')

RICHARD I. II. OF NORMANDY. [NORMANDIE.]

RICHARD I., King of England, surnamed *Cœur de Lion*, was the third son of Henry II. and his queen Eleanor, and was born at Oxford, in the king's manor-house there, afterwards the monastery of the White Friars, in September, 1157. The history of the earlier part of the life of Richard has been already detailed. [HENRY II.] By the treaty of Montmirail, concluded 6th January, 1169, between Henry and Louis VII. of France, it was stipulated that the duchy of Aquitaine should be made over to Richard, who should do homage and fealty for it to Louis, and should espouse Adelais, or Alice, that king's youngest daughter; and in 1170, Henry, being taken ill at Domfront, in Maine, made a will, by which he confirmed this arrangement. In 1173, Richard, with his younger brother, Geoffrey, and their mother, joined their eldest brother, Henry, in his first rebellion against their father; on the submission of the rebels, in September, 1174, Richard received two castles in Poitou, with half the revenue of that earldom, and, along with Geoffrey, did homage and swore fealty to their father; nevertheless Richard continued from this time to hold the government of the whole of Aquitaine, and to be usually styled, as before, duke of Aquitaine, or duke of Poitou (which were considered as the same title), although it appears that Henry now looked upon the arrangements made at the treaty of Montmirail as annulled, and that dukedom to have actually reverted to himself. (Lyttleton's *Hist. of Henry II.*, vol. iii., p. 371.) In 1183 Richard refused, when commanded by his father, to do homage for Aquitaine to his elder brother Henry, on which Henry and Geoffrey invaded the duchy, and a new war ensued between them and their father assisted by Richard, which however was terminated by the death of the eldest of the three brothers, in June of that same year, when Richard became his father's heir apparent; but at an interview between King Henry and Philip Augustus of France, in November, 1188, Richard, apparently impelled by a suspicion that his father intended to leave his crown to his younger brother John, and also professing to resent Henry's conduct in withholding from him his affianced bride, the French king's sister, suddenly declared himself the liegeman of Philip for all his father's dominions in France; whence arose a new war, in which Philip and Richard speedily compelled Henry to yield to all their demands, and a treaty to that effect was about to be signed when Henry died, on the 6th of July, 1189. Richard was present at the burial of his father in the choir of the convent of Fontevraud.

Notwithstanding his apprehensions, real or affected, of his brother John, Richard made no particular haste to come over to England; but, contenting himself with ordering his mother Queen Eleanor to be liberated from confinement, and to be invested with the regency of that kingdom, he first proceeded to Rouen, where he was formally acknowledged as duke of Normandy, on the 20th of July, and it was the 15th of August before he arrived at Portsmouth (or, as others say, at Southampton). His coronation, from which the commencement of his reign is dated, took place in Westminster Abbey, on the 3rd of September. It was on occasion of that ceremony that a furious riot broke out against the Jews in London, which was in the course of the next six months renewed in most of the great towns throughout the kingdom. At York, in March, 1190, a body of five hundred Jews, with their wives and children, having taken refuge in the castle, found no other way of saving themselves from their assailants, except by first cutting the throats of the women and children and then stabbing one another.

A short time before his father's death, Richard and his then friend Philip Augustus, had, as it was expressed, taken the cross, that is to say, had publicly vowed to proceed to the Holy Land, to assist in recovering from the infidels the city and kingdom of Jerusalem, which had recently (A.D. 1187) fallen into the hands of the great Saladin. The mighty expedition in which all the principal nations of Western Christendom now joined for the accomplishment of this object is known by the name of the Third Crusade. Leaving the government of the kingdom during his absence in the hands of William Longchamp, bishop of Ely and chancellor, and Hugh Pudsey, bishop of Durham and justiciary, Richard took his departure from England on the 11th of December of this same year, 1189, and, proceeding to Normandy, united his forces with those of Philip Augustus in the plain of Vezelai, on the 1st of July, 1190. The two friends proceeded together at the head of an army of more than a hundred thousand men as far as Lyon, where they separated on the 31st; Philip taking the road to Genoa, Richard that to Marseille, where he was to meet his fleet. The fleet however not arriving so soon as was expected, Richard in his impatience hired thirty small vessels for the conveyance of himself and his suite, and, sailing for Naples, arrived there on the 28th of August. On the 8th of September he proceeded by sea to Salerno, where he remained till the 23rd, and then sailed for Messina, which port his fleet had reached about a week before, with the army, which it had taken on board at Marseille. The French king had also arrived at Messina a few days before his brother of England.

The two kings remained together at Messina till the end of March, 1191. During their stay Richard compelled Tancred, who had usurped the crown of Sicily, to relinquish the dower of his sister Joan, the widow of William, the late sovereign, and to pay him besides 40,000 ounces of gold. In return he betrothed his nephew Arthur, the son of his next brother, Geoffrey, to Tancred's infant daughter, and formed a league offensive and defensive with the Sicilian king—a connection which afterwards cost him dear, for it was the source of the enmity of the emperor Henry VI., who had married Constantia, the aunt of William, and claimed the throne of Sicily in right of his wife, who was undoubtedly the legitimate heiress of her deceased nephew. After the dispute with Tancred had been settled, the latent rivalry of Richard and Philip broke out in a quarrel about the Princess Adelais, whom her brother Philip insisted that Richard should espouse, in conformity with their betrothment, now that his father no longer lived to oppose their union. But if Richard had ever cared anything (which there is no reason to suppose he did) for the French princess, that attachment had now been obliterated by another which he had some years ago formed for Berengaria, the beautiful daughter of Sancho VI. (styled the Wise), king of Navarre; in fact, he had by this time sent his mother Eleanor to her father's court to solicit that lady in marriage, and, his proposals having been accepted, the two were now actually on their way to join him. In these circumstances, Philip found himself obliged to recede from his demand; and the matter was arranged by an agreement that Richard should pay a sum of ten thousand marks in five yearly instalments, and restore Adelais, with the places of strength that had been given along with her as her marriage portion, when he should have returned from Palestine. Adelais was in fact sent home some years after, and eventually she became the wife of William, earl of Ponthieu, by whom she had a daughter who was married to Ferdinand III., king of Castile, and was the mother of Eleanor, wife of our Edward I.

Richard, having sent his mother home to England, sailed from Messina on the 7th of April, at the head of a fleet of above two hundred ships, of which fifty-three were large vessels of the sort styled galleys; his sister the queen dowager of Sicily and the Princess Berengaria accompanying him. The king of France had set sail about a week before. Several months however elapsed before Richard reached the Holy Land, having been detained by an attack which he made upon the island of Cyprus, Isaac the king or emperor of which had ill used the crews of some of the English ships that had been driven upon his coasts in a storm. Richard took Limasol, the capital, by assault; and that blow was soon followed by the complete submission of Isaac and the surrender of the whole island. Isaac was put into confinement, and remained a captive till his death in 1195. Meanwhile the island of Cyprus was made over by Richard in 1192 to Guy of Lusignan, upon his resignation of the now merely titular royalty of Jerusalem to his rival Henry of Champagne; and Guy's posterity reigned in that island till the year 1458.

Having married Berengaria at Limasol, Richard set sail from Cyprus on the 4th of June (1191), with a fleet now described as consisting of thirteen large ships called busses, fifty galleys, and a hundred transports; and on the 10th he reached the camp of the Crusaders assembled before the fortress of Acre, the siege of which had already occupied them not much less than two years, and had cost the lives, it is said, of nearly two hundred thousand of the assailants. But the presence of the English king, although he was suffering from severe illness, and had to be carried to the trenches in a litter, immediately inspired so much new vigour into the operations of the Christian army, that on the 12th of July the place surrendered, and Saladin, who had been harassing the besiegers from the neighbouring mountains, withdrew in conformity with the terms of capitulation. This great event however was immediately followed by an open rupture between Richard and king Philip, whose rivalry had already exhibited itself in a variety of ways, and more particularly in the support given by the former to the claim of Guy of Lusignan, and by the latter to that of Conrad of Montferrat to the vacant crown of Jerusalem. Philip in fact took his departure from Palestine on the last day of July, leaving only ten thousand men under the command of the duke of Burgundy.

Richard performed prodigies of valour in the Holy Land, but, although a signal defeat of Saladin, on the 7th of September, was followed by the capture of Jaffa and some other places of less importance, Jerusalem, all along professedly the main object of the crusade, so far from being taken, was not even attacked. Jaffa however, after it had again fallen into the hands of Saladin, was recovered by the impetuous valour of the English king. At last, on the 9th of October, 1192, Richard set sail from Acre in a single vessel, his fleet having on board his wife, his sister, and the daughter of the captive king of Cyprus, having put to sea a few days before. The three ladies got safe to Sicily; but the first land the king made was the island of Corfu, which he took about a month to reach. He left Corfu about the middle of November in three coasting-vessels, which he hired there, but, after being a few days at sea, he was compelled by a storm to land on the coast of Istria, at a spot between the towns of Aquileia and Venice. After narrowly escaping first from falling at Goritz into the hands of Maynard, a nephew of Conrad of Montferrat (to whose murder in Palestine Richard, upon very insufficient evidence, was suspected to be an accessory), and then at Freisach from Maynard's brother, Frederic of Betesow, he was taken on the 21st of December at Erperg, near Vienna, by Leopold, duke of Austria (a brother-in-law of Isaac of Cyprus), and was by him consigned to close confinement in the castle of Tyernsteign, under the care of his vassal, baron Haldmar. In the course of a few days however, by an arrangement between Leopold and the emperor Henry VI., the captive king was transferred to the custody of the latter, who shut him up in a castle in the Tyrol, where he was bound with chains and guarded by a band of men who surrounded him day and night with drawn swords. In this state he remained about three months. Meanwhile intelligence of his having fallen into the hands of the emperor had reached England, and excited the strongest sensation among all ranks of the people. A sketch of the course of events there during his absence has been given in the article on John. It is sufficient to mention that a struggle for supremacy had for some time been carrying on with various success between the king's brother John and Longchamp, the chancellor.

who had acquired the entire regency, and had also been appointed Papal legate for England and Scotland; and that this had issued, in October, 1191, in the deposition of Longchamp by a council of the nobility held in St. Paul's churchyard, London; after which he left the country, and although he soon ventured to return, ultimately deemed it most prudent to retire to Normandy. The supreme authority was thus left for a time in the hands of John, who, as soon as he learned the news of his brother's captivity, openly repaired to Paris, and did homage to the French king for the English dominions on the Continent. On his return to England, John raised an army to support his pretensions, and his confederate Philip took up arms in his behalf in France, and, entering Normandy, overran a great part of that duchy, although Rouen, the capital, was preserved principally by the exertions of the earl of Essex, lately one of Richard's companions in the Holy Land. In England also John met with a general opposition to his usurpation of the regal authority, which soon compelled him to conclude an armistice with a council of regency that had been appointed by the prelates and barons. This was the position of affairs when Longchamp, having discovered Richard's place of confinement, after much solicitation prevailed upon the emperor to allow the royal prisoner to be brought before the diet at Haguenau, where accordingly he made his appearance on the 13th of April, 1193, and defended himself with so much eloquence against the several charges made against him in regard to Tancred and the kingdom of Sicily, to his conquest of Cyprus, and to the murder of Conrad of Montferrat, that Henry found himself compelled by the general sentiment of the diet to order his chains to be immediately struck off, and to agree to enter upon negotiations for his ransom. Longchamp was immediately despatched to England with a letter to the council of regency, and the result was, that, notwithstanding the insidious efforts both of John and his friend Philip of France to prevent the conclusion of the treaty, Richard was at last liberated, on the 4th of February, 1194, after 70,000 marks had been actually paid to the emperor, and hostages given for the payment of 30,000 more. The English king had also engaged to release both Isaac of Cyprus and his daughter, and he had besides, at the persuasion, it is said, of his mother Eleanor, the more effectually to conciliate Henry, formally resigned his crown into the hands of the emperor, who immediately restored it to him to be held as a fief of the empire, and burthened with a yearly feudal payment to his superior lord of five thousand pounds. This strange transaction rests on the apparently satisfactory authority of the contemporary annalist Hoveden. Richard, descending the Rhine as far as Cologne, proceeded thence across the country to Antwerp, and, embarking there on board his own fleet, landed at Sandwich on the 13th of March.

Most of John's strongholds had been wrested from his hands before his brother's return, and now the rest immediately surrendered, and he himself fled the country, and with his principal adviser, Hugh, bishop of Coventry, having been charged with high treason, and not appearing to plead after forty days, was outlawed and divested of all his possessions.

Meanwhile it was thought necessary, perhaps on account of the formal resignation of his crown which he had been induced to make to the emperor, that Richard should be crowned again; and that ceremony was accordingly performed at Winchester, by Hubert, archbishop of Canterbury, on the 17th of April. Then, leaving Hubert guardian of England and grand justiciary, on the 2nd of May following, having, with his characteristic activity, employed almost every moment since his arrival in raising an army and procuring funds for its maintenance by all sorts of exactions and the most unscrupulous use of every means in his power, he again set sail from Portsmouth, his whole soul bent on chastising the king of France. Owing to adverse winds, he was a fortnight in reaching Barfleur in Normandy, where, as soon as he landed, he was met by his brother John, who professed contrition and implored his pardon. On the intercession of his mother Eleanor, he consented to receive the submission of the repentant traitor, and to grant him his life, although he refused to restore him his lands. He now marched against Philip, and several engagements took place between them, in most of which the English king was successful. But the war, though it lasted for some years, was distinguished by few remarkable events. A truce for one year was agreed to on the 23rd of July; and, although hostilities were resumed some time before the expiration of that term, a peace was again concluded in the end of the following year, which lasted till the beginning of 1197.

All this time Hubert, assisted by Longchamp, who had been restored to his office of chancellor, is said to have presided over the government at home with great ability. Hubert had been educated under the famous Glanvil, and he seems, in the spirit of his master, to have exerted himself in re-establishing and maintaining the authority of the law, by which alone, even if he did no more, he must have materially contributed to the revival of industry. The large sums however which he was obliged to raise by taxation to meet the expenses of the war, in the exhausted state to which the country had been reduced, provoked much popular dissatisfaction; and the third year of the king's absence in particular was distinguished by the remarkable commotion excited by William Fitz-Osbert, styled Longbeard, a citizen of London, who is admitted to have possessed both eloquence and learning, and whose whole character and proceedings might not improbably, if he had had his own historian, have assumed a very different complexion from what has been given to them. Longbeard, who acquired the names of the Advocate and King of the Poor, is affirmed to have had above fifty thousand of the lower orders associated with him by oaths which bound them to follow whithersoever he led. When an attempt was made to apprehend him by two of the wealthier citizens, he drew his knife and stabbed one of them, named Geoffrey, to the heart, and then took refuge in the church of St. Mary-le-Bow in Cheapside, the tower of which he and his followers fortified, and held for three days, when they were at last, 7th of April, 1196, dislodged by fire being set to the building. Fitz-Osbert was first dragged at a horse's tail to the Tower, and then to the Elms in West Smithfield, where he was hanged, with nine of his followers. The people however long continued to regard him as a martyr. He appears to have been accustomed to appeal to the religious feelings of the populace in his attempts to rouse them against the government; even at that comparatively late day too he raised the old cry of Saxon against Norman, professing to wear his beard unshorn, it is said, out of affection for that custom of the more ancient inhabitants of the land.

The war between Richard and Philip broke out again in 1197, and in the course of this campaign Richard had the gratification of capturing the bishop of Beauvais, a personage whom he had reason to regard as a main instigator of the severities and indignities which he had sustained at the hands of the emperor. The bishop was taken armed cap-à-pie and fighting, and when Pope Celestine recommended him to the clemency of Richard as his son, the English king sent his holiness the bishop's coat of mail, with the following verse of scripture attached to it:—'This have we found: know now whether it be thy son's coat or no.' This same year too finished the career of the emperor Henry, who in his last moments is said to have expressed the extremest remorse for the manner in which he had treated the great champion of the Cross. Richard's other enemy, Leopold, duke of Austria, had been killed by a fall from his horse two years before.

A truce, as usual, at the end of the year, again suspended hostilities for a space. The war was renewed on its termination, and in this campaign (of the year 1198) Richard gained one of his greatest victories, near Gisors, when Philip in his flight fell into the river Epte, and was nearly drowned. After this, by the intervention of the pope's legate, a truce was concluded between the two kings for five years, and they never met again in fight; although they probably would, notwithstanding the truce, if both had lived. But on the 26th of March in the following year, 1199, as Richard was engaged in reducing the castle of Chalus, the stronghold of one of his Aquitanian vassals, Vidomar, viscount of Limoges, who it seems had refused to surrender a treasure found on his estate, to which the king laid claim in right of his feudal superiority, Cœur de Lion was struck in the left shoulder by an arrow, aimed, it is said, at the royal person, from the rampart of the castle, by a youth named Bertrand de Gordon. The wound would not have been dangerous, but for the mismanagement of the surgeon in his attempts to extract the arrow-head, which had broken off in the flesh. As it was, Richard lived only till Tuesday, the 16th of April. The shot was a fatal one in every way; in the fury into which the wound of the king threw the besieging army, the castle was taken by storm, and all the persons found in it were immediately hanged, with the exception only of Gurdun. He was brought into the presence of his dying victim, when Richard, under the impulse of generosity or compunction, gave him his liberty, with a hundred shillings to take him home; but after the king's death he was flayed alive, by order of Marchadee, the leader of the Brabantine mercenaries serving in Richard's army.

Richard I. had no issue by his wife Berengaria, but he is said to have had one or two natural children. He was succeeded on the throne by his youngest brother, John, to the exclusion of Arthur of Bretagne, the legitimate heir, as being the son of his next brother, Geoffrey. [JOHN.]

The character of Richard is one of course not to be judged without reference to the general manners of the age in which he lived. He is charged by writers of his own or near his own time with crimes of all sorts, and it is probable enough that there was hardly an excess, either of violence or licentiousness, into which his impetuous temperament did not occasionally precipitate him; but, besides the sanction or indulgence for all this accorded by public opinion and the universal example, it is also to be said for Richard that, with all his passion and recklessness, he seems to have had nothing base or malignant in his composition; and that he was as capable of acts of extraordinary generosity and disinterestedness as of excesses of brutal fury or profligacy. Of the courage and strength of will proper to his race, he had his full share, with more than his share of their strength of thew and sinew; and his intellectual powers, both natural and acquired, were also of a high order. He was renowned in his own day, not only as beyond all dispute the stoutest and most gallant of living heroes, but as likewise occupying a place in the foremost rank of those who excelled in wit, in eloquence, and in song. Walpole indeed, in his 'Royal and Noble Authors,' tells us that Hoveden, the monkish annalist, 'says positively that Richard, to raise himself a name, bought and begged verses and flattering rhymes, and drew over singers and jesters from France to chant panegyrics on him about the streets, and it was everywhere said that the world contained nothing like him.' But in fact Hoveden says that this was done not by Richard, but by Longchamp, his chancellor. A few of Richard's poetical compositions have been preserved, and may be found in the following works:—'La Tour Ténébreuse,' 1705, which contains a love-song in Norman-French, and another chanson in mixed Romance and Provençal, said to be the joint composition of Richard and his favourite minstrel Blondel de Nesle, and to be that by which Blondel, according to the well-known story, now generally believed to be a fiction, discovered his master's prison; Walpole's 'Royal and Noble Authors,' which contains a poem of about forty lines in Provençal, from a MS. in the Laurentine Library at Florence, another version of which in Norman French (by some supposed to be the original), is given by Sismondi, 'Littérature du Midi de l'Europe,' vol. i., p. 149, and of which there are two English versions, one published in Burney's 'History of Music,' another by the late George Ellis, in Park's edition of Walpole's work; Raynouard's 'Choix des Poésies des Troubadours,' vol. iv., containing the Provençal version of the same poem; and the 'Parnasse Occitanien,' Toulouse, 1819, in which another poem of Richard's is given. Richard is also a distinguished character in romance; on which subject it may be sufficient to refer the reader to Ellis's 'Specimens of Early English Romances,' vol. ii., p. 175-290 (edit. of 1811).

The claim of Richard I. to the authorship of the antient maritime code called the Laws of Oleron, has been shown to be unfounded in another article [vol. xvi., p. 426]. Almost the only improvement in the laws or institutions of England which is attributed to him is some reform of the institution of justices itinerant introduced by his father; but it is not very clear in what this consisted; and, whatever it was, the merit of it appears to belong not to Richard, but to his viceroy Hubert. He is also said to have abolished some of the most cruel penalties of the forest laws, although he enforced that code generally with great exactness. What is called the time of legal memory, or the term requisite to establish immemorial usage, dates from the commencement of the reign of this king; though some recent acts of parliament have altered the law in this respect by shortening the time of prescription. [PRESCRIPTION.]

(The chief contemporary authorities for the history of the reign and exploits of Richard I. are, William of Newbridge or Newburgh, Gervas of Canterbury, Roger de Hoveden, Ralph de Diceto, Benedictus Abbas, Josephus Iscarius, Richard of the Devizes, Greg. Alpharagius, Geoffrey de Vinesauf, and the Arabic historian Bohadin.)

RICHARD II. (surnamed of Bordeaux), King of England, was the second but only surviving son of Edward, styled the Black Prince, eldest son of King Edward III., by his wife Joanna of Kent [EDWARD III.], and was born at Bordeaux on the 3rd of April, 1366. He was consequently ten years and two months old when he lost his father, and not quite eleven years and three months when he succeeded to the throne on the death of his grandfather. His reign is reckoned to have commenced on the day following that event, the 22nd of June, 1377. His coronation did not take place till the 16th of July.

On the accession of a king who was thus still a minor, the powers of government were, by an assembly of the prelates and barons, vested in twelve counsellors, who were appointed to assist, in other words to direct and control, the chancellor and treasurer. From this council the king's three uncles, John of Gaunt, duke of Lancaster, Edmund of Langley, then earl of Cambridge, afterwards duke of York, and Thomas of Woodstock, then earl of Buckingham, afterwards duke of Gloucester, were all excluded; but this arrangement appears to have been collusive, and intended merely to lull the popular dislike and suspicion of Lancaster, in whose interest most of the counsellors are said to have been; and who, although he at first retired to his castle of Kenilworth, was the next year appointed to the command of a fleet fitted out to act against France. In the course of that year, 1378, great honour was obtained by John Philpot, a citizen of London, who, having equipped a small naval armament at his own expense, set sail with it against the Scottish privateer Mercer, who had recently carried off all the ships in the port of Scarborough, and succeeded in capturing him with all his prizes. During the next three years the war with France was prosecuted in Brittany under the conduct of the earl of Buckingham; but the death of Charles V., in September, 1380, having been speedily followed by a peace between the duke of Brittany and the new French regency, Buckingham, now finding an enemy in his former ally, was glad to return home with his army, in April, 1381.

Meanwhile in England the heavy pecuniary exactions called for by the war were hastening on a crisis which other causes had been long contributing to bring about. Three contending forces may be distinctly perceived at work in the ferment which now broke forth. First, there was the crown, or, rather, its natural ally the antient aristocracy, in whose hands the young king on the present occasion was, and of which he may be considered as the mere representative or instrument, striving to protect from encroachment the almost exclusive control of the national affairs which it had possessed at least from the æra of the Conquest. Secondly, there was the recently established House of Commons, the representative of the minor gentry and the middle classes, pressing forward to secure a share in the government, and, with the instinct of a growing power, eagerly seizing hold of every opportunity of forwarding its object, its chief means being the right of taxation, of which it was already in the undisputed enjoyment, and which it had learned to apply with considerable skill as a screw for compressing the crown, and extorting from it new concessions and privileges. It may be remarked that the present state of affairs, with the king a boy and a cipher, and the government in the hands of a regency, was peculiarly favourable for such attempts on the part of the House of Commons. Lastly, there was the great body of the population, forming the labouring class, of which by far the larger portion was yet engaged in agriculture, and in a state of villeinage or servitude, bound to the soil, and so confounded in some sort with the cattle and chattels of the landlord, counted, or at least treated, as *things* not as *persons*, at any rate in so far as all rights of a political character were concerned. But the example of what had recently taken place in other countries, in France and in Flanders, and the progress that the development of society had made among ourselves, had inspired even this the lowest class with a general desire of acquiring a new position in the commonwealth—of being raised from bondage to freedom and citizenship. Of course, both on the part of the House of Commons (or middle classes) and still more on that of the villeins, what was reasonable and right in this ambition may have been mixed with much that was ill-considered, extravagant, and impracticable; their efforts may have been, in some respects, ill-directed, both in regard to ends and means; but in the main, what took place must have happened if society was to advance at all, or even if it was to retain any principle of life. The explosion of these various elements was provoked by the state of pecuniary necessity to which the crown was reduced in the years 1379 and 1380. First, to induce the commons to grant the money that was wanted, it was found necessary, after a short struggle, to submit to their demands, of not only being allowed to inspect the accounts of the royal treasury, but even of appointing the king's ministers. Then, in December, 1380, the famous capitation tax was imposed, which gave rise to the rebellion of Wat Tyler in the summer of the year following. This formidable movement began at Fobbings, near Brentwood in Essex, on the 30th May, 1381, when the people rose against Thomas de Bampton, one of the commissioners who had been appointed to superintend the collection and enforce the payment of the tax. It thence spread over Essex, Kent, Suffolk, Norfolk and other counties along the eastern and southern coasts; the most noted among the popular leaders being two priests called Jack Straw and John Ball; Wat, the Tyler (or tiler) of Dartford, who headed the Kent men, and seems to have been by far the most determined and ferocious of the rebel captains; and two persons of the names of Lister and Westbroom, who were called kings of the commons in Norfolk and Suffolk. In the earlier part of the month of June, Tyler and his followers, having marched upon London, perpetrated a series of frightful devastations: they sacked the archbishop's palace at Lambeth, demolished the Marshalsea and King's Bench prisons, and the duke of Lancaster's palace of the Savoy, set loose the prisoners in Newgate and the Fleet, and destroyed the former building; set fire to the Temple, and to the Priory of the Knights Hospitallers at Clerkenwell; and massacred great numbers of the wealthier classes, among others the two first officers of the kingdom, the archbishop of Canterbury, who was chancellor, and Sir Robert Hales, the treasurer. At last, on the 15th, the career of the demagogue was suddenly terminated by the bold hand of Sir William Walworth, the lord mayor, who, when Tyler, coming forth from his men, rode up to the king stationed in front of the abbey of St. Bartholomew in West Smithfield, plunged a dagger into his throat, on which he was speedily despatched by one or two other persons in the royal suite. Richard himself on this occasion, young as he was, showed great firmness and presence of mind. The insurgents, deprived of their leader, were easily induced to lay down their arms, and in a few weeks the rising of the commons was completely suppressed in all parts of the kingdom. The victory obtained by the king and the government was followed by the shedding of torrents of blood on the scaffold: it is said that the persons executed amounted in all to about 1500; Straw, Ball, and the other leaders being among the number. All the promises also that had been made to the congregated multitudes while they had still arms in their hands, were broken. The Essex men had only asked for the abolition of slavery, the fixing of a maximum for the rent of land, the universal liberty of buying and selling in fairs and markets, and a general pardon; and before they broke up and retired to their homes, they had actually received a written grant of these demands under the king's hand. Even Wat Tyler and the men of Kent, when they came to specify their terms, had insisted upon nothing more extravagant than that the forest-law should be repealed, and all warrens, waters, parks, and woods thrown open, so that the killing of fish, fowl, and game of all kinds should be everywhere free to every man.

On the 14th of January, 1382, Richard was married to Anne of Bohemia, daughter of Charles IV., the late emperor of Germany. The next two years were filled up with a war against the French in Flanders, conducted by Henry Spenser, the young and fighting bishop of Norwich, who in the late commotions had distinguished himself by his decisive style of dealing with the rebels, first, as Froissart tells us, meeting them in the field, and then, when he had routed them, exchanging his sword and armour for a crucifix and sacerdotal robes, and, thus arrayed, confessing and absolving his prisoners as he hurried them to the gibbet; and who now went over to the Continent to assist the burghers of Ghent in their contest with the count of Flanders and the French king, and in support of the cause of Urban VI., in the general European war excited by the struggle between that pope and his rival Clement VII. The bishop in his first campaign defeated the count of Flanders, and took the town of Gravelines, but in the end he was obliged, in the spring of 1384, to make his way back with much precipitation to England, where he was arraigned by the parliament for the failure of the expedition, and his temporalities were seized till the king should be repaid the money it had cost. In 1385 the war with France was transferred to Scotland; and in the summer of that year Richard, for the first time, appeared at the head of his army, which penetrated as far as Aberdeen, having on its way reduced Edinburgh, Dunfermline, Perth, and Dundee to ashes, without having however, during its whole progress, seen the face of the enemy. An expedition of John of Gaunt to Spain, to assert his claims to the throne of Castile and Leon, grounded on his marriage with Constance, the eldest daughter of the late king Peter the Cruel, after occupying him for about three years, terminated, in 1388, in the marriage of the duke's daughter Catherine to Henry prince of Asturias, the heir of the reigning Castilian king John I., an alliance which seated the descendants of the English duke for many generations upon the throne to which he aspired.

Meanwhile, during the absence of the duke, the ascendency at home had been assumed by his younger brother Thomas, now duke of Gloucester; and in the latter part of the year 1387, an ill-conceived and worse-directed attempt of Richard to take the management of affairs into his own hands had resulted in the complete defeat of that design by Gloucester, the execution of Richard's two principal counsellors, the chief-justice Tresilian and Sir Nicholas Brember the lord mayor of London, and the expulsion of the archbishop of York, and of the royal minions De Vere, duke of Ireland, and De la Pole, earl of Suffolk, from the kingdom. The 'wonderful parliament,' as it was called, which met on the 3rd of February, 1388, after ratifying the proceedings of the victorious party, also sent Sir Simon Burley and three other knights to the scaffold, banished four more of the judges to Ireland, and in short completely put down the king's faction. On the 15th of August this year was fought the famous battle of Otterbourne, or Chevy Chase, in which the Scots lost their commander, Earl Douglas, but the English were finally driven from the field, after both their leader Lord Harry Percy (popularly designated Hotspur) and his brother Lord Ralph had fallen into the hands of the enemy.

Richard remained in the state of subjection to which he had been reduced by the 'wonderful parliament' for more than a year. At last, at a great council held in May, 1389, he unexpectedly intimated that, being now in his twenty-second year, he intended to take the management of affairs into his own hands; and the suddenness of the movement secured its success for the moment. Gloucester found it necessary to retire into the country. But, in fact, although no further attempt was made for the present formally to set him aside, his own indolence and indisposition to business very soon threw the government into the hands of his uncle Edmund, duke of York, and Lancaster's son, Henry of Bolingbroke, earl of Derby. John of Gaunt also now returned from the Continent, and had influence enough to force a seeming reconciliation between his royal nephew and Gloucester, and to bring back that duke and his party to court. After this some years passed without any changes or other events of importance. The country was still professedly at war both with France and Scotland; but after the suspension of hostilities had been long kept up by a succession of short armistices, a truce for four years was concluded with both countries in 1394. His queen, who was called 'the good Queen Anne,' having died on Whitsunday in that year, Richard soon after solicited the hand of Isabella, the beautiful but still infant daughter of Charles VI.; after many delays, the treaty of marriage was finally arranged in October, 1396; and at the same time a further peace and alliance was concluded between the two countries for the space of twenty-eight years.

This French marriage is believed to have materially contributed to the domestic revolution that soon after followed. It was opposed before it was contracted, and reprobated afterwards, by Gloucester and the popular party; and on the other hand Richard is supposed to have counted upon the assistance of his father-in-law the French king, to enable him to rid himself of and avenge himself on his uncle. In the beginning of July, 1397, first the Earl of Warwick, and two days after the Earl of Arundel, the most intimate friends and confederates of Gloucester, were suddenly arrested by the orders of the king, who carried his project into effect with profound dissimulation and treachery; and a few days after Gloucester himself was seized in his castle of Plashy, in Essex, and immediately conducted a prisoner to Calais. A parliament was then called, which met on the 17th of September, and which, awed by the display of military force made by the king, and led by the example of the dukes of Lancaster and York and the Earl of Bolingbroke, all of whom Richard had previously seduced or forced into a public approval of the arrests, ratified all that had been done, and impeached the three peers, and also Arundel's brother, the archbishop of Canterbury, of high treason. The archbishop and Warwick were banished for life; Arundel was beheaded on Tower-hill; and when an order was sent to the governor of Calais Castle to bring up his prisoner Gloucester, the answer returned was that he had died, and few doubted that he had been made away with by the king's orders. It was immediately after this affair that Bolingbroke was raised to the dignity of duke of Hereford; Richard's half-brother, Sir John Holland (the son of his mother by her second husband), being at the same time made duke of Exeter. The subservient parliament, before it separated, devolved the whole power of government and legislation upon a commission of twelve peers and six commoners, all devoted to the king; and having also obtained from them the grant of a revenue for life, Richard might now be considered as almost an absolute sovereign.

This state of things however did not last long. Intoxicated by the success of his schemes, Richard now set no bounds to his exactions and extravagance; and, instead of being satisfied with the discomfiture and destruction of so many of the persons whose opposition he had had the most reason to fear, he seems to have been only thereby incited to the devising of means for ridding himself of others whom he still apprehended to be dangerous. Of those who had supported him in the prosecution of the late Duke of Gloucester and his friends, the two most powerful were the Duke of Hereford, and Mowbray, earl of Nottingham, now duke of Norfolk. While Hereford was riding from Windsor to London in December of this same year, he was overtaken by Norfolk, who, according to the account given by Hereford, more than hinted to him that he had reason to suspect the king was watching for an opportunity of destroying them both; his words were carried to Richard, probably by Bolingbroke himself; that nobleman, at any rate, when called upon in parliament to state what had passed, charged Mowbray with having given utterance to the treasonable expressions; and the result was, that after Mowbray had denied the charge, and the two had in compliance with the award of a court of chivalry, presented themselves on the 16th of September, 1398, at Coventry, to decide the matter by wager of battle, Richard suddenly interposed, forbade the combat to proceed, and pronounced sentence of banishment for ten years upon Hereford, and for life upon Norfolk. The issue of the duel, whatever it might have been, would probably have only delivered him from one of his enemies; this method removed both. But one of them doubtless resolved, while professing for the moment to submit to the sentence, that he would not be long in returning. Henry of Bolingbroke had been for some time sedulously and successfully attracting to himself the popular favour which his cousin Richard was fast losing or throwing away: and probably no other subject whom the king might have banished from England could have carried the affections and hopes of so many of his countrymen along with him. This he himself well knew. Accordingly, when in the beginning of February, 1399, about three months after his departure, his father died, and the estates which had now become his inheritance were seized by the crown, he did not hesitate as to the course he should take. Richard had set sail from Milford Haven on the 31st of May, at the head of a fleet of two hundred transports, to quell an outbreak of some of the native tribes of the south of Ireland: Bolingbroke, now calling himself duke of Lancaster, landed at Ravenspur in Yorkshire, on the 4th of July. The returned exile brought with him only forty followers; but by the time he had reached St. Alban's, on his unimpeded march to the capital, his army had increased to sixty thousand men. The Duke of York, in whose charge the government had been left, withdrew towards Bristol, to which place the Earl of Wiltshire, Bussy, Green, and others of the king's friends and servants had previously fled. Bolingbroke merely showed himself to the citizens of London, and, having received their plaudits and addresses of congratulation, set out for the west. York and he met in Berkeley Castle, where the regent after a short conference yielded to all his demands. They marched together to Bristol, where, having taken possession of the castle, Bolingbroke directed Wiltshire, Bussy, and Green to be executed, and then set out for Chester, and established himself in that city. Meanwhile Richard, long detained by tempestuous weather, had at last landed at Milford Haven on the 5th of August. He brought with him the greater part of the army he had carried over to Ireland two months before; but the men nearly all deserted the first night they found themselves again upon English ground. Richard then disguised himself as a Franciscan friar, and, accompanied by the Duke of Exeter and some others of his friends, fled to Conway, where it was understood that the Earl of Salisbury was in command of a numerous royalist force; but upon his arrival he found that that too had broken up some days before. On the 18th the Earl of Northumberland came to him from Bolingbroke, and induced him to accompany him to Flint Castle, where, on the following day, Bolingbroke presented himself at the head of about 80,000 men. The unhappy king proceeded to Chester in the train of his conqueror, and thence in a few days he was carried to London, where he was forthwith lodged in the Tower. Here, on the 29th of September, he consented to read a renunciation of the crown before a deputation of prelates, barons, knights, and lawyers, and to declare that, if he had the right of naming his successor, the man he would fix upon should be his cousin Lancaster. Such at least is the account inserted by Henry's order in the rolls of parliament. On the next day the two houses of parliament met together in Westminster Hall, and voted his deposition, immediately after which the Duke of Lancaster rose and claimed the crown, and was unanimously recognised as king. [HENRY IV.]

Richard did not long survive his dethronement. On the 23rd of October the house of peers, in a new parliament, on being consulted, by king Henry's order, as to what should be done with him, recommended that he should be closely confined in some castle, the knowledge of which should be kept secret from the people; and in conformity with their advice, he was a few days after privately conveyed away from London. All that is further known is, that in the following February rumours were everywhere spread that he was dead, and that in the beginning of March his body, or what was declared to be such, was brought with funeral pomp from Pontefract Castle to London, and there exhibited openly to the people. Afterwards it was reported, by some that he had starved himself to death, by others that he had been starved by his keepers, according to a third version of the story, that he had been violently made away with by Sir Piers Exton, assisted by seven other assassins. For many years also rumours continued to arise from time to time that he had made his escape, and was still alive in Scotland; and an attempt has lately been made to establish the probability of this strange story; but the supposed new evidence brought forward in support of it has been satisfactorily shown to be quite inconclusive.

Of the alterations made in the statute law during the reign of Richard II., the most important was the extension of the former Acts against provisors, or persons obtaining papal presentations to benefices before they were vacant, by a series of new Acts, and especially by the 16 Ric. II. c. 5, commonly called the Statute of Præmunire. [PRÆMUNIRE.]

In 1382 a statute was passed for apprehending and punishing the followers of the religious reformer Wycliffe, who are described as malevolent persons going about from county to county, and from town to town, in peculiar habits, with pretence of great sanctity, and without licence of the pope or the ordinary, preaching daily in the churches, churchyards, markets, fairs, and other open places where the people were assembled in greatest numbers, discourses full of heresies and notorious errors, to the great injury of the faith, and destruction of the laws and estate of holy church, &c. But this Act was repealed the same year, on the representation of the Commons that it had been passed without their assent. Just before its enactment twenty-four opinions, attributed to Wycliffe, had been condemned as heretical and dangerous by a synod of churchmen; the reformer appealed against the decree, but was ultimately induced to submit, and he remained in quiet at his rectory of Lutterworth, till his death, about two years after. His opinions however had already made great progress among the people; and the spirit which he had awakened by his preaching and writings continued to live and spread after his death, and no doubt materially contributed to prepare the way for the overthrow of the old religion, which was effected a hundred and fifty years later.

In the preceding year (1381), after the suppression of Tyler's rebellion, the offence of treason was extended to the act of beginning a riot, rout, or rumour, by the 5 Ric. II., st. 1., c. 7; but this severe enactment was repealed in the reign of Edward VI. This is one of the antient statutes constituting the offence called *Scandalum Magnatum*. To the reign of Richard II. have been assigned the complete establishment of the court of the high admiral, and the enlargement of the jurisdiction of the Court of Chancery by the first issuing of writs of subpœna. [Equity; Pleading in Equity; Subpœna, Writ of.] Finally, the right of impeachment and prosecution by the Commons in parliament, which had been first asserted in the latter years of Edward III., was finally established in this reign by the impeachment of the earl of Suffolk, the late chancellor, in 1386.

Richard II. had no issue by either of his wives (his second indeed was only a child of ten years of age at the time of his death); nor are any natural children assigned to him by the genealogists. Queen Isabel returned to France in 1401, and became the wife of her cousin Charles, duke of Orleans, after bearing a daughter to whom, she died, at the age of twenty, in 1409.

The transactions of this reign must be principally sought from public documents. Of the contemporary historical accounts the principal are, besides the graphic narrative of military transactions by Froissart, a work by a monk of Evesham, published by Hearne, in 1729; Knyghton's 'History of the Deposition of Richard II.,' in Twysden's 'Decem Scriptores;' and an alliterative poem in English on the deposition, and another, in Latin, by Richard Maydiston, a Carmelite friar, entitled 'De Concordia inter Ric. II. et Civitatem London.,' lately published together by the Camden Society. There is also in the Harleian Library (MS. 1319) a very curious history of the close of the reign, embracing both the deposition and the preceding expedition to Ireland, written in French verse by a person who professes to have belonged to the king's suite, and adorned with many illuminations of remarkable beauty and delicacy of execution. This interesting composition has been printed in the twentieth volume of the 'Archæologia,' with a translation and ample annotations by the Rev. J. Webb, and with engravings of all the drawings.

RICHARD III., king of England, was the youngest son of Richard, duke of York, whose descent is given in the article on Edward IV. Richard was born 2nd October, 1452, at Fotheringay Castle in Northamptonshire. On the defeat and death of the duke of York at Wakefield Green, 31st December, 1460, where the duke's second surviving son Edmund, styled earl of Rutland, was also killed, Richard and his elder brother George, afterwards duke of Clarence, were sent by their mother to Utrecht, where they remained under the protection of Philip, duke of Burgundy, till the crown of England was acquired (about two months after) by their eldest brother Edward. Soon after this event Richard was created duke of Gloucester, made a knight of the Garter, and appointed to the office of lord high admiral, though as yet only in his tenth year. In 1469 he was made one of the wardens of the Scottish marches: in 1470 he fled with the king, his brother, to Flanders on the sudden restoration of Henry VI. by the earl of Warwick: in 1471 he commanded the foreward of his brother's army at the battle of Barnet; and he also assisted in gaining for Edward his next and crowning victory of Tewksbury. He and his brother Clarence are asserted to have been the actual murderers of Henry's son Prince Edward, after the battle. [Edward IV.] To Gloucester also was popularly ascribed at the time the murder of Henry himself in the Tower a few weeks after. [Henry VI.] The following year the Lady Anne Nevil, daughter of the earl of Warwick, and widow of Prince Edward, was prevailed upon to give him her hand.

In 1478 Gloucester took a foremost part in the attainder and destruction of his brother Clarence, whose removal placed him next after the king's issue in the order of succession to the throne. In 1482 he commanded an expedition against Scotland, in the course of which he took the town of Berwick and penetrated as far as Edinburgh. He had only recently returned from this expedition, and was still in command of his army on the borders, when the death of his brother took place, in the beginning of April, 1483.

On the receipt of this intelligence, Richard immediately prepared to set out for London, stopping however on his way at York, where he summoned the gentlemen of the county to swear allegiance to Edward V., taking the oath first himself. At Northampton he was met on the 29th of April by the duke of Buckingham, and it is believed that the measures, probably in part arranged previously by letter, were then finally concerted, by which Richard should be elevated to the throne. On the next day Edward's uncle, Earl Rivers, and his half brother, Lord Grey, who were at Stony Stratford with the king, were both arrested by Gloucester's orders; and possession was also taken of the royal person.

From his arrival in London to the disappearance of the young king and his brother towards the end of June [Edward V.], Gloucester, who now called himself Lord Protector, kept his residence at Crosby Place in the City, where he held frequent conferences with his confidants. On the 13th of June, Lord Hastings was arrested by his orders in the council-room at the Tower, and immediately led to execution; and two days after, the Lord Grey, Sir Thomas Vaughan, and Sir Richard Hawes underwent the same fate before the gate of Pontefract Castle. The public were informed by proclamation that these persons had been put to death as having, with the queen and her adherents, 'intended to murder and destroy the Protector and his cousin the duke of Buckingham, and the old royal blood of the realm.' Lord Stanley, the archbishop of York, and the bishop of Ely were also arrested.

On Sunday the 22nd of June, Dr. Shaw preached his famous sermon at Paul's Cross, in which he denounced both the present and the late king as bastards; and on the Tuesday following the duke of Buckingham harangued the citizens to the same effect from the hustings in Guildhall. The next day, Buckingham, accompanied by other lords, by Shaw the lord mayor (brother of the preacher), and by a number of other citizens, proceeded to Baynard's Castle, the residence of the duchess of York, where Richard then was, and in a long address offered him the crown and royal dignity in the name of the three estates of the land. Richard, after some affected hesitation, replied that he felt it to be his duty to obey the voice of his people, and that he would from that day take upon himself the royal estate of the two noble realms of England and France. On the following day, the 26th, he proceeded to Westminster Hall, and there formally declared himself king. The commencement of his reign is counted from that day, though he was not crowned till the 6th of July

Whether it was the fear inspired by the known determination and unscrupulousness of Richard's character, and the executions at London and Pontefract, that operated upon the public mind, or that any considerable part of the nation really preferred his claims to those of his nephew and the rest of his late brother's children, it must be admitted that his accession, so far from having been opposed in the first instance from any quarter, appears to have been everywhere hailed with all the evidences of popular approbation and rejoicing. Part of this favour, if it was not a mere show, he may have owed to the clemency and condescension which he affected as soon as he found himself fairly seated on the throne, and to the expectations of a mild or lax government which the very doubtfulness of his title would excite. But the story, in truth, has been so imperfectly transmitted to us, that it is difficult to weave any consistent or satisfactory theory out of the unconnected details that have been preserved. All we know is, that Richard, having immediately after his coronation set out with his queen on a tour through the northern parts of the kingdom, and having been everywhere received with apparently the most cordial gratulations by all classes, was suddenly surprised, while sojourning at York, by intelligence of a formidable confederacy which had been formed against him by the friends of his two nephews in the southern and south-western counties, with his own chief adviser the duke of Buckingham at its head. It appears that a rising would have taken place immediately throughout Kent, Essex, Sussex, Berkshire, Hampshire, Wiltshire, and Devonshire, had it not been prevented for the moment by its being ascertained that the two royal children were dead. This intelligence however only changed the plan of the conspirators. By the advice of the bishop of Ely, the crown was offered to Henry, earl of Richmond, on condition that he should marry Edward IV.'s daughter the Princess Elizabeth; and as soon as his acceptance of the proposal was received from beyond seas, his partizans called their followers to arms on the same day, the 18th of October, in all the parts of the country where they had influence. But this insurrection was quelled almost as soon as it broke out. Richmond, after having reached the coast of Devon, did not venture to disembark; Buckingham was deserted by a force of Welshmen that he had raised at Brecon, and, falling into the king's hands, had his head immediately struck off in the market-place of Salisbury; of his associates the most fortunate escaped beyond seas; and by the end of the month not an enemy of Richard's remained in arms in England.

A parliament was now summoned, which, having met on the 23rd of January, 1484, immediately passed an Act declaring Richard to be undoubted king of the realm of England 'as well by right of consanguinity and inheritance, as by lawful election, consecration, and coronation,' and bastardizing the issue of the late king Edward IV. by Elizabeth Rivers, whom it designated as the late wife of Sir John Gray, and denied to have any rightful title to the dignity of queen-dowager. This Act is known by the name of the *Titulus Regius*, and is the earliest of what are called the Private Acts, none of which are given in any of the printed collections of the statutes. The *Titulus Regius* however has been printed by Sir Robert Cotton, in his 'Abridgment of the Rolls of Parliament.' This Act was followed by others (also classed as private Acts), attainting and confiscating the property of all the principal persons engaged in the late revolt. But various Acts of public utility were also passed by this parliament; among others, one authorising every justice of the peace to admit a prisoner to bail, and directing that no officer should seize the goods of a prisoner till after his conviction; one regulating the impannelling of juries; one declaring and amending the law respecting the levying of fines; and several relating to commercial affairs, which, if they were not in all points grounded on the most enlightened principles, were at least in accordance with the opinions of the time, and must be regarded as evidences of a considerable interest taken by this parliament in the economical welfare of the country.

Soon after this however Richard deemed it expedient to adopt a new policy. The queen dowager, whom the parliament had just declared to have been only the late king's mistress, he now, in alarm at the projected alliance between her eldest daughter and the earl of Richmond, affected to court as his near and honoured kinswoman; he proposed marrying the princess Elizabeth to his own son Edward; and when that prince died (in April, 1484), and his queen, Anne, who had borne him no other children, soon after suddenly fell sick, he offered to marry Elizabeth himself. And strange as it appears, both mother and daughter went eagerly into this scheme; the princess in particular showed the utmost impatience for the marriage with her uncle, protesting that he was 'her joy and maker in this world, and that she was his in heart and thought,' and fretfully expressing her fears that queen Anne 'would never die.' And at this time she was living as a companion with the poor sick queen! But when Anne at last did die (on the 16th of March, 1485), not without suspicion of poison, his two confidants, Radcliffe and Catesby, succeeded in dissuading Richard from venturing upon this incestuous marriage, which they assured him would excite the popular indignation from one end of the kingdom to the other; and he then took great pains to proclaim that nothing of the kind had ever been contemplated.

He had the preceding year disembarrassed himself of one considerable source of annoyance and distraction by concluding a peace with Scotland for three years; and affiancing his niece, the lady Anne de la Pole, daughter of his sister the duchess of Suffolk, to James III.'s eldest son, the duke of Rothsay, afterwards James IV. (a transaction however which did not issue in an actual marriage). But at home the aspect of things was now becoming more unsatisfactory every hour. He durst not venture in the state of the public mind to call a parliament, and he found himself at once without money and nearly without an adherent upon whose fidelity he could depend. One after another the most eminent of those who had hitherto stood by him fled to France to join the earl of Richmond. At last, on the 7th of August, Henry landed at Milford Haven; and on the 21st of the same month the result of the battle of Bosworth deprived Richard at once of his crown and his life. [HENRY VII., BOSWORTH.]

Richard left at least one natural son, known by the name of John of Gloucester, who, although yet a minor at his father's death, had been already appointed governor of Calais. There is also a romantic story told of a Richard Plantagenet, who died in the parish of Eastwell in Kent, in 1550, an old man of eighty-two, after a life spent as a working bricklayer, and who asserted that he was present at Bosworth Field, where Richard informed him he was his son, but this legend rests on the slightest authority. A natural daughter, named Katherine, is assigned to Richard, who was to have been married to the earl of Huntingdon, but who died in 1484, before she had reached the age agreed upon. The duchess of York, the mother of Edward IV. and Richard III., we may here notice, survived all these events, not dying till 1495.

Both the character of Richard III. and many of the events of his reign have been subjects of dispute among modern writers, some of whom have gone the length of attempting to make out that all the crimes imputed to him are the mere fabrications of his enemies. Much to the effect that Horace Walpole has advanced in his famous 'Historic Doubts,' had been anticipated by Sir George Buck, in his 'Life and Reign of Richard III.,' published as long ago as the middle of the seventeenth century. Buck's work however also contains a considerable quantity of matter not elsewhere preserved, at least in a printed form. The chief original historian of this reign is Sir Thomas More, in his unfinished tract, entitled 'A History of the Pitiful Life and Unfortunate Death of Edward V. and the Duke of York his brother; with the Troublesome and Tyrannical Government of the Usurpation of Richard III. and his miserable End.' There are the Latin annalists, John Rouss, or Rosse, and the continuator of the History of Croyland.

RICHARD PLANTAGENET, Earl of Cornwall, and titular King of the Romans and Emperor of Germany, was the second son of John, king of England, and was born January 5, 1208. He was created earl of Cornwall by his brother Henry III. in 1226; and he figures as one of the leading personages throughout that turbulent and distracted reign, showing generally much moderation and good sense in his endeavours to assuage the stormy contentions between the king and the barons, with whom he occasionally sided against the more outrageous excesses of the royal authority, although, as might be expected, without any participation in the design of abridging the antient prerogatives of the crown, and not without a natural regard in other respects to the interests created by his position. Although he showed some military talent on more than one occasion, his abilities on the whole seem to have been, like his passions, moderate, and of a middle character; he had no pretensions to a brilliant or commanding intellect, but he was at least as far removed from the weak-mindedness of the king his brother, generally evincing in his public conduct at least good sense and discretion, as well as a calm and conciliatory temper. It was a consequence of this moral and intellectual constitution however that, if he had no great vices, he should also be without great virtues; and that the reigning principle of his character should be a cold selfishness, which, though it might shrink from any course of violent aggression upon the rights of others, would yet be active in seeking all safe advantages; and, in that pursuit, would be in danger of sometimes tripping or overreaching itself, notwithstanding all its clear-sightedness and habitual caution. Richard, moreover, if he had no lofty or daring ambition, seems to have had a considerable share of vanity, which also would be apt to assist in betraying him in certain circumstances. If we take these considerations along with us, it will be easy to understand his career. After having first joined the barons who attempted to check the royal despotism, and afterwards more than once interposed successfully as a mediator between them and the king, we find him entirely separating himself from their latter and more decided proceedings; and, in the final struggle with De Montfort and his associates, which put in jeopardy even the possession of the crown by his family, resisting the insurgents as keenly as Prince Edward himself. The most remarkable incident however in Richard's history is his election as King of the Romans in 1256. This honour he is believed to have owed entirely to his great wealth, which enabled him to bribe several of the electors; but it is a matter of dispute whether, after all, the majority of votes was really given to him or, at another election a few weeks after, to his competitor, Alphonso, king of Castile. Richard is commonly reckoned among the German emperors next after William, count of Holland, the successor of Conrad IV.; but some historians distinguish the whole period from the death of Conrad in 1254, to the accession of Rudolph I. in 1273, by the name of the Grand Interregnum. Richard was crowned at Aix-la-Chapelle, and occasionally exercised such of the imperial rights as could be exercised by a stroke of the pen or the expenditure of a little sealing-wax; but he never enjoyed any real authority in Germany, nor indeed did he show himself much in that country. He was taken prisoner by De Montfort, along with the king his brother, at the battle of Lewes, in May, 1264, and was confined in Kenilworth Castle for more than a year. He died at his house at Berkhampstead, on the 2nd of April, 1272.

Richard was thrice married: first, in 1230, to Isabel, daughter of the great earl of Pembroke, and widow of the earl of Gloucester, who died in 1240; secondly, in 1243, to Sanchia of Provence, a sister of his brother's wife, Queen Eleanor, who died in 1261; thirdly, in 1267, to a German lady, Beatrice, daughter of Theodoric de Falkenstein, and niece of Conrad, archbishop of Cologne, who survived him. Of five children which he had by his first wife, and two by his second, all died without issue. His second, and then eldest, son Henry, was assassinated in the church of St. Lawrence at Viterbo in Italy, by Simon and Guy, the two sons of De Montfort, on the 3rd of March, 1271. The earls of Berkeley claim to be descended from a natural daughter of Richard, earl of Cornwall, Isabel, who married Maurice de Berkeley, the father of the first Baron Berkeley.

RICHARD DE BURY was born in 1287, upon the estate of his father, Sir Richard Aungerville, or at Bury St. Edmunds, but it is probable that the predilection which occasioned his taking the name of that place arose from his having received the first rudiments of scholastic education there, from his uncle John de Willoughby, a clergyman. When sufficiently qualified, he was sent to Oxford, where he continued to study till he received the appointment of tutor to Prince Edward (afterwards Edward III.), with the office of receiver of his revenues in Wales. This situation enabled him to afford assistance to his royal pupil in the hour of adversity, for when Edward fled with his mother to Paris, and was distressed for want of money, De Bury secretly hastened to succour him, taking with him a large sum in gold, which he had collected while in office; but his flight being discovered, he was pursued by the king's lieutenant, with a band of twenty-four horsemen, even to Paris, where he narrowly escaped detection by being concealed during seven days in the belfry of the convent of Friars Minors. When Edward came to the throne, the fidelity of his tutor was rewarded by a rapid advancement to dignities both in church and state. He was first made cofferer to the king, then treasurer of the wardrobe and clerk of the privy seal; he also visited Rome twice, as legate to Pope John XXII., and on both occasions was treated with great honour and distinction, being made one of the pope's principal chaplains, and presented with a bull nominating him to the first see that should become vacant in England. His expenses upon the second of these journeys amounted to 500 marks. They could not well be less, considering the splendour of his retinue; for when he went into the presence of the pope and his cardinals, he was uniformly attended by 20 clerks and 36 esquires, all attired in the most sumptuous manner. Whence the means were derived, may be seen in the list of his appointments, which, besides the above named, were, during the first six years of Edward's reign, two rectories, six prebendal stalls, the archdeaconries of Salisbury and Northampton, the canonry of Weston, and the deanery of Wells.

While at Paris, on his return from Rome, he received intelligence that the bishopric of Durham was vacant, and that the king had written to the pope requesting his presentation to that see. It happened that the right of election was vested in the prior and chapter of Durham, who, notwithstanding they had also a letter from the king, proceeded to elect Robert de Graystanes, a monk and subprior of Durham, who was confirmed and consecrated by the archbishop of York, as Bishop Godwin says, with more haste than good speed, for the temporalities were at the king's disposal, and he withheld them till he received the pope's answer, which happened to be dated one day prior to the election of Graystanes, and confirmatory of the appointment of De Bury. Upon this Graystanes was deposed, and De Bury consecrated by the archbishop of Canterbury, on the 19th of December, 1333.

The ready submission to this infringement of the right of appointment by all the parties concerned, has been scarcely remarked upon by those who were not interested in it. In 1334 De Bury was made chancellor and high treasurer of England. Within the three following years he was thrice at Paris as ambassador to the king of France, upon the subject of Edward's claim to the crown of that kingdom, and in the same character he visited Antwerp and Brabant. He had been installed at Durham by proxy, and had once visited the see, but in 1337 he did homage to the archbishop of York. It does not appear when he resigned any of his political appointments, but he probably did not pass much of his time in his diocese till after 1338. When he had leisure, we find him deeply involved in pursuits far more congenial to his taste than politics. Accident made him a statesman, but he was a scholar from habit and natural inclination. In early youth he delighted in the society of learned men, but of books 'in which wisdom is contained' he was an enthusiastic lover and the most distinguished collector of his age. Fortunately for him the king encouraged this disposition, and allowed him to use the influence of office in the promotion of his views. He purchased freely in his travels and at home, where he made himself acquainted with every collection, public and private. Moreover, he says, when it became commonly reported that books, especially old ones, were more precious in his estimation than money, of such new-year's gifts and other presents as it was customary to make in his time, they flowed in abundantly from all quarters. His researches saved many books that would have perished from neglect; and these he caused to be repaired. Such as he could borrow, if they were not for sale, he caused to be copied, for which purpose he had an establishment of book-binders, stationers, and illuminators in his palace. It is said that he finally became possessed of more books than all the other bishops of England put together; but it is a just tribute to his memory to state that his exertions were intended for the public good, and not merely for the gratification of a taste by no means unbecoming, though it was remarked upon as almost peculiar to himself at the time. In a sketch of his will, made shortly before his death, he says he bequeaths all his books to a company of scholars residing in a hall at Oxford, as a perpetual alms-deed for his own soul and for the souls of his parents, and of King Edward and his consort. The books went to Oxford, but Bishop Godwin could not find that he made a foundation there, as it has been stated. The hall in which they were deposited was on the site upon which his successor Hatfield founded Durham (now Trinity) College.

De Bury was not only a very learned man, but a liberal patron of learning, and it is evident that what he calls his extatic love for books was identified with the love of literature, and an ardent desire for promoting the same feeling in others, whom he amply supplied with the means of acquiring knowledge. He regretted the general ignorance of the Greek and Hebrew languages, and took care to provide grammars of both. In searching for elementary books generally, even the village schools did not escape his scrutiny. There is no doubt that De Bury was acquainted with Greek, and he probably learned it at Oxford. Grosseteste, who died in 1253, learned Greek and Hebrew at Oxford, from which it appears that these languages were taught there before De Bury's time. That Greek was taught in England still earlier than Grosseteste's time is also certain. [ROBERT OF LINCOLN.]

The best account of his researches and of his life will be found in the 'Philobiblon,' a small treatise written for the purpose of explaining his objects, of giving directions about books generally, and particularly about his own collections, and even of justifying his conduct, for there were many who derided his pursuits, and thought them altogether extravagant. This tract was first printed at Cologne, in 1473; afterwards at Spires, in 1483; Paris, 1500; Oxford, 1599, and in the collections of Goldast and Schmid; a limited impression of an English translation was published in London, 1832. There is no other known work by him extant, though one is mentioned under the title of 'Orationes ad Principes,' and some letters are spoken of. He certainly had an extensive correspondence with the most distinguished literary men of his time. Petrarch, with whom he conversed, calls him a man of an ardent and enthusiastic turn. He bears an excellent character generally; his wealth was freely bestowed upon the deserving but needy scholar, and he was equally munificent in distributing alms to the poor. His book evinces a benevolent disposition, though we must except against his refusing the use of books to the laity, but his precautions against the abuse of them are worthy of all commendation. He died at Aukland, on the 14th of April, 1345, aged fifty-eight, and was buried with due honours in the southern angle of the cathedral of Durham.

RICHARD OF CIRENCESTER, or *Ricardus Corinensis* (sometimes called the Monk of Westminster), a monkish historian of the fourteenth century, so named from his being a native of Cirencester in Gloucestershire. No traces of his family or connections have been discovered, nor has the exact time of his birth been ascertained, although the superior education which he received has led to the supposition that his family was of the higher ranks. He entered the Benedictine monastery of St. Peter, Westminster, in 1350: his name occurs in various documents in 1387, 1397, 1399, and he is registered in one of the chamberlain's lists preserved among the abbey records, by the name of Circestre. He composed several elaborate works on Saxon and British history, and to increase his knowledge he visited most of the libraries in this country for reference to original manuscripts. He obtained a licence to visit Rome from his abbot in 1391, the original of which is still in existence. It is supposed that he undertook this journey between 1391 and 1397, for he appears to have been confined in the abbey infirmary in 1401, and to have died in that or the following year. His work entitled 'Historia ab Hengista ad ann. 1348,' is in two parts. The first part is from the arrival of the Saxons to the death of Harold. His theological works were, 'Tractatus super Symbolum Majus et Minus,' and 'Liber de Officiis Ecclesiasticis.' But he is chiefly known from his celebrated treatise entitled 'De Situ Britanniæ,' which lay hid in manuscript till 1747, when it was first discovered by Charles Julius Bertram, professor of the English language at the Royal Marine Academy at Copenhagen, who sent a transcript of the whole to Dr. Stukeley, with a copy of the MS. In 1757 Dr. Stukeley published an analysis of the work, with the 'Itinerary;' and other particulars may be seen in the second volume of Dr. Stukeley's 'Itinerarium Curiosum,' and in Whitaker's 'Manchester.' In the same year the original was published at Copenhagen by Professor Bertram, with the remains of Gildas and Nennius, under the title 'Britannicarum Gentium Historiæ Antiquæ scriptores tres Ricardus Corinensis, Gildas Badonicus, Nennius Banchorensis,' &c., 8vo., but this work became scarce. In 1809 an edition was published in London, entitled 'The Description of Britain, translated from Ricardus of Cirencester, with the original treatise De Situ Britanniæ,' with the map and a fac-simile of the manuscript, as well as a commentary on the Itinerary. The discovery of this treatise may be regarded as an æra in the study of British and Roman-British antiquities. The Itinerary contains eighteen journeys which Richard says he compiled from certain fragments written by a Roman general and from Ptolemy and other authors; he mentions a hundred and seventy-six stations (while Antoninus has only 113), some of them a considerable distance north of the wall of Severus, besides which there are numerous chasms which show that many names have been lost or obliterated. The credit and fidelity of Richard have been attacked, but with little success; for wherever the subject has admitted of local investigation, the result has added to the estimation of his authenticity. Gibbon says of him that 'he shows a genuine knowledge of antiquity very extraordinary for a monk of the fourteenth century.' He is frequently quoted by his Latin name Ric. Corin., *i.e.* Ricardus Corinensis.

RICHA'RDIA, the name of a genus of plants belonging to the natural order Araceæ, of which only one species is known, the *R. Æthiopica*. It was introduced into this country from the Cape, under the name of *Calla Æthiopica*, in 1731. It is also found wild at St. Helena. It is one of the most beautiful of Aroideous plants. Its large spathe is pure white, surrounding a spadix which is coloured deeply yellow by its antheriferous flowers. Richardia is a hardy plant, bearing well our mildest winters, and growing in great vigour and beauty in the ordinary apartments of a house. It may be made to blossom all the year round.

RICHARDSON, JONATHAN, a portrait-painter, was born about the year 1665. His father dying when he was only five years old, his mother's second husband articled him to a scrivener; but as his master died in the sixth year of his clerkship, he followed the bent of his inclination, and at the age of twenty became a pupil of John Riley. After leaving this instructor, with whom he studied four years, and whose niece he married, Richardson commenced the practice of portrait-painting, in which, even during the lives of Kneller and Dahl, he obtained great employment, and upon their decease he was considered as the head of his profession in England. The profits of his business enabled him to retire from practice many years before his death, which happened suddenly at his house in Queen-square, Westminster, on the 28th of May, 1745. Hudson, the preceptor of Sir Joshua Reynolds, was his pupil and son-in-law. As an artist, Richardson was one of the best painters of a head that this country had at that time produced, but there his merit ended. He had strength, roundness, and boldness in his colouring; but his attitudes, draperies, and backgrounds are insipid and unmeaning, and the disposition of his subjects shows that he was wholly devoid of imagination. There are a few etchings of portraits by his hand, among which are his own, prefixed to his work on Criticism; John Milton; Alexander Pope, two plates, one of them a profile; and Dr. Mead.

It is however as a writer on art that the fame of Richardson must depend. In 1719 he published two discourses, entitled 'An Essay on the whole Art of Criticism as it relates to Painting, and an Argument in behalf of the Science of a Connoisseur,' in one volume, octavo. This work contains the rules of painting and of pictorial criticism laid down with judgment and precision, and expressed in language both forcible and just. It is truly observed of the above essay by a writer in the 'Pictorial History of England,' vol. iv., p. 733, that it 'should be in the hands of every one who seeks for knowledge of sound principles, and would learn to appreciate the divine excellence of Raffaelle.' In it he makes many admirable remarks upon the various styles of this exquisite painter: his Perugino, his Florentine, and his Roman manner. He also refers with pride to our national treasures at Hampton Court, the Cartoons of Raffaello, and pronounces as to them and the Transfiguration, that as they were the last, so they are the best productions of his hand. The Essay and the Argument, with 'The Theory of Painting,' by Richardson, were published together in an octavo volume by his son in 1773. This latter composition also contains an able criticism on the style of Raffaello, acute observations on the Cartoons, and some valuable notices of the paintings by him in the Vatican. In 1722, in conjunction with his son, he published 'An Account of some of the Statues, Bas-Reliefs, Drawings, and Pictures in Italy, &c., with Remarks by Mr. Richardson, sen. and jun.;' and in 1734 they published together 'Explanatory Notes and Remarks on Milton's Paradise Lost, with a Life of the Author, and a Discourse on the Poem.' In 1776 the son published a volume of poems by his father, but they possess very little literary merit. (Walpole's *Anecdotes of Painting*, by Dallaway, iv., 23-29; Bryan's *Dictionary*.)

END OF VOLUME THE NINETEENTH.
